process of organic reproduction. The power of self-multiplication by division is peculiar to living things, but an actual increase of any substance may be by a process of growth alone, without the aid of self-multiplication. Growth, however, takes place in not-living as well as in living matter; and, fundamentally considered, it means only increase in the quantity of the substance which grows, whether we have to do with the substance of a muscle, with a crystal, or with a complex organic poison. Liebig says: "a substance in the act of decomposition, added to a mixed fluid in which its constituents are contained, can reproduce itself in that fluid." And in illustration Sir Thomas Watson writes: "Thus the virus of small-pox (which virus is formed out of the blood) causes such a change within the blood as gives rise to the reproduction of the poison from certain constituents of that fluid: and whilst the process is going on the natural working of the animal economy is disturbed; the person is ill. The transformation is not arrested until the whole of that ingredient in the blood which is susceptible of the decomposition has undergone the metamorphosis.\*" The specific poison (contagium) does not, however, seem to be immediately reproduced in the blood of the person affected: rather, a set of changes are set up in the blood which ultimately lead to the evolution of such a poison in some parts of the body, either limited or widely distributed; so that, as Mr. Simon says,† "Bowels, skin, kidney, tonsils, are the favourite resorts of the several fever-poisons just as they are the surfaces by which naturally the organic waste of the several tissues is eliminated."‡

There are many organic poisons which undoubtedly produce spreading changes in the blood. Writing from Australia, Prof. Halford says §:—"In fatal cases of snake-poisoning, whether in this colony, India, America, or Africa, it may be stated as a rule, with few exceptions, that the blood loses its power of coagulation and becomes thinner and poorer." After the death of the person "it greedily absorbs oxygen when exposed to the air, and it absorbs it more than unpoisoned blood." Though the precise changes are quite unknown, its constitution is obviously profoundly modified.¶ The rapidity with which the symptoms are produced in the case of snake-bite do not in the least prevent our comparing the effects of snake-poison with those of the contagious zymotic diseases. In some of these the effects have been even more rapidly produced. Speaking of 'the Black Death,' which raged in the fifteenth century, Hecker tells us that, "Many were struck as if by lightning, and died upon the spot, and this more frequently among the young and strong than the old." Again, Dr. Aitken says: "When the cholera reached Muscat, instances are given in which only ten minutes elapsed from the first apparent seizure before life was extinct; whilst instances of death taking place from cholera-poison in two, three, or more hours, are well known to be extremely common.

"Its effect  
Holds such an enmity with blood of man  
That, swift as quicksilver, it courses through  
The natural gates and alleys of the body."

The action of known poisons, whether animal or other, upon the blood and system generally, may therefore be compared with those unknown poisons of the zymotic diseases. The great difference is this. The changes in the blood induced by snake-poison are not such as to

terminate in the elaboration of a similar poison in any part of the body of the person bitten, whilst the bite of a mad dog does lead to changes which culminate in the reproduction of the hydrophobic poison; and similarly with those of scarlet-fever or small-pox—contact with these poisons entails changes which result in an enormous production of similar poisons. There is probably no fundamental difference between the two sets of cases. The malarial miasm of intermittent fever, and the poisonous state of the blood which leads to the production of rheumatic fever,\* as a rule produce effects which are more strictly comparable with those of snake-poison, though there is reason to believe that these diseases may merge into other affections which are admitted to be contagious, as when intermittent or remittent fevers develop in warmer climates under the aggravated form of contagious yellow fever. In this way may the gulf be bridged which seems to separate the effects in snake-bite from those of hydrophobia. As Liebig pointed out, what occurs in the former case may be compared to the action of yeast upon a simple solution of sugar, and in the latter to the action of the same ferment upon a solution of sugar which also contains nitrogenous materials at the expense of which the ferment itself may grow. Thus, then, just as the presence of a crystalline fragment may determine the synthesis of its elements† from a solution in which they are contained, and as the living ferment may bring about that much more complex synthesis which occurs during its growth, so may an organic poison having an intermediate molecular complexity by its contact with the fluids or mucous surfaces of the body, be enabled to determine a series of changes leading to the synthesis of a similar poison.‡

If we find that amongst this class of general or specific diseases some are non-contagious, others only slightly so, whilst the remainder present increasing degrees of contagiousness; that diseases, which sometimes or under some conditions are non-contagious, under others become contagious; and lastly, if we find that even the virulently contagious poisons of some diseases are undoubtedly capable of arising *de novo*, then have we certain reason for the supposition, that the contagiousness or non-contagiousness of particular general diseases is a quasi-accidental feature, and that there is no real difference in kind between the poison of a serpent which does not occasion the production of a similar venom, and the poison of a mad dog which does seem capable of undergoing self-multiplication.§

Let us take a brief survey of some of the facts which are known concerning these specific infective diseases.

Glanders is an affection which is in many respects analogous to syphilis, and is almost, if not quite, as highly contagious a malady. Both these diseases, too, form extremely interesting links between such specific tissue affections as cancer and tubercle, and such infective blood-diseases as small-pox and scarlet fever. Like the former, they are apt to involve the presence of morbid growths scattered in different parts of the body, though, like the latter, they are commonly spread by contagion from individual to individual. However little we may

\* I agree with Dr. Richardson in thinking that this affection really belongs to the zymotic class of diseases. Dengue seems to be a slightly contagious affection somewhat intermediate between rheumatic and scarlet fever. The 'sweating sickness' of the middle ages was considered to be an aggravated epidemic form of rheumatic fever, and so also with the various forms of 'miliary fever.' The contagiousness of these diseases, according to Hecker, seemed to vary in different epidemics.

† Which, as Prof. Graham showed, really exist separately in the solution, since they are separable by dialysis.

‡ Sir Thomas Watson says, in explanation of Liebig's doctrine, "In order, then, that a specific animal poison should effect its own reproduction in the blood, and excite that commotion in the system which results from the formation and expulsion of the new virus, it is requisite that a certain ingredient (analogous to the gluten in the brewer's wort) should be present in the blood, and this ingredient must have a definite relation to the given poison. And he subsequently adds, (*Principles and Practice of Physic*, vol. ii, p. 790):—"This theory of Liebig's offers, then, an intelligible explanation of the curious facts that certain contagious disorders furnish a protection, temporary or permanent, against their own return; that they have a tolerably definite period of incubation, and run, for the most part, a definite course; that some persons are less susceptible than others of the influence of these animal poisons, or not susceptible at all; and that the same individual may be capable of taking a contagious disease at one time, and not at another." The same facts, it may be observed, are almost inexplicable in accordance with any rational rendering of the 'germ-theory.'

§ In snake-bite the symptoms are due to the effects of an habitually poisonous secretion which has a most rapid and deadly action; whilst hydrophobia is due to the effects of an occasional quality of the salivary secretion. This occasional quality, characteristic of rabies, is generally admitted to arise independently in the dog, and yet the poisonous salivary secretion sets up a similar disease in other dogs which may be bitten. Nay, more, this affection at times prevails in an epidemic fashion. Dr. Gavin Milroy says (*Transactions of the Epidemiological Society*, vol. i, p. 173): "Hillary, in his work on *Barbadoes*, described rabies as common in the West Indies. Moseley, having never seen a case of it for a series of years, doubted the correctness of the statement; but, in 1783, it unexpectedly broke out with violence at Hispaniola, and also in Jamaica, where it prevailed from June to the following March. Dogs were seized with it that had no communication with others, and some dogs not brought on shore went mad in the harbours of the island. On *Tropical Diseases*, 1863." There are those, however, who still doubt whether rabies is capable of arising *de novo*. (See Art. in Reynolds's *System of Medicine*, vol. i.)

\* Ch. Robin says, in his *Végétaux Parasites*, 1853, p. 376:—"On a confondu un phénomène grandier et physique de transport de végétal d'un sol sur un autre plus ou moins favorable avec la question de contagion. Celle-ci est au contraire caractérisée par une modification moléculaire lente des substances organiques se propageant de proche en proche, sous l'influence du contact d'autres substances organiques présentant déjà elles-mêmes une modification analogue. S'il y a quelque chose de contagieux dans cette métamorphose, c'est la putréfaction des substances azotées qu'on transporte, et elles déterminent dans les mucus sains une altération analogue à celle qu'elles ont éprouvée. Mais il n'y a rien là qui appartienne en propre au végétal et change lui-même." See also pp. 397, 398.

† Lectures on Pathology.

‡ A similar view has been advocated on more than one occasion by Dr. B. W. Richardson. He says (*Medical Times and Gazette*, November 5th, 1870, p. 539):—"A person suffering from a commensurable disease is poisonous precisely as a cobra di capello is poisonous—that is to say, he is producing by secretion an organic poison, which, if it comes into contact in the right way with a healthy person, will reproduce disease." See also *Trans. of Epidem. Soc.*, vol. i.

§ On the Treatment of Snake-bite.

Dr. Richardson has ascertained that, unlike vaccine lymph, the snake poison becomes weakened by dilution, and similar observations have been made by others. The 'particulate' nature of the poison in vaccine lymph, which has been demonstrated by the critical experiments of Chauveau and Sanderson, is a condition in which it very peculiarly exists in many other contagia.

¶ That such effects are in no way necessarily dependent upon the fact that the poison may contain living elements, as may imagine from the influence of pneumonia, cholera, etc. Nay, more, I have had the most personal experience of the fact that a species of acute cerebral affection, some that resembling hay fever may be produced by emanations from certain *Scenedesmus* worms, even after they had been preserved for two or three years in spirits of wine, and macerated for a time in cedar oil (see *Philosoph. Transact.*, 1868, p. 312). I flatter myself similar, though not so lasting, are produced upon some persons by the smell of powdered *Sp. cucurbitina*.

know concerning the actual origin of syphilis, no doubt seems to remain in the minds of most of those who have studied the question, as to the possibility of producing glanders in the horse. After referring to the highly contagious nature of the affection, Dr. Gavin Milroy says, on this subject: "It is also very generally admitted that glanders is a general as well as a propagable disease; and that it is extremely apt, especially in some seasons, to develop itself in foul, unventilated stables, or (as was often the case during the continental war) in the filthy between-decks of crowded transports."<sup>\*</sup>

Here too may be mentioned such affections as purulent ophthalmia, gonorrhoea, croup, and diphtheria—the two former at least yielding local secretions which are virulently contagious, although assuredly they are not necessarily produced by specific infecting agents. The secretions of croup are only slightly contagious, though those of diphtheria often exhibit this quality to a more marked degree. Yet, even this last is generally regarded as an aggravated form of angina, which is apt to prevail occasionally as an epidemic affection.<sup>†</sup>

Turning now to the infective diseases of a more general character, we find a group of the utmost importance to the surgeon and to the obstetrician—between the members of which there is the closest alliance and even interchangeability—and concerning the possibility of whose *de novo* origin no surgeon or physician can entertain any reasonable doubt. These are erysipelas, puerperal fever, pyæmia, and hospital gangrene—fearful affections, but all only too easily producible.<sup>‡</sup> Not to mention idiopathic erysipelas, which is also a contagious affection, § how frequently does an ordinary inflammation assume an erysipelatous character in certain individuals—more especially in those who are the subjects of renal disease: and yet hospital gangrene, pyæmia and puerperal fever are but different modes in which this morbid process repeats itself in certain constitutions and under certain conditions. How easily erysipelas is set up in some persons by the mere contact of a wounded surface with the fluids of a dead body, is well known; and how fatal and frequent may be the attacks of puerperal fever due to the same cause has been fully established by melancholy experience at the Vienna Lying-In Hospital. Yet that such effects are in no way attributable to, or comparable with, ordinary processes of putrefaction is also a matter of absolute certainty. Again, we know that in certain cases where symptoms of poisoning result from eating mackerel or some shell-fish, these effects are not due to the putrescence of such articles of food. And similarly in reference to the many cases in which symptoms of poisoning have been produced in Germany by sausages, we learn from Liebig that "the sausages are poisonous only at a particular stage of decay, and cease to be so when putrefaction is advanced so far that sulphuretted hydrogen is evolved; the central part being often poisonous whilst the surface is wholesome." There seems every reason to believe that in the changes which may take place in these substances, short of actual putrefaction, a "peculiar poisonous principle is evolved." And so in certain cases, where an *unhealthy process* of suppuration occurs, poisonous products may be generated in a wound, whose absorption into the system is capable of bringing about those general symptoms of blood-poisoning which are characteristic of puerperal fever or of pyæmia. ||

\* *Transactions of Epidemiological Society*, vol. i, p. 175. The same author adds, however: "The converse of the proposition is happily no less true; experience having abundantly shown that its development may be controlled even to absolute prevention by the same simple sanitary rules, the observance of which has banished from our jails and workhouses the disease to which I shall next refer, viz., typhus."

† After referring to the exaggerated notions which were at one time entertained with regard to the contagiousness of diphtheria, Mr. J. Netten Radcliffe (*Trans. of Epidem. Soc.*, vol. i, p. 332) says:—"Subsequent observation has shown, moreover, that contagion plays but a very limited part in the epidemic extension of diphtheria. . . . The times of occurrence of the forerunners of the epidemic, the scattered and disconnected centres of manifestation, and the slow growth, extending over a period of several years, would seem to point to developing causes, slowly originating over the whole, or the greater portion of the surface of the kingdom, and culminating more rapidly in the southern than in the northern districts." Mr. Radcliffe adds, "If we would successfully study the etiology of the epidemic, we cannot disconnect that study from the observation of allied affections prevailing contemporaneously." An examination of the statistics relating to the prevalence, during the same period of scarlet fever, croup, thrush, quinsey, and laryngitis lead to the conclusion that "all the affections allied to diphtheria prevailed epidemically contemporaneously with diphtheria."

‡ Sir William Jenner says (*Practical Medicine of To-day*, 1869, p. 56). "We know that the zymotic element which produces contagious pyæmia may be generated in the frame of man *de novo*. A most important problem to be solved is that of the spontaneous origin of other zymotic diseases."

§ Sir Thomas Watson's *Practice of Physic*, vol. ii, p. 917.

|| Just as contact with particular compounds (e.g., cadaveric poison) seems to favour the production of such poisonous compounds in a wound, so may the presence of carbohc acid tend to hinder those poison-generating changes which are otherwise apt to occur in some wounds. The success which attends the use of carbohc acid may, therefore, be quite independent of its germ-killing powers, or even of its ability to arrest putrefactive processes in general. It has been shown, indeed, to act quite differently with different fermentable fluids. (*Modes of Origin of Lowest Organisms*, 1871, pp. 31-35, and Dr. Dougal's pamphlet, p. 6.)

If we refer, now, to the diseases which are most frequently endemic or epidemic in nature, we find them presenting very different degrees of contagiousness. The communicability of some of these affections seems to vary in different epidemics, and also, even during the same epidemic, in different places. Independently of this individual variability, however, the diseases, looked at as a series, present remarkably different degrees of contagiousness. In some this property seems to be absent, whilst in others it presents a most sure and deadly virulence.

Ordinary intermittent and remittent fevers, are, like rheumatic fever, endemic rather than epidemic, and may, as we know only too well, be developed in almost any individual, and especially in a new comer who ventures into a malarious district. All attempts to connect malaria with the presence of organisms have signally failed; these fevers, indeed, prevail in the most variable sites, and are by no means restricted to marshy districts. Dr. Fergusson says: "The first time I saw intermittent and remittent fever become epidemic in an army was in 1794, when, after a very dry and hot summer, our troops, in the month of August, took up an encampment at Rosendaal in South Holland. The soil was a level plain of sand with perfectly dry surface, where no vegetation existed or could exist, but stunted heath-plants. On digging, it was universally found percolated with water to within a few inches of the surface, which, so far from being at all putrid, was perfectly potable in all the wells of the camp." These diseases, under all ordinary circumstances, are most certainly not contagious, and yet all the best authorities on the subject are agreed that yellow fever, which is capable of being propagated by contagion in circumstances favourable to its extension, is but an aggravated form of remittent fever, as it occurs in warm countries.\* This gradual conversion of a non-contagious into a contagious form of disease, combined with the limitations as to the nature and degree of its contagiousness, which the widest experience compels us to accept, are facts of the utmost importance for those who seek to learn the nature and origin of the contagious influence. And, as almost similar limitations have to be accepted with regard to the contagiousness of cholera and dysentery, it is of the greatest importance to ascertain the nature of these limitations. Facts abound, and speak most plainly to those who will read them dispassionately. Referring to the prevalence of yellow fever on the coast of Brazil, Dr. Mc Kinlay† wrote:—"Almost every person who joined the *Vestal* during the prevalence of fever was affected by it; but no person leaving her, under the disease, communicated it to another, in another place." That is, as he afterwards explained, so long as the affected persons went to a healthy place in which the disease was not prevailing.

Facts of this kind are most notorious; and, when an epidemic of yellow fever occurs on land, it has often been found that there are boundaries at no great distance from the tainted district where the disease has not, and to which it will not, spread.‡ The value of migration from the affected region is a matter of history, and the circumstances which have revealed it have all the value of experiments conducted upon a large scale. "During the epidemic of 1800, at Cadiz, 14,000 persons left that city when the disease became suspected. These people fled to the country, where they remained free from the epidemic; while of the 57,499 who remained, 48,520 were attacked, of whom 6,884 lost their lives." And, again we read §—"It was calculated that from Barcelona, in 1821, about 80,000 persons fled; and, except some who departed with the disease already upon them, or who were on the eve of being attacked, all remained exempt from the reigning malady." But, when individuals from an infected district pass into a region where conditions prevail which are favourable to its spread, or which are themselves capable of engendering typhus or other fevers, then yellow fever appears to be a contagious disease. A good illustration of this is supplied by Sir Gilbert Blane.|| He says:

"On the 16th of May, 1795, the *Thetis* and *Hussar* frigates captured two French armed ships from Guadaloupe, on the coast of America. One of these had the yellow fever on board; and, out of fourteen men sent from the *Hussar* to take care of her, nine died of this fever before she reached Halifax, on the 28th of the same month, and the five others were sent to the hospital sick of the same distemper." So far, there is nothing whatever unusual; but what follows is a good example of the

\* "On Marsh Fever," in *Edinburgh Philosophical Transactions*, vol. ix, p. 274. And yet, concerning this disease, Dr. Milroy says:—"That yellow fever is constantly making its appearance, at intervals more or less distant, in various tropical countries, quite independently of any suspicion of antecedent importation, just as malignant cholera does in Hindostan, does not admit of doubt. In some seasons, from causes which we have hitherto failed to discover, it exhibits a much greater diffusion and migratory power than in other seasons. . . . Malignant cholera is much more diffusible and migratory than yellow fever; few regions of the world have escaped its assault."

† *Monthly Journal of Medical Science*, November 1852, p. 425.

|| *Diseases of Seamen*, p. 606.

kind of testimony which exists as to the occasional contagiousness of the disease. "Part of the prisoners," we are told, "were removed on board the *Husser*, and, though care was taken to select those seemingly in perfect health, the disease spread rapidly in that ship (formerly healthy),\* so that near one-third of the whole crew was more or less affected by it." Now, these facts which are recorded concerning yellow fever, are very comparable with what would have to be stated concerning dysentery. This also is "a disease liable to be engendered at any time by foul, damp air, and the use of bad food and drink, and which, at first, shows little, if any, power of communicability, but which, as cases multiply, and when the sick and the well are congregated together, unquestionably acquires contagious properties".† The same power of arising *de novo*, and the same absence of contagiousness, except under the influence of favouring circumstances, seems to distinguish the direst of our modern epidemics—cholera. As Dr. Gavin Milroy says: "The whole history of the disease proves that contagion plays a very small and subordinate part in its diffusion; and nowhere has the attempt to exclude it by barring intercourse with places already affected succeeded in protecting a country from its invasion." Out of the area in which it habitually exists as an endemic disease, malignant cholera does not seem to be directly generable "by any known or appreciable conditions of local insalubrity, however much these conditions may favour its development or aggravate its intensity when it is once present, or is close at hand." The spread of the disease from its endemic site seems undoubtedly to be influenced by obscure atmospheric or other unknown conditions, comprised under the term 'epidemic influence'. Sir William Jenner asks: "What is the specific cause-relation between cholera and choleraic diarrhoea, and between severe summer diarrhoea and choleraic diarrhoea? Is cholera, in the form of choleraic diarrhoea, always amongst us?" And Mr. Macnamara, in part, replies from Calcutta that "cholerae is simply a modified form of Asiatic cholera, and is capable of engendering this more deadly form of the disease in other people by means of the dejecta." He says, also: "I know that several of the leading practitioners in this part of India are of opinion that cholera is 'a something generated in the bodies of those attacked by it, quite independently of all external influences.'‡"

Turning, now, to such affections as influenza and parotitis, these also are diseases which present various degrees of contagiousness, and are frequently epidemic in their mode of onset. Both are believed to be capable of arising *de novo*, although the spread of influenza is undoubtedly promoted by unknown 'epidemic influences.' Sir Thomas Watson says: "The visitation is a great deal too sudden and too widely spread to be capable of explanation" by mere contagion. He adds: "It has been observed to occur also at the same time on land, and on board different ships, which have had no communication with the shore nor with each other."

If, however, we direct our attention to such affections as typhoid fever, relapsing fever, typhus, the plague, and cerebro-spinal meningitis, we meet with a group in which different degrees of contagiousness are presented, but concerning the origin of which *de novo*, or, independently of contagion, there can now be little doubt. Although this is a doctrine which has long been supported by many who have paid most attention to these diseases, it has of late years been much enforced and strengthened by the investigations of Dr. Murchison. The contagiousness of typhoid or enteric fever is very low; and, as Dr. Murchison says, "although enteric fever is, under certain circumstances, communicable, a large number of cases commence under circumstances which appear to exclude every possible source of contagion. The truth of this observation is almost universally admitted; and it is, therefore, necessary to search for some other cause of the disease than contagion". An

enormous amount of evidence tends to show that emanations from sewage and from some forms of putrefying matter are capable of exciting the disease in those who are favourably predisposed, although in other cases it seems to be more directly communicated by means of drinking water contaminated by sewage containing the dejections from a typhoid patient.\*

Relapsing fever and typhus present many points of resemblance: both are essentially epidemic diseases; both are undoubtedly contagious. They generally occur during seasons of great scarcity, and they prevail more widely amongst the poorest class of the population. Overcrowding and defective ventilation, especially when associated with bad and insufficient food, "not only favour the propagation of typhus, by concentrating the emanations from the sick, but appear to be capable of generating the poison *de novo*." After alluding to the mode in which epidemics commence, Dr. Murchison adds: "I would allude in particular to an epidemic of true typhus which occurred in 1843, at Brouhac, an elevated village in the Canton de Puy, in France. Most of the inhabitants were in a state bordering on starvation; and the first cases were traced to a house where there was overcrowding and no ventilation. It is impossible to conceive that the disease was imported, inasmuch as true typhus was not prevalent at the time in any other part of France.†" With regard to relapsing fever, on the other hand, it has been shown‡ that this (which is essentially the famine fever) is more dependent upon extreme starvation than upon overcrowding. Although it is not always easy to separate these two causes, it has been ascertained that in mixed epidemics of typhus and relapsing fever, relapsing fever is most prevalent towards the commencement, and typhus towards the close, of the outbreak. Then, again, we know that relapsing fever is not confined to large towns, but that it also decimates the starving inhabitants of country places.

Cerebro-spinal meningitis is believed by many to be only a modified form of typhus§, though this is more certainly the case with the plague, in which the typhus poison is evolved in its severest form. Undoubtedly contagious, though formerly believed to be infectious, in the very highest degree, Dr. Gavin Milroy says: "The whole history of medical opinion on the subject of the plague affords one of the most remarkable instances on record of fanciful speculation taking the place of sober and careful inquiry." And then he adds: "That the plague has frequently become developed *de novo*, and quite independently of any antecedent infection, cannot be doubted. The recent outbreak at Bengazi, on the Barbary coast, only confirms previous testimony; and as this outbreak occurred after many years' disappearance of the pestilence in that place, as well as throughout Egypt and Turkey generally, no other interpretation is possible. Then, as on many other occasions, the disease sprung up

\* Referring to the views of Dr. W. Budd and others as to the disease being propagated only by sewage which is contaminated by typhoid stools, Dr. Murchison says:—"Admitting fully that this view offers the best explanation of those cases where the fever is propagated by the sick, many, if not most, of the facts adduced in its support are explicable on the theory of spontaneous generation, while in the others the mode of transmission is less clearly established than might be desired. On the one hand, facts are adduced to show that the disease is contagious; and, on the other, cases are mentioned to demonstrate the intimate connection between its origin and bad drainage. The evidence, however, is still insufficient to prove that the stools of the sick have constituted the medium of communication. This conclusion, it seems to me, has been jumped at from the unwillingness to admit that a communicable disease can ever have a spontaneous origin. But, in the second place, there are many facts which show that enteric fever often arises from bad drainage, independently of any transmission from the sick. As long as the current flows freely through a drain, there is little danger of the emanations from it giving rise to enteric fever. The danger arises when the drain becomes choked up, when the sewage stagnates and ferments." The dejections from a typhoid patient being remarkably prone to undergo decomposition, Dr. Murchison adds: "It is possible that the stools of enteric fever are more prone than ordinary sewage to the peculiar fermentation by which the poison is produced, and that even in certain cases the fermentation may have commenced before their discharge from the bowels. In this way, enteric fever may occasionally be propagated by the stools, but even then it seems more probable that the poison is always the result of decomposition, than that it is derivable from a specific erudition like that of small-pox." ("On the Causes of Continued Fevers," in *Lond. Med. Rev.*, 1864.)

† Dr. Murchison very aptly remarks:—"It has been the custom with many writers to refer epidemics of typhus to some subtle 'epidemic influence'; and thus when a failure of the crops has been followed by typhus, both of these disasters have been ascribed to a common atmospheric cause. But of such atmospheric influences, capable of producing typhus, we know nothing; their very existence is doubtful, and the employment of the term has too often had the effect of cloaking human ignorance, or of stifling the search after truth. If typhus be due to any 'epidemic influence', why does this influence select large towns and spare the country districts? Why does it fall upon large towns in exact proportion to the degree of privation and overcrowding among the poor?" (*loc. cit.*) Still, although the prevalence of typhus fever may be in great part accounted for without resorting to unknown 'epidemic influences', it must not be supposed that there are no unknown cosmical influences which have to do with the outbreak and spread of various epidemic diseases. Let us rather admit that which seems so probable, and live in the hope that we may one day ascertain more concerning their nature.

‡ See *Continued Fevers of Great Britain*.

§ Doubts, however, are entertained on this subject. (See Mr. Radcliffe's article in *Reynolds's System of Medicine*, vol. ii.)

\* That is, from fever, yellow fever.

† Dr. Gavin Milroy, *loc. cit.*, p. 176.

‡ A treatise on Asiatic Cholera, 1870, p. 127. It is only fair to add, however, that Mr. Macnamara does not give his assent to this view. He is a firm believer in the communicability of cholera. He admits that 'sporadic cholera' is easily generated *de novo*, and that 'cholerae', from which it is often quite indistinguishable, is capable of giving rise in others to malignant cholera; and yet he wishes to maintain the communicability of the latter form of the disease. Other affections also exhibit a double degree of communicability, and it would seem to us that 'sporadic cholera', which is easily generated in certain parts of India, cannot be really distinct from cholerae.

§ Dr. Martin says *Internal Matter and the Contact Theory*, 1867, p. 70:—

"A common contagious disease is recorded by Harvey to have arisen on board the *Swallow*, which, after having been characterized by glandular and diffuse cellular inflammation, by eruptions and phlegm, by erysipelas, and by mumps."

¶ Principles and Practice of Fevers, vol. ii., p. 4. Where examples are given. On this subject, also, Dr. Gavin Milroy says: "It has been confidently stated that every known remission of the epidemic in the Paris hospitals has been preceded by the arrival of a vessel or vessels from the north, when it was prevailing there. But such a statement must not be too readily received, as it is well known that other islands, equally distant from any continent, have been visited, quite independently of arrivals therefrom." See also the articles by Dr. Parker on this disease in *Reynolds's System of Medicine*, vol. i.

amongst want, wretchedness, and squalor, and its true nature was not recognised for many weeks, in consequence of its close resemblance to ordinary typhus, to which it seems to be nearly allied.\*

Now the remaining members of the group of specific infective diseases are varicella, hooping-cough, measles, scarlet fever, and small-pox. The knowledge which we possess concerning the mode of origin of these otherwise than by infection is almost *nil*. They differ amongst themselves, it is true, as regards their degree of infectiousness; but, as others have suggested, they are probably more strictly dependent upon individual states than upon external conditions, and, consequently, are more baffling to those who attempt to fathom their causes. Measles, scarlet fever, and small-pox, are undoubtedly amongst the most contagious of diseases, and, therefore, the chances are always strongly in favour of their contagious origin in any given case. But should this satisfy us? Should we be content to say that even measles, scarlet fever, and small-pox, are propagable only by means of contagion, and cannot arise *de novo*? Are they not strictly comparable with many other general infectious diseases which undoubtedly arise 'spontaneously'? Do we not see amongst those which may so arise that the degree of contagiousness is altogether variable? Does not this seem gradually to increase in each affection, as the off-cast particles have tendencies to undergo molecular change which are more and more capable of initiating chemical actions of a spreading character in the blood or mucous surfaces of ordinary individuals? And does not the diminishing contagiousness of different diseases seem to be due to the fact that off-cast particles are less and less capable of acting upon the healthy fluids and mucous surfaces of the body, but require that these should be altered, now by one set of agencies affecting the general health, and now by another, before such particles can initiate those changes which lead to the evolution of one or other of the specific poisons within the body? Hooping-cough, measles, scarlet fever, and small-pox, would in this case be merely the last terms of a series, differing from the other members simply in degree, but not in kind—and therefore as capable of being generated *de novo* as either of the others, although much more capable than they are of being disseminated by means of contagion.

If we reject this notion, what remains for us? The germ-theory is quite untenable—the analogy which has been thought to exist between the causes and nature of certain diseases and the specific and unalterable characters of living organisms is erroneous in both its aspects. And even if the diseases are *now* only propagable by contagion, just as the higher living things are propagable by reproduction, they must nevertheless have originated once; and, if once, why not now? Or, declining to admit even so much, shall we refuse to bear our own burdens? Shall we shift the difficulty, and suppose that the poisons of syphilis, measles, scarlet fever, small-pox, and other diseases, have been evolved amidst the unknown conditions obtaining upon the surface of an unknown world, whose disruption has scattered them broadcast, and conveyed them to us, with other never-dying germs, upon the verdant surface of a "moss-grown fragment"? With such alternatives, surely our choice cannot be doubtful.

If we turn to a sober survey of the facts which lie before us concerning the infective diseases as a class, our difficulties will be much diminished: simple and obvious conclusions will appear. (See Table.)

In the first place, we find a group of diseases due to the presence upon or within the body of parasitic organisms. These are partly local and partly general affections, the latter being intensely contagious, and on that account frequently confounded with other general infectious diseases in which living organisms do not occur. These general parasitic diseases are propagated by the presence and multiplication of living units, whilst those of the next great class are not.

\* Transactions of Epidemiological Society, vol. v, p. 174. This is generally the rule with regard to epidemics. They occur mostly at times when other ordinary or non-specific affections to which they are most closely related are prevalent. And during the period of their decline, the more virulent epidemic forms of the affection again seem to lapse into more ordinary forms of disease.

† It seems to me that at present the facts are looked at much too exclusively from one point of view. It is fully admitted by many persons that during epidemics, more especially, a large number of cases of small-pox occur, even in isolated situations, in which it is quite impossible to obtain any evidence of contagion. When we consider, further, that the disease is epidemic at times, and then almost dies out, although multitudes remain who might be infected, we must admit that something besides contagion is undoubtedly operative in facilitating its spread during these times, and therefore we may assume it to be possible that this 'epidemic influence' of itself might, in certain persons, suffice to engender the disease without contagion. Dr. Gavin Milroy (*loc. cit.*) says: "This most interesting subject has not been investigated with that patient and searching care which all physical problems demand. The prevailing negative belief rests on merely presumptive grounds, rather than on sifting inquiry. That outbreaks of measles, hooping cough, etc., have been observed in various remote islands, and at distant intervals of time, without any traceable connexion with previous cases, either in the country itself or amongst recent arrivals, can scarcely be doubted. Hillary particularly alludes to his having noticed such occurrences in Barbadoes; and the medical history of other West India islands would afford, I believe, similar evidence." See also Hecker's *Epidemics*, pp. 215-218.

# PARASITIC DISEASES AFFECTING:

External (cutaneous) surface.  
Internal (mucous) surfaces.  
Closed (serous) cavities.  
Tissues of organs or parts. (*Psorospermia*, *Cysticerci*, *Nematoids*, etc.)  
Blood. (*Bacteridia* in 'Malignant Pus-tule', *Psorospermia* in 'pebrine', etc.)

Caused and propagated by the presence and self-multiplication of living units.

## TISSUE DISEASES.

### A. Diseases of Internal Formed Tissues and of Mucous Membranes.

Fibro-plastic growths.  
Cancerous growths.  
Tubercular growths.  
Glanders.  
Syphilis.  
Gonorrhoea.  
Purulent ophthalmia.  
Diphtheria and Croup.

Principally sporadic.

### B. Diseases of the Blood (principally).

Erysipelas.  
Puerperal fever.  
Surgical fever.  
Pyæmia.  
Hospital gangrene.  
Rabies.  
Rheumatic fever.  
a. Dengue.  
b. Sweating sickness.  
Intermittent fever.  
a. Remittent fever.  
b. Yellow fever.  
Summer diarrhoea.  
a. Choleraic diarrhoea.  
b. Cholera.  
Dysentery.  
Influenza.  
Mumps.  
Relapsing fever.  
Typhoid fever.  
Typhus fever.  
a. Cerebro-spinal meningitis?  
b. Plague.  
Varicella.  
Hooping cough.  
Measles.  
Scarlet fever.  
Small-pox.

Principally Endemic.

Often Epidemic.

Caused and propagated by chemico-physical agencies, and not by the multiplication of living units.

The tendency in the former is towards death; the tendency in the latter towards recovery. The non-parasitic infective or specific diseases are also partly local and partly general affections. The local affections are closely allied to other morbid states, such as cancer and tubercle, with which they are not usually classed. Many of these local diseases tend to become general diseases. Similar morbid growths spring up in various parts of the body, and the blood itself becomes affected. They are also more or less apt to spread from individual to individual. All are capable of being generated *de novo*. Such local affections are united by the closest bonds of similarity to the more general zymotic diseases, amongst which all degrees of contagiousness are manifested. The members of the whole series, however, are intimately related to one another; and their mode of propagation is essentially similar, even though the readiness with which contagion occurs is variable. Very many of them are undoubtedly generable *de novo*; and the others are probably also capable of arising 'spontaneously', though the proof of this, on account of their highly contagious nature, is difficult to establish.

All these latter diseases, therefore, are dependent upon local perverted modes of growth, or upon chemical changes of a definite, though unknown, character taking place in the blood—partly under the influence of general causes, and partly owing to the initiation of chemical changes induced by contact-action of contagious particles or fluids. As with diseases in general, so with these, two sets of factors are frequently concerned in their production. There are the 'predisposing causes' pertaining to the condition and tendencies (either inherited or acquired) of the individual, and there are the 'exciting causes' or external influences (usual or unusual) at the time operative upon this individual. The combined influence of these causes of disease are often called into play in the production of the infective malady, just as much as they are influential in the origination of non-infective diseases. But predisposing causes may, in conjunction with ordinary external agencies, suffice in some cases; just as, in other cases, the exciting cause or causes may be capable of initiating the affections in the average healthy individual, without the aid of any predisposition.

Unless we entertain opinions of this kind, facts which are admitted by all seem quite incapable of being explained, whether they have

reference to the 'generalisation' of morbid growths within the body, or to the spread of infectious diseases amongst the community. Cancerous particles in the circulation are inoperative in certain individuals, or in many parts of other individuals, however numerously they may exist. Contact with the contagia of ophthalmia or diphtheria will excite the disease in some persons and not in others. Yellow fever and cholera are 'contagious' only when certain favouring conditions are present to facilitate the operation of the specific poisons of these diseases. Rabies cannot be communicated to certain dogs. Professor Gamgee\* mentions a case in which a pointer did not contract the disease although it was bitten seventeen times by mad dogs. And, even the most contagious affections—those in which the poison is usually sufficiently potent to act upon the average individual—does not seem capable of being communicated to some persons. Do we not see individuals fully exposed to the contagion of measles, scarlet fever, and small-pox, and yet fail to contract the disease? Facts of this kind are familiar to all medical men. Sir Thomas Watson has referred to the case of "an old woman who for years had been in the habit of going from village to village as a nurse; and of nursing a great number of persons labouring under small-pox, which she had never had, and against which she (naturally enough) believed herself proof": but, he adds, "at length she was taken ill, and died of small-pox in the eighty-fourth year of her age." Again, he says: "In 1845, a lady with whom I am acquainted went through an attack of measles, that disease being prevalent in the village where she was then residing. She had never had the measles previously; yet she had long before personally tended eleven of her twelve children when ill of the same complaint."†

Such facts are quite inexplicable in accordance with the vital or 'germ-theory' of causation of these diseases,‡ though they become much more easy to understand in accordance with the views which have just been laid before you. They are, further, thoroughly harmonious with the results of experiments made by myself and others with reference to the causes of fermentation. These have led me to reject, as too narrow and exclusive, the 'vital theory' of Pasteur, and to adopt the broader physico-chemical doctrines of Liebig, which appear to be harmonious with all the facts. In endeavouring to explain the initiation of fermentation in any particular fluid which has been boiled, we have also to consider the influence of intrinsic tendencies in the fluid, in combination with the exciting or external agencies to which it is subjected. In some cases, the intrinsic tendencies may of themselves be potent enough to initiate the process; whilst in other instances the mere contact-action of an unheated organic fragment combines with weaker inherent tendencies to incite the fermentative process.§ Fermentations may be associated with the presence of organisms, or they may occur independently. The ordinary zymotic diseases are comparable with fermentations of the latter class; and their several contagia act after the fashion of the mere dead organic fragment upon the fermentable fluid.||

\* In *Reynolds's System of Medicine*, vol. 1, p. 717.

† *Principles and Practice of Physic*, vol. II, p. 782.

‡ The lowest kinds of living germs with which the hypothetical disease-germs are compared, will live and flourish in various media, and will infallibly set up fermentative changes in those which differ very considerably from one another. The contagionism of general putrid diseases also manifests itself equally well upon persons of all ages, and at all times.

§ I look, again, at the great moral epidemics which were so prevalent in the middle ages, and which in their most marked form have extended almost to our own times. Here, also, we have a changed mode of action in certain parts of the body, brought about partly by 'predisposing', and partly by 'exciting causes'. We may read in Hooker (*Epidemics of the Middle Ages*, p. 149) as follows: "In a Methodist chapel in Redruth, a man, during divine service, cried out with a loud voice, 'What shall I do to be saved?' at the same time manifesting the greatest uneasiness and solicitude respecting the salvation of his soul. Some other members of the congregation followed his example, cried out in the same form of words, and seemed deeply affected to suffer the most excruciating bodily pain. This strange occurrence was soon publicly known; and hundreds of people who had come thither, either attracted by curiosity, or by a desire, from other motives, to see the sufferers, fell into the same state. The chapel was soon open for some days and nights, and from that point the new epidemic spread, with the rapidity of lightning, over the neighbourhood of Cornwall, Devon, Dorset, Devon, and Palmouth, as well as over the adjacent islands. When this alarming increase in some measure abated, it was again renewed, and it continued itself throughout to the Methodist chapel. It was only by the terrible which has been mentioned and contagious that it was arrested, and it was not until the end of the last epidemic. These were the signs and symptoms of the greatest plague, and fell into convulsions. According to a narrative contained in some papers, within a very short time, and with the most perfect facility." The various signs and symptoms of the epidemic were then described.

|| It is, however, quite possible that, in certain cases, this change in the blood might be the last stage of the disease, and that a character so far from being the exception of *Bacteria* in the blood, that it is a common occurrence during life. I have already mentioned very many cases of this kind. In two cases, one of them the blood was found to be very thick, and the temperature had risen to 102° F. In a few hours the patient died. I found the vessels of the brain and other parts of the body containing a great number of *Bacteria* even within forty hours after death, and whilst the temperature of the air had not been over 64 deg.

Some boiled fluids are quite incapable by themselves of initiating a fermentative process; but this tells no more against the positive abilities of other fluids, than does the fact that certain diseases are unable to spring up amongst a particular community, tell against the circumstance that they do so arise amongst other communities where a number of unhygienic surroundings, previously absent, are also operative in producing the result.\*

Amongst the 'exciting causes' of disease, there must be many which are to us at present utterly obscure. More especially is this the case with epidemic diseases. There are, undoubtedly, 'epidemic influences' concerning which we know scarcely anything, but whose existence is only too surely attested by the history of the great epidemic and zymotic affections. As Fleming says, in his *Animal Plagues*, "it has been a matter of common observation from the earliest times, and our history will testify to its accuracy, that wide-spread pestilence in plants, and murrain in animals, have frequently either preceded, accompanied, or followed closely on those visitations which caused mortality and mourning in the habitations of men; showing an identity of causation or affinity, which strongly tempts the inquirer to solve the secret of their joint production."† 'Causes' of this kind, however obscure, are undoubtedly none the less real. Whilst we may hope, therefore, that increasing knowledge will ultimately enable us to throw more light upon their nature, we may at least feel assured that the efficacy of these 'causes' may be increased or diminished by us at will. 'Exciting causes' of all ordinary severity require to be supplemented by the action of 'predisposing causes' existing in the individual himself before disease can be generated. Although we are comparatively powerless to rectify mere individual idiosyncrasies, of the very nature and existence of which we may be ignorant, still these constitute a mere fractional part of the predisposing causes which favour the spread of epidemic affections. These are, in the main, produced in the individual by the operation of the more general exciting causes of disease, such as bad or insufficient food, bad water, and impure air; or they are dependent upon more special causes, such as depressing emotions, excessive muscular exercise, or the occurrence of any unusual amount of degenerative changes within the body. As Dr. Carpenter pointed out nearly twenty years ago, in a very able article on the 'Predisposing Causes of Epidemics', these causes are reducible to one or other of three categories: "1, those which tend to introduce into the system decomposing matter that has been generated in some external source; 2, those which occasion an increased production of decomposing matter in the system itself; and 3, those which obstruct the elimination of the decomposing matter, normally or excessively generated within the system, or abnormally introduced into it from without." Now, the common characteristic here is that "any one of these causes will tend to produce an accumulation of disintegrating azotised compounds, in a state of change, in the circulating current"; and observation seems to tell us that either of the causes leading to such a result may, when potent, suffice to assist the spread of epidemic diseases, though two or more in combination lead to much more certain results. Much has been done to diminish the prevalence of these conditions,

Fahr. The blood was blackish and fluid, the organs were much blood-stained, and in addition to other marks of putrefaction, bubbles of gas were abundant in the meshes of the pia mater. The blood of such, and of other similar patients examined during life, have never revealed to me the least trace of *Bacteria*. Dr. Burdon Sanderson, moreover, has ascertained that the blood and other fluids of the body do not generally exhibit any zymotic tendencies (see *Thirteenth Report of Medical Officer of Privy Council*). Some of the *Bacteria* which were found after death, I believe to have been evolved *de novo*, whilst others were descendants of those which had so arisen, in the putrescent blood. No other view seems to me to be so tenable as this. The fluids in a pyemic abscess may occasionally be on the road towards similar results, and even if no *Bacteria* exist, such fluids might exhibit 'zymotic' properties.

\* There is, however, a great tendency to draw such conclusions; just as there is a tendency with others to conclude that *Bacteria* do not arise *de novo* because there is no evidence of such an occurrence when dealing with Pasteur's solution or a few other fluids, different from those in which the process is stated to occur. Let any person, for instance, repeat Dr. Sanderson's thirteenth experiment (*Thirteenth Report of the Medical Officer of the Privy Council*) with a strong infusion of hay or turnip, rather than with Pasteur's fluid, and then such results will occur that, from Dr. Sanderson's data, he will have no option but to admit that *Bacteria* do arise *de novo*. It is surprising that such an experiment was not tried in the face of all that has been said concerning the productivity of such fluids. The real laws by which contagion is regulated can never be adequately understood unless one knows whether the contagia with which one is concerned can, under any circumstances, arise *de novo*. This seems to me to be the point which should be first ascertained.

† If additional reasons were needed to enforce the vast importance of the fullest knowledge concerning these diseases, they are not wanting. The same author writes: "The losses from only two exotic bovine maladies ('contagious pleuropneumonia', and the so-called 'foot and mouth disease') have been estimated to amount, during the thirty years that have elapsed since our ports were thrown open to foreign cattle, to 1,357,750 head, roughly valued at £8,500,814. The late invasion of 'cattle plague', which was suppressed within two years of its introduction, has been calculated to have caused a money loss of from five to eight million of pounds."

‡ *British and Foreign Medical-Chirurgical Review*, 1853, vol. xi, p. 175.

which act only too surely upon the individual in arousing the 'predisposing' causes of disease, though far more still remains to be done. Happily, however, public attention is now becoming slowly aroused to the importance of pure air, pure water, efficient drainage, and wholesome food, as instruments for maintaining the health of the community.

Let us not be blinded, however, by any narrow or exclusive theories which would teach us that epidemic and infective diseases cannot arise *de novo*. Let us, instructed by a broader survey of the facts, assign no such limits to natural possibilities, and not lightly accept theories which lead to supineness, when we ought to be stimulated to exertion. Whilst accepting to the full all doctrines which inculcate the necessity of diminishing the chances of contagion by every available means, let us, full of hope, diligently seek also for the causes which engender even the most contagious of diseases. Prevention of disease is the grand end and aim of medicine; if, then, we have learned from the sad lessons of experience that scarlet fever and small-pox are virulently contagious diseases; if, even in ninety-nine cases out of a hundred, or even in a still larger ratio, both of these diseases are acquired by contagion, then is it all the more important that we should strive to ascertain what are the invariable and immediately antecedent sets of conditions, or states of system, which suffice actually to engender these maladies. In such cases knowledge and power are most frequently convertible terms. Next to typhus fever, the most fatal of the infective diseases which occur in this country are scarlet fever, small-pox, measles, and whooping-cough. The ravages of typhus in our crowded cities and in our jails have been enormously curtailed, not so much because of its diminished spread by contagion, but rather because we have learned what are the causes which engender it, and are therefore better able to prevent its occurrence. Let us strive, then, to acquire a similar knowledge concerning scarlet fever, small-pox, measles, whooping-cough, and other contagious diseases, and so endeavour, in the most efficient manner possible, to check the ravages of these *morbi populares*.

Time will not permit me even to allude to the many other interesting and important problems which still remain to be solved in reference to these diseases. What I have said, however, will, I hope, suffice to inspire you with a sense of the great difficulty of the problems which you will subsequently have to face; and, therefore, to make you feel the urgent need for diligent, patient, and honest work all through your career—without which you will not be able conscientiously to accept the high responsibilities that will subsequently devolve upon you as practitioners of medicine, and without which no real advance in knowledge can ever be made.

\* Mr. J. Netten Radcliffe says (Ranking's *Abstract*, vol. xli, 1865): "The Registrar-General's returns of scarlet fever for the whole of England, include two periods of five and sixteen years respectively. The first period extends from 1838 to 1842, and the second from 1847 to 1862 inclusive. The total number of deaths registered from the disease in the twenty-one years was 310,720; the annual average mortality for the whole series of years was 14,796." ... "The history of the progress of scarlet fever in the metropolis differs from that of the entire kingdom in this, that it shows a great augmentation of the mortality from the disease in the last quarter of a century. The annual average mortality from the malady in London during the past twenty-six years was 83 per 100,000 population. The average varied from 32 in 1841 to no less than 174 in 1863. In the quinquennium 1839-43 the annual average was 78; in the quinquennium 1844-48 it increased to 88; in the quinquennium 1859-63 it advanced to 115. The death-rate of 1863 (174) was more than double the annual average of the twenty-six years, 1838-64."

#### UNIVERSITY OF CAMBRIDGE.

**ANATOMY AND PHYSIOLOGY.**—Professor Humphry gives notice of lectures and practical teaching as follows. Lectures on Anatomy and Physiology in the new Museums, on Tuesdays, Thursdays, and Saturdays, at 1 P.M., commencing on Saturday, October 21st.—Lectures on Practical Anatomy on Mondays, Wednesdays, and Fridays, at 6 P.M., commencing on Monday, October 16th. These, together with the Lectures on Anatomy and Physiology, constitute the course for M.B. and M.C., and for the Royal College of Surgeons.—Microscopical Demonstrations on alternate Tuesdays, at 6 P.M., commencing on Tuesday, October 31st.—Practical Histology on Saturdays, at 11.30 A.M., commencing October 28th. This, in conjunction with the Practical Physiology by Dr. Michael Foster, constitutes a course of Practical Physiology.—Superintendence of Dissections daily.—Instruction on Practical Anatomy will be continued in the Christmas vacation.—The Downing Professor of Medicine (Dr. Fisher), or his deputy (Dr. Latham), will deliver a course of lectures on *Materia Medica* and Therapeutics during the ensuing Michaelmas and Lent terms. The lectures during the Michaelmas term will be delivered in Downing College, on Tuesdays, Wednesdays, Thursdays, and Saturdays, at 9 A.M., commencing on Tuesday, October 24th; and during the Lent term on Tuesdays and Saturdays. Fee for the course, £3 : 3. The Museum of *Materia Medica* at Downing College is open daily to all students of medicine.

## ABSTRACTS OF INTRODUCTORY ADDRESSES

DELIVERED AT

### THE METROPOLITAN AND PROVINCIAL SCHOOLS,

On OCTOBER 2nd and 3rd, 1871.

#### ST. MARY'S HOSPITAL.

THE introductory Address was delivered by Dr. ALFRED MEADOWS, Physician-Accoucheur to the Hospital and Lecturer on Midwifery.

The lecturer commenced by defending the system of the delivery of introductory addresses, which, like other institutions, had become subjected to the "ruthless scrutiny of the nineteenth century", and had indeed been tried and condemned at one of the oldest of the metropolitan schools. He thought that "one obvious use of these introductory lectures is the tendency which they have to keep alive that bond of Freemasonry which ought to exist between all the members of a profession such as ours, and notably between the pupils and teachers of each medical school. It is almost the only occasion in the academical year on which, being free from other collegiate duties, we, teachers and pupils of all years, meet together for the special purpose of being together, and for the mutual interchange of thought with thought."

Referring to the changes which had taken place in the school during the past year, Dr. Meadows said: "By the mere lapse of time (we may indeed be thankful it is from no other cause), we have to regret the partial loss of three of our most distinguished colleagues—Dr. Sibson, Dr. Tyler Smith, and Mr. Lane. I say partial loss, because their names are still on our staff, their hearts are yet in the place and in the work, and their spirit still energises the labours of their successors. We have also to regret the loss of Dr. Russell as Lecturer on Chemistry, and of Dr. Payne as Lecturer on Pathological Anatomy. But we can generously afford to congratulate the schools of St. Bartholomew and St. Thomas, which have gained their services, while we welcome their successors—Dr. Wright to the Chair of Chemistry, and Dr. Reginald Stocker as Medical Tutor and Pathologist, an appointment now for the first time made in this school. In the latter, we believe that a colleague has been found to whom you will feel more than ordinarily grateful, if you will use him as he would wish you to do."

The lecturer explained the duty of the office of medical tutor, to which Dr. Stocker had been lately appointed, to be that of assisting the students in their studies—"to help them to use their eyes, their ears, their hands, and above all, their understandings". The instruction conveyed by the medical tutor was, in a measure, a substitute for that gained by apprenticeship—the nearly complete discontinuance of which Dr. Meadows regretted. He referred also to the lately instituted scholarships in Natural Science; remarking that there was an obvious fitness in the foundation of such scholarships in a medical school, inasmuch as no one could doubt the enormous value to the practitioner of medicine of a thorough acquaintance with natural science, and at no time could this be so well acquired as at the commencement of medical study.

Leaving matters of local interest, and turning to the question of the selection of a subject for discourse, Dr. Meadows referred briefly to the relations of medicine to science in general, to society, to politics, and to theology. Regarding its social aspects, he observed: "It may be said, in truth, that society itself could not exist independently of the profession of medicine. In political life, also, the medical profession is yearly growing in influence and importance; and no politician can, with any hope of success, aim at influencing the government of the country if he be indifferent to the value of medical opinion in public affairs. Indeed, I have the best reasons for knowing that the political leaders of both sides of the house would gladly welcome a much larger number of medical men to the House of Commons than at present belong to it."

After a few more remarks, the lecturer proceeded to comment on the relations of science to religion. "We hear a good deal nowadays, and some people seem to take a special delight in talking about the conflict between science and religion. Now, I am not one of those who believe that true science is, or can be in any way or degree, opposed, either in theory or in fact, to what is called revelation. I have too strong a faith in the latter, and too high a love for the former, ever to believe in such a possibility, or to entertain the shadow of a doubt as to their complete oneness in all essentials. It has always appeared to me a simple impossibility that true science and revelation should ever

contradict each other. Speculative science, or, perhaps, I ought rather to say, speculative thought, may, and very possibly will, be frequently at variance with revealed truth. But true science, real scientific thought, and most of all the demonstrative facts of science, never have done, and never will do, violence to the undoubted will of the Creator, as exemplified in his revealed word. Reason herself revolts from such a thought. For what are we to understand by the terms science and revelation? It seems to me impossible to deny that, in regard to their relation to the Great Architect of the Universe, they are and must be absolutely identical. Science I take to be the discovery or demonstration of abstract truth in the laws which govern the natural world, and making deductions therefrom. But those laws must have had a lawgiver: there can be no such thing as self-made law: the very idea is an absurdity. Law, then, implies a lawgiver; and he who created the law must also have created that which the law governs, whether it be in the organic or inorganic world, in the animal or vegetable kingdom. In short, the whole realm of what we call Nature, governed as it is by law, witnesses to the Lawgiver as the author of its dynamical agency, while at the same time the material Universe, as we now see it, is a necessary consequence of the operation of law.

"On the other hand, revelation is nothing more than the proclamation, through certain specified channels, of the laws of the machinery, if I may say so without irreverence, by which God wills to govern the moral world, and to bestow upon man a higher existence than his present life. In fact, if I might venture upon a parallel, I should say that revelation is the scientific authority for the moral law, just as the recorded observations of facts in Nature become the scientific authority for natural law. Both authorities are of equal value as bases of truth and as expressions of the Divine will; and just as ignorance of natural science engenders among the proud and foolish contempt for scientific things, so ignorance of theological science is apt to engender, with the intellectually proud, indifference to sacred things.

"In trying, then, to discover the secrets of Nature, to unfold her laws, and to lay bare her operations, we are all the while endeavouring, though we know it not, to extract, as it were, more and more of the Mind of the Creator as it lies hid in the works of His Hands. But what, I ask, is this but an attempt to complete another revelation? And can we suppose that He, who is the author of the written revelation of His will, will contradict Himself in that other revelation which man is permitted to read from the Book of Nature? If this contradiction were possible, then God would be proved to be a Being absolutely less trustworthy than many of His creatures."

Dr. Meadows then examined the opposite views held as to the nature of Life; expressing himself in favour of the doctrine that it is distinct and separate from ordinary physical forces. This view was, he thought, "greatly strengthened by the consideration of what takes place in an organic body when, as we say, life has fled. Then at once the physical forces, such as chemical action, which have been kept in check, if not by the vital force, at least during vital action, exercise an undisputed sway over the now dead body; and the result is that its component parts gradually but surely lose all trace of structural character, and are resolved into their ultimate chemical constituents: construction is at an end; destruction is rampant, and no power suffices to avert the catastrophe." With reference to the bearing of the question of the nature of life on medicine, he said:

"Our whole course of study, dealing as it necessarily does with material objects, not only in physiology, but also in pathology and therapeutics, is apt to engender a too materialistic view of disease, and to obscure our view of the morbid processes by which disease is brought about, processes which are essentially deviations from the normal evolution of the life-force, whatever the nature of that force may be. It is so much easier to recognise the effects of what we call disease, the mind comprehends so much more readily what the eye sees, and the hand can touch, that we are almost inevitably drawn to the recognition of the organic lesion as the alone cause of the patient's distress, and as the object towards which our remedial efforts should be directed. But it is certain that, if we inquire into the matter, we shall find in most cases evidence of what is called functional, or as I would term it, dynamical derangement, long before the existence of organic lesion, and a little thought will suffice to convince us that functional derangement is but another term for the abnormal operation of life-force. For, as the force or dynamical agency which is inherent in the life-germ secures the normal growth and development of the body of which it is the germ, so deviations from that force necessarily lead to abnormal tissue change; in other words, to disease, either during growth and development, or in subsequent maturity.

"Here, then, we see the importance of studying the laws which regulate the operation of that force, and their effects upon the bodily structure. By observing these actions during health, we may in time hope to

gain some clearer conception of the causes of disease—those causes which are at present enveloped in so much obscurity that we can hardly be said really to know the *modus operandi* of any one of them. It is through the subtle workings of the life-force that minute tissue-changes are produced; and it is here, therefore, that we must look for the earliest indications of the coming disease. When the grosser manifestations of organic lesion are apparent, it is then too late to trace out the ultimate cause of the evil; and that which, if it could have been recognised and appreciated in its earliest stage, might, perhaps, have been combated successfully by a very simple remedy, now baffles and defeats all our efforts. Recent observations have shown how, by the thermometer, timely warnings of impending mischief are often given long before any other indications are apparent. It is in this direction that we must look for future advance in medicine, and each one of you may, if you will, be of infinite service in this work. There is yet an abundant harvest for the honest, painstaking, humble labourer in the medical vineyard."

In concluding, the lecturer urged his hearers to remember that the one object of their lives should be to seek after and to maintain truth. They must practise truth persistently, not only in their profession, but in every minute particular of their daily life.

#### KING'S COLLEGE.

THE Introductory Address was delivered by Dr. RUTHERFORD, Professor of Physiology.

After stating that the chief objects sought for by those who profess medicine are to preserve health and cure disease, Dr. Rutherford pointed out that a knowledge of the healthy state and of the conditions necessary for its preservation, must necessarily precede a knowledge of the diseased state and the means required to rescue an individual from it. After referring to some of the attractive features of biological science, he stated that, although medical studies deal to some extent with metaphysics, they nevertheless chiefly concern the two great factors of the physical world—to wit, matter and energy. "The first great idea which those who enter upon the study of living beings should lay hold of is, that the matter and energy which are found in them are derived from the dead world around them. Things that live, although they can transform matter and energy in the most marvellous ways, can neither create nor destroy them. A continual stream of matter and energy flows from the dead into the living world, serves its time there, and returns to the dead world. . . . Seeing that the matter and energy found in the organic come from the inorganic world, it might be anticipated that the changes through which they pass in the world of life are subject to the same laws which govern them in the world that is lifeless. Such appears to be the case. The law that rules the chemical changes taking place in a muscle does not differ from that which regulates the chemical changes that go on in a steam-engine. The laws that preside over the movements of the blood are just those which control the movement of any other liquid. The metamorphoses which matter and energy undergo in the living world are many of them infinitely more complex and difficult to follow than those through which they pass in the inorganic world. It is therefore necessary that one should be acquainted with the character of the phenomena found in the inorganic ere we attempt to follow or comprehend the more intricate nature of those found in the organic kingdom. In short, the chemistry and physics which immediately concern lifeless things must be studied before the chemistry and physics which immediately apply to things that live can be comprehended. In other words, a knowledge of inorganic chemistry and physics must be acquired before organic chemistry and physics can be understood."

He then, with the aid of some familiar illustrations, explained the methods of observation and experimentation by which facts in natural science are ascertained, and pointed out the disastrous results that follow hasty observation, careless experimentation, too rapid digestion of facts, and the substitution of fiction for truth. The truly scientific method of investigating the events of life was begun three-and-twenty centuries ago by Hippocrates, and fortunate would it have been had the path which he opened up been pursued; but the dark ages enveloped it in obscurity, and it was not fairly reopened until our immortal countryman Harvey found his way into it, and Bacon shed the light of his genius upon it.

In indicating the present position of medicine, the lecturer stated that in inquiries regarding living things in a state of health or disease students should particularly attend to—1. Their physical or structural composition. 2. Their chemical composition. 3. The functions or actions which they perform. He stated that the four great essential subjects in medicine are physiology, pathology, hygiene, and thera-

peutics, and proceeded to explain what was meant by these subjects, and to give an account of their present position. "The most advanced part of physiology and pathology is that which refers to the structural composition of the body. Our knowledge of the chemical composition of the body is not so advanced, because of the excessively difficult nature of the inquiry. Very much has been learned regarding the actions of the body in health and disease; but, although we know a great deal regarding these actions, we are far from having ascertained all about them. No stone, however, is being left unturned. The secrets are being sought out with the aid of the most refined physico-chemical instruments and processes.

"The causes that give rise to the phenomena of life have, ever since the first glimmerings of science, formed a deeply engrossing subject for inquiry; and assuredly, as time runs on, the interest and importance that attach to such a question, far from diminishing, continue if possible to increase. For centuries there has been a keen controversy between the vitalists and physicists. The vitalists first took up the ground, and ascribed the operations of the body to spirits—good during health, and evil during disease. Hippocrates, three-and-twenty centuries ago, started the hypothesis that the actions of the body are presided over and directed by a spirit termed Nature. Aristotle called this spirit Vegetable Soul; and said that it is common to all plants and animals. In modern times this spirit, or principle, has received various names, and its existence is still believed in by some physiologists. By them it is looked upon as directing the various operations necessary for the life of plants and animals. In opposition to this idea, many physiologists have come to the conclusion that the existence of such a spirit is a myth; and they believe that the ordinary vital operations of plants and animals are due to the ordinary attributes of matter and energy. There has been some extravagance on both sides. Some vitalists have called the holders of the physical view materialists, even if they refuse to believe that a cabbage is possessed of a vegetative soul; alleging that if we deny the existence of such a soul in a cabbage, we must deny the existence of man's rational soul, and even the existence of a God. On the other hand, some upholders of the physico-chemical views have absurdly maintained that the properties of matter and energy may be regarded as sufficient to explain all mental phenomena. The controversy is still unsettled."

In alluding to the spiritualists of the present day, the lecturer said: "We have been informed by a noble lord that a certain Mr. Home is able to defy the law of gravitation to an extent which is, to say the least, very remarkable; we have been seriously told that he can fly through the air by a mere effort of his will. The number of those who possess this marvellous power would seem to be very limited; and it is fortunate for cab-proprietors and railway shareholders that the number is likely to remain a small one. As yet Mr. Home and his disciples do not seem disposed to make a public exhibition of their marvellous powers. Probably they still continue to ride in omnibuses, cabs, and railway carriages, and find it safer to trust themselves to such modes of conveyance rather than to their newly discovered method of aerial flight. Spiritualism of the sort now fashionable is not so very novel as the spiritualistic media would fain have us believe. Within the memory of most people, miracle-workers have been ever and again starting up. The tricks of the mesmerists, spirit-rappers, and table-turners made dupes of a great many simple-minded persons. Possibly the media have now become so dexterous, that they can make dupes of persons whose minds cannot be exactly charged with simplicity; but, nevertheless, it is probable that ere long their tricks will be exposed, just as all similar tricks have been."

Hygiene, the lecturer said, is in a state of considerable advancement. We know well the ordinary conditions necessary for preserving health; but we have yet much to learn regarding measures sufficient to protect man from the malignant agencies that produce disease. Nevertheless, the great success of vaccination leads us to expect great achievements in this direction.

He explained many of the reasons why therapeutics are in a state which, though rapidly improving, is still far from being satisfactory. "The mechanical appliances adopted by the surgeon are, on the whole, eminently satisfactory. Nothing can surpass the cunning and dexterity with which he uses his knife to remove a diseased member. Still, in the majority of cases, the use of the knife in disease implies the confession that the surgeon has failed to arrest the diseased condition of the part. Both surgeons and physicians experience extreme difficulty in exercising a really curative influence over disease. Petronius Arbitrator was wrong, however, when he said that 'a physician is nothing but a satisfaction to the mind'. Happily there are many diseases which can be completely cured, and a great many more that can be influenced for good, by the use of remedial measures; but still the achievements of medical men are circumscribed by a circle which, though ever widening,

is yet a narrow one. The chief reasons for this limited success are, that we are still unacquainted with many of the healthy actions that take place in the body. The causes of many diseases are as yet unknown. It is not yet possible to ascertain precisely what parts of the body are affected by some diseases. Obscurity still hangs over the significance of many of the altered bodily actions that are observed in disease. Some of these actions have a fatal, others have a beneficial, tendency; and the difficulty is to know which to favour and which to repress. The actions of many drugs, and other remedial agents, are only partially known; and even where these actions have been ascertained, there remains the difficulty that the precise influence of the drug differs in different individuals, and even in the same individual at different periods of his life. But we are not possessed of the power of ascertaining beforehand what are all the respects in which one man differs from another, and therefore we are not by any means always able to predict what will be the precise influence of the remedial measures which we adopt: hence it is that medicine does not present the characters of an exact science. We cannot, in many instances, say what is or what will be, nor can we always with precision wield those powers which we already possess for influencing the constitution of the body and its actions. We have, for the present, to weigh probabilities, and to hit the mark as nearly as we can. This fact need not, however, dismay those who are entering upon the study of medicine. She is daily becoming more exact; and the pleasure and satisfaction which result from an honest and earnest attempt to render her more scientific quite outweigh any disappointment one may be inclined to feel at finding that she lacks much of that precision which gives such charm to physics, chemistry, and mathematics. The great fact to be remembered is, that medicine must be pursued in a scientific spirit. Only by cautiously comparing and weighing all the facts of any case, and coming to just conclusions from these, can we hope to advance medicine. We have to bear in mind that whenever we give a man a dose of medicine we really perform an experiment—an experiment which is important to the person and important to the science of medicine. . . . Observe all the conditions of the experiment, and write them in a book, so that they may never be forgotten by your memories, which are treacherous at the best. Old Hippocrates showed us a splendid example. He wisely saw that to get at accurate facts is the backbone of all science. He did not content himself with remembering his facts; he wrote them on tablets, so that they might never be forgotten or altered."

The lecturer said: "A great and attractive feature connected with the prosecution of medicine is the open-handedness that everywhere prevails with regard to discoveries. The moment a medical man makes a discovery, however valuable, he tells it to all the world, so that every one may have the advantage of any good contained in it. In consequence of this absence of secrecy, it is in the power of every one to acquaint himself with and to adopt any measure that is proposed for the treatment of disease. Nevertheless, although there is free intercourse between medical men in every part of the world, medical science presents somewhat different aspects in different countries. Diseases which are rare in this are sometimes common in other lands. The type of disease which may be rare here may prevail elsewhere. The mode of treating some diseases differs in different schools. The methods adopted in the tuition of medicine are not everywhere the same. It often happens that certain schools are famed for the facilities with which certain subjects can be studied: for example, although the surgery in England is in many respects decidedly superior to the surgery of France, nevertheless students have greater facilities for the practice of operative surgery in France than they have in England. Although physiology and pathology are in many respects just as advanced in England as they are in Germany, nevertheless many inquiries connected with these subjects can be prosecuted in Germany with less expense and greater facility than in this country; for in Germany the Imperial powers liberally support physiological and pathological laboratories, and happily in that country physiologists and pathologists are not pursued by a herd of anonymous scribblers, who, while they wink at all manner of sports, however cruel and meaningless, are ready to thrust their waspish stings into any one who dares to decapitate a frog in the interests of the healing art. Seeing that the aspects of medicine are not anywhere alike, it is very important that you should visit different schools of medicine in order to get an education as comprehensive as possible. It is well to visit the chief schools of France and Germany. The Germans and the French have much to learn from us, but at the same time we have not a little to learn from them."

The lecturer concluded with some practical remarks concerning the mode of study which should be adopted by the students.

## WESTMINSTER HOSPITAL.

THE Introductory Lecture was delivered by Dr. BASHAM, physician to the Hospital. He commenced by observing that it might be to the advantage of those now entering the profession to have placed before them the relative position assigned to medicine and surgery among the other arts and sciences. These words were so constantly employed almost as convertible terms, that it was expedient to give such a definition as would enable the student to comprehend clearly the position held by medicine among other branches of human inquiry. The word science comprehended investigations into the powers and properties of matter, inorganic as well as organic; the mutual action of forces and masses; the laws of matter, statical and dynamical. The term art was applied to everything which was the product of the mental or manual skill of the individual. Science, properly so called, was either deductive or inductive. The first comprised the exact sciences—mathematics. The second, inductive, included the natural sciences, or physics; and the object of these was a knowledge of the laws of the material world. The natural sciences were then classified, and the necessity for a knowledge of them to the student and practitioner of medicine was insisted on. It was shown that all these branches of knowledge rested on a correct and trained observation. The arts were then enumerated. They severally included whatever was effected or produced by the mental conception or the manual skill, or both, of individual minds, art producing combinations or effects which could not happen or exist except through the conceptions of individual intelligence. The highest efforts or products of art might be accomplished without any specific knowledge of natural science. But when art was aided by natural science, the result was greater perfection. But if science was not absolutely necessary to the existence of art, very different was it with the practice of medicine. There was not one of the natural sciences, some knowledge of which was not imperatively required in medicine. The aim and scope of medicine as an art was the preservation of the body in health, and the freeing it from those evils and disorders which neglect of the laws which govern and minister to life most surely entailed. These could only be accomplished by a thorough knowledge of the nature and force of those laws. The first essential was a minute and searching knowledge of structure, both human and comparative; the second, a knowledge of the functions of the several organs. On a thorough knowledge of anatomy and physiology the whole fabric of medicine rested. The vital forces were examples of the economy of the natural laws of the material world. Not only did these vital forces work in accordance with the physical laws, but they were evolved in strict obedience to, and dependence on, those laws. The functions of the heart, of the lungs, the action of the muscles, the structure of the eye and ear, were illustrations of the adaptability of structure and function to the laws of the natural world. The position of medicine up to this point was that of a science strictly inductive.

After an allusion to the causes of disturbed function and the relation of medicine to the study of epidemic disease, the lecturer proceeded to sum up the attributes of medicine both as a science and an art. It was a science in relation to the means and sources from whence it was derived, for it was built up of many, if not all, of the other natural sciences. It was an art, however, in its exercise; and its value was proportioned to the scientific training, the tact, and judgment, of the individual practising it. It was an art which, for extent and variety of knowledge possessed by its more distinguished members, was not exceeded, scarcely equalled, by any. Its utility was universal, for it was with advantage and benefit exercised in every region of the world, alike useful to all nations, peoples, or creeds. Medicine was the science of observation applied to the investigation of everything which related to the health of man, individually or socially. It was based on a thorough knowledge of the structure of man and of the chief families of the animal and vegetable world, to which must be added a knowledge of the laws pertaining to matter and force. To be educated in such an art, brought to the possession of all the advantages and graces of an enlightened education. It trained the mind to understand the laws regulating the evolution of the germ out of which his organisation sprang. It taught him the conditions governing nutrition, regulating development, or ministering to decay, the premature tendency to which it was the effort of the art to avert. As an art, it dealt in no dogmas; it regarded, as reliable and true, only that which was susceptible of demonstration and proof. It sought no converts, for the essence of its teaching was, that its followers must be for ever students; for the words of Harvey were ardently accepted by all workers, "that all we know is infinitely less than all that remains still to be known". In this art there was no fealty sworn to authority; and that which was moment held its ground only so far as experience or science proved it to be true. The sciences on which this art rested could not be learnt from books alone. The fabric

of Nature and of the material world must be searched and studied, and each step must be steadily made from one demonstrated fact to another. The theories of incomplete observation were constantly tested by more numerous and reliable facts, and scientific experiment eventually verified or ignored them. Thus gathering within herself the tributary streams of many branches of natural science, each contributing some truth or fact applicable to the interpretation of the laws of health and disease, medicine might consistently take her place among the arts and sciences, and claim a prominent position among the most useful and beneficent of those scientific pursuits to which the intellect of man might be devoted.

## CHARING CROSS HOSPITAL.

DR. GREEN delivered the Introductory Address.

The lecturer, in the first place, alluded to the irreparable loss which the hospital and medical school had sustained in the death of the late Dr. Hyde Salter. He then proceeded to review the improvements which, during the past year, had been made in the hospital and school premises—the new wards and the increase in the number of beds, the new dissecting-room, library, *post mortem* room, and physiological laboratory; and the valuable additions which had been made to the staff. In seeking for a special subject upon which to address his audience at the commencement of another medical session, Dr. Green said that that which appeared to him to be the most deserving of attention was the necessity which exists at the present time for a more *practical* study of medicine and surgery. The time was gone by when a few hours spent in the lecture and dissecting-room, and the commission to memory of a small volume of multifarious facts, was all that was required of the medical student. The medical profession was essentially a practical one, and medicine, no less than surgery, demanded a practical education. The lecturer then proceeded:—

"It has been argued, and students have left their medical schools with the impression, that a practical knowledge of our profession is easily to be acquired after going into practice—that the engagement in the attempt to treat disease brings with it the knowledge which it is necessary to possess. I do assure you, gentlemen, that nothing can be more erroneous. I do not mean to deny that an educated student, a man well-grounded in what we may call the elements of medicine and surgery, may and does derive very much additional knowledge from the practice of his profession. On the contrary, an educated man engaged in practice is in the most favourable position for acquiring an increasing store of knowledge. He starts upon a firm basis, and one upon which he can, year by year, continuously and successfully build. But I do maintain that, if a man upon leaving his hospital studies do not possess a large amount of practical knowledge—knowledge, remember, which can only be obtained by systematic work in the wards and in the out-patient room—the chances are very much against his acquiring this knowledge after he has once commenced to practise. If he do not acquire such essential elementary accomplishments, for example, as how to put up a fracture, how to palpate the abdomen, how to distinguish between the systolic and diastolic cardiac sounds, or how to recognise urinary deposits under the microscope whilst he is a student, the probabilities are that he will never do so at all. It is to prevent the possibility of the student finding himself in such an unenviable condition that the examining boards have recently made these changes in the curriculum and in the character of the examination; and it is in order to stimulate you to do your best to prepare yourselves for all that will be required of you, that I have ventured to bring this subject before you on the present occasion."

After alluding briefly to the nature of examinations, Dr. Green continued:—

"Be assured then, gentlemen, that which will be required of you is such a knowledge of your profession as is not to be obtained from the attendance upon lectures or from a perusal of books, but can be acquired only by the *practical* study of disease. This will be required of you not only by your examiners, but also by the public. The time, we believe, is rapidly passing away when mere professional tact will suffice to ensure success in the practice of our profession. Tact must always be an important element in the acquirement of success, but, as education advances, and as medicine and surgery continue to approach that high position which they justly deserve, we shall find that there is an increasing demand for real knowledge, and that tact without this will no longer be accepted."

In order to obtain this knowledge, the lecturer impressed upon the students the necessity of availing themselves of all those opportunities which, in consequence of the regulations passed by the examining boards, were presented to them. They should hold clerkships and dresserships with the determination to acquire from them all the practical know-

ledge which the filling of such offices is eminently calculated to convey; the various means provided for practical instruction should be utilised; and these should no longer be regarded as optional, but as necessary parts of education. He then pointed out the importance of students studying disease for themselves, and said:—

"If I mistake not, the knowledge we derive from even one half-hour devoted to the careful and painstaking study of a single patient will be more valuable to us than many hours spent in listening to the teaching of others. It is this kind of clinical work which appears to us to be the great want in our education at the present day. We do not, I think, sufficiently recognise its importance, and hence, except in the case of those comparatively few students who are fortunate enough to secure resident hospital appointments, and of some of the more studious clerks and dressers, it is almost unknown. We do not mind going round the wards or into the out-patient room, and listening to the clinical remarks of our teachers; but we do not consider it at all necessary to examine the patients for ourselves, and even if we are asked to do so, we perhaps hardly take the trouble to do it in anything like a thorough manner. And yet, surely, it is from such study as this that we are most likely to derive that practical knowledge which we shall stand in need of when we are thrown upon our own resources. How many hours of our student life do we spend in the dissecting-room studying the dead body? Ought we not to spend a more proportionate amount of time in the wards studying the living body?"

The lecturer then remarked upon the insufficiency in the amount of time set apart in the curriculum for systematic clinical work, and continued:—

"Examine the patients for yourselves. Form your own conclusions as to the nature of their diseases. Decide upon the plan of treatment you would adopt, and make your own prognosis. And, by all means, be very thorough in what you do. Spare no pains and grudge no time in learning all that you possibly can of the case you are observing. Remember that more mistakes are made from want of care than from want of knowledge. Do not attempt to observe too many cases at a time. One done well is far better than a dozen done incompletely. Watch the same case carefully from day to day. Note the natural course of the disease, and the way in which it is influenced by remedies, and if it should terminate fatally, let nothing prevent your being present at the *post mortem* examination."

The lecturer concluded by an allusion to the rapid advances which are being made in the knowledge of pathology and therapeutics, and by an exhortation to the students to use all diligence to acquire during their student life what in the present age would be required at their hands.

#### LONDON HOSPITAL.

DR. LITTLE, formerly physician to the Hospital, delivered the Introductory Lecture. He was tempted, he said, to look back to the time—forty-three years ago—when he for the first time sat on the benches of the old anatomical theatre, listening to the introductory lecture of Mr. Headington. Of those who were his fellow-students, one at least—Mr. Curling—"by his persistent exertions in the cause of practical and scientific surgery, his researches in pathology, by his readiness to adopt all novelties that promise to be beneficial to humanity, has shown the present generation of students how the advantages of the London Hospital can best be utilised. He can recall, we doubt not, the glories of the discoveries and improvements of the previous forty years, as related to us in language unsurpassed for accuracy and for freedom from exaggeration—in language pure in diction, noted for clearness, quietness, and perspicuity." Mr. Headington, the lecturer remarked, "was an accomplished and sound surgeon, who had more the appearance of the learned and well-bred physician of that day. He early handed over the operating knife to the able hands of Mr. Luke, then his assistant-surgeon. The greater number of my hearers", said Dr. Little, "may never have heard the name of Headington: in fact, he lived, he practised, and died, in a part of London—Spitalfields—then wealthy and of comparatively fashionable resort. It has been a loss to surgery that he was not addicted to spreading his fame by any writings; but it is a sufficient proof of the distinguished hold he possessed on the respect and affection of his colleagues and pupils, that he was one of the few whose busts and portraits adorn the building in which we are now assembled." Mr. Headington was accustomed to make known to his pupils the labours of the men to whom the advances in medicine of the previous forty years were due; and Dr. Little occupied a large portion of his address in taking a brief retrospective view of the leading characters referred to—e.g., John Hunter, Jenner, Davy, Black, Priestley, Dalton, Cuvier, Bichat, Brown, Broussais, Dupuytren, Larrey, Cline,

Cooper, and others. The lecturer then noticed the changes which have taken place in medicine during the last forty years. Each of the two periods to which he referred was preceded by great changes in the world at large. The beginning of the first of these periods might be regarded as having been ushered in by the American War of Independence and the great French Revolution. "The consequent agitation of men's minds, as well as the acquisition of a new power supplementary to man's individual physical force, in the application of steam to the purposes of mankind in branches of the arts into which it had not been previously introduced, were probably all momenta aiding the progress of man in the departments of science and learning embraced by the cultivator of medicine. In this country eminent medical men worked on in our thoroughly English way, little aided by state assistance, except in the happy circumstance of the purchase by Government of Hunter's museum. Hunter's fame needed not even the preservation of his museum to render it *are perennius*. It cannot be doubted that Hunter's career exercised considerable influence on the progress both of English and foreign medicine during the first thirty years of this century. But in France in particular, at the beginning of the present century, a great impulse was given to medical studies by the appointment of a government commission on the reorganisation of the medical schools of Paris, Montpellier, and Strasburg. The names of many of the ablest physicians and philosophers of that country appeared upon that commission. In Germany, also, the younger University of Berlin, fostered by the wide confidence in the future of German science, was beginning to emulate the reputation of Leyden, Göttingen, Upsal, Halle, and Vienna." Speaking of the forty years now past, Dr. Little said: "Possibly we may be disposed to regard the cautions necessary in mistaking the *propter* for the *post*; but it appears, nevertheless, true that the last forty years, like the former period of similar duration, was ushered in by stirring changes in the world at large. One of these was the reform movement about 1830, of which certainly one consequence has been that of a greater attention to, and diffusion of, education—a direct result of the accelerated movement of ideas of that exciting period, and a great extension of periodical and higher class of literature within and without our profession. During this period the application of steam to land-travel, and especially to transatlantic and other distant maritime locomotion, followed, as it soon has been, by electric telegraphy, have all contributed to bring peoples of different countries to mutual intercommunication of ideas, opinions, and discoveries, and have stimulated improvement in our art during the last forty years, equally with other arts, professions, and pursuits."

Dr. Little remarked that anyone whose memory could carry him back to the state of medical affairs in 1830 would agree that whatever influence was exercised upon English medicine from abroad was mainly derived from the schools of Holland, Italy, and France. By far the greater part of that which came to us from the Continent proceeded from French sources. This was particularly the case during the fifteen years following the peace of 1815, which opened Paris to our predecessors, with the treasures accumulated by Dupuytren, Larrey, Corvisart, Laennec, and a host of other distinguished men. Since 1830 the most superficial student of medicine could not fail to have noticed the influence of German anatomical, physiological, and pathological discoveries, as well as of practical medical and surgical improvements, upon English medicine.

Having noticed some of the improvements effected since 1830—such as the introduction of tenotomy and lithotripsy, the researches of Bright on disease of the kidneys and of Addison on that of the spleen, the employment of auscultation, percussion, and thermometry, the discoveries in diseases of the nervous system and in syphilis, the lecturer referred to the prospects of medicine during the coming forty years. Among the departments of medical practice still requiring earnest study, he specially referred to the prevention of disease, and the successful treatment of such diseases as *algide cholera*, hydrophobia, and advanced consumption. "Are we too sanguine," he said, "when we express a hope that before another forty years shall have elapsed some of the diseases last named shall have become more tractable to our art?"

In giving some concluding advice to the students as to the manner in which they should endeavour to profit by the instruction afforded in the hospital, Dr. Little said: "Never be content with superficial observation; whatever you undertake to inquire into, look below the surface of things, employ all your senses in your investigations, avail yourselves of all the modes of inquiry taught you. In the present day it is useless to be merely a good auscultator, well up in the chemistry of the urine, familiar with the names and varieties of the excretions, skilful at anatomy and the setting of fractures; you must apply *thoroughly* all your ability. In fact, the English word *thorough* should be your watchword and guide in all your doings. Your first duty is so to profit by the instruction here provided that you may make capable members of

an active, honourable, and useful profession. . . Schiller says of Science and her followers—

“Einem ist sie die hohe, die himmlische Göttin, dem andern  
Eine tüchtige Kuh, die ihn mit Butter versorgt.”

“Let it be your resolve, whilst seeking an honourable existence through your profession, to cultivate it more in the spirit of the first of these lines than in that of the second. This alone can make you satisfied with it.”

### THE MIDDLESEX HOSPITAL.

DR. JOHN MURRAY delivered the Inaugural Address. The lecturer commenced by urging the new students of medicine to inquire of themselves whether they were adopting a profession for which they were naturally fitted. According to the comparative vivacity and force of a young man's intellect, his fitness for a profession should be gauged. If a youth afforded no evidence of predominant interest in literary study and the delights of scholastic ambition, he ought not to be encouraged to adopt a profession requiring that considerable amount of application to such pursuits demanded by medicine. He referred to the unhappy instances daily to be seen, of men possessed of excellent abilities engaged in the half-hearted pursuit of occupations wholly unsuited to their natural turn of mind—abilities which, if they had been directed into the proper channels, would have placed the possessors in positions in which they would not only have excelled, but would have increased their enjoyment of life—perhaps also the depths of their pockets, and certainly their value to the public. Most young men's minds, he believed, afforded a clue, if properly scrutinised, to their natural fitness, to ascertain which was the duty of parents and guardians; and this was becoming daily more and more imperative as free trade, the correlative of natural selection, was, in this country at least, in the ascendant. To make the most of this natural fitness, the preliminary education of the young man should be of a most liberal character. The great acuteness in the observation and treatment of disease displayed by men of the present day distinguished in medicine does not, he believed, rest on the possession of medical facts alone, but on a sound general education, aided by natural ability for the practice of their profession. He decried the growing tendency amongst the advocates of the real or modern or so-called useful studies to underrate the value of classics, by the study of which we are made acquainted with the spirit and power of Greek and Roman antiquity, learned from its original works. A liberal education should make a man know himself and the world, not in a narrow sense, as Matthew Arnold expresses it, “to make a man a good citizen, or a good Christian, or a gentleman, or to fit himself to get on in the world, or to enable him to do his duty in that state of life to which he is called. There is a wider and a more noble sphere—to do good to mankind, and to advance his fellow-creatures.”

After offering a few words of advice as to the manner in which the student of medicine should proceed in surmounting the mass of work before him, Dr. Murray continued: “To assist and guide the student in his studies, medical schools have been formed, in which more or less compulsory attendance is required; the different subjects taught being arranged in such a manner as to afford a very considerable amount of assistance to the pupil. Our metropolitan system of medical schools, as it at present exists, has found many able opponents, men whose opinions carry with them great authority, and in whose views I am prepared largely to sympathise. But, while we should sanguinely look forward to a future still greater than the present in the medical education of the metropolis, there still can be no doubt that even now, with its disadvantages, London affords many unrivalled opportunities for the study of medicine unattainable elsewhere.

“The mission of a medical school, it seems to me, should be not alone to cram the student with facts, but to effect as far as possible his total education in his strictly medical studies. What is to be avoided is, the degeneration of the instruction into a preparation for examination, instead of providing that the pupil may have the requisite time to come steadily and without hurrying to the fulness of the measure of his powers and character; that he may be securely and thoroughly formed, instead of being bewildered and oppressed by a mass of information hastily heaped together. Do the medical schools of London effect this? That there is much room for improvement in their teaching, that the tutorial system might be with advantage grafted more largely into them, less stress laid upon certain subjects, and other compulsory courses instituted, I am very strongly of opinion; but that they do much to develop general medical education, I most certainly assert. If this desirable object be not attained, it is not entirely the fault of the schools. What faults they do possess are in a great measure due to the baneful influences of certain of our licensing bodies, which do not demand a sufficiently high standard for qualification, and do not

allow the schools time to develop the student. That systematic teaching is, as asserted, carried to an excess in them I do not believe; in fact, the very reverse. That students should be allowed to study whosoever and howsoever they please, as recommended by not a few, is a doctrine which I think should be resisted as opposed to reason, and a retrograde step in education. Were it possible, as is proposed, to render the examinations all-sufficient as tests, which I deny they can be made to be, the more or less want of system in the preparation for these examinations would entail a waste of time and strength, and by reaction, tend to reduce the standard of examinations. It is this absence of system which, I believe, is the bane of education in this country. In everything we lean upon our energy and wealth to overcome the drawbacks necessarily dependent on our want of gradual training and method. We forget that, ‘if the iron be blunt and a man do not whet the edge, then must he put forth the more strength: but wisdom is profitable to direct.’

“How are students, I would ask, to be guided in their studies unless in a systematic school? where are they to learn exact habits of mind? Not in books, certainly. They must be brought to the water and taught systematically and gradually how to drink. But they must be compelled to do so; and I believe in spite of all that has been said to the contrary, this can be done if properly tried. Most students are willing and anxious to learn if intelligently managed; and if the teacher fail, it is, in the majority of cases, as much the fault of the teacher as of the pupil. If there be those indisposed to apply themselves to their work, much can yet be done to make them learn by methodical and compulsory teaching. Were it not for our compulsory system, however, what would become of students? One would stay at home and cram; another would go Will-o'-Wisp from place to place, ‘taking tithe of mint and anise and cummin,’ but neglecting the principles and more important matters of his profession, picking up crumbs which he would mould together into some crude idea representing his peculiar notions of the theory and practice of medicine; while only a comparatively small number, chiefly through their inherent natural good qualities, possessed of a comprehensive medical education, would pass their examinations. A considerable number would probably be able to pass the examinations, however strict and searching they might be; but their minds would not have been gradually formed, and taught that exactness of reasoning which is likely to be engendered by a proper system of teaching, such as is aimed at in some at least of our medical schools. I would have you, therefore, to bear in mind that system and regularity in your work are all-important.”

The remaining portions of Dr. Murray's address were chiefly directed to detailed advice in reading, in attending lectures, and in clinical work—in the last of which he pointed out that our metropolitan system is deficient. He earnestly urged upon students the desirability of going abroad for a time, and extending their term of student-work beyond that required by the licensing corporations, and advised them to obtain the highest qualifications possible; and alluded to the shameful state of ignorance in which some young men commence practice, possessed though they be of one or more British qualifications.

The lecturer concluded his address by reminding his hearers that beneficence formed medicine's highest title to respect; that their duty, their real pleasure, would be found in allaying misery, in assuaging suffering, and advancing the physical and moral well-being of man. He pointed out that *succurrere miseris* was the first lesson of their profession; and in carrying out their great and noble object they should do it as best as they could.

### QUEEN'S COLLEGE, BIRMINGHAM.

THE Introductory Lecture was delivered by Dr. JAMES RUSSELL, Professor of Medicine.

He commenced by quoting the introductory remarks with which Burton opens the chapter on the cure of “Melancholy,” because, as he observed, they present a more correct representation of the function of the medical practitioner than that which generally obtains. In place of imposing the entire responsibility in treating disease upon the medical adviser, leaving the patient to digest the medicine and swallow the advice he receives without co-operation on his own part, the author regards the patient as an active agent in effecting his own cure, and reminds him that, if the doctor has a duty to perform towards him, he has also a duty which he owes the doctor. Dr. Russell was thus led to dwell upon the two-sided character presented by the medical profession, its relation to medicine as a science, and its relation to the society in which the science is to be applied. The lecturer commented on the influence which public thought has exerted over the interests of the medical profession viewed merely in its scientific relation; noticing how

universally medical opinion has been the reflection of the opinion of the age in which it has been formed. In one particular, however, he believed that medical science stood in contrast to the philosophy by which it was surrounded, at least in the earlier periods of its history. If Macaulay has rightly stated, as the characteristic element of the ancient philosophy, that "it disdained to be useful, and was content to be stationary," that it "could not condescend to the humble office of ministering to the comfort of human beings," then medicine must claim to have had a higher aim throughout its various fortunes, that aim being "the multiplying of human enjoyment, and the mitigating of human suffering."

Dr. Russell observed that the evils with which medical science has had to deal have been in no small measure the product of human passion, and in a still greater measure have resulted from ignorance of those laws which have been imposed by Providence as necessary conditions for the preservation of health; and he noticed that the success, or want of success, which has attended the efforts made for the removal of such evils, has depended in no small measure upon the degree of intelligence with which the subject has been regarded by the public at large. This statement may be applied to disease in all its forms, but it is illustrated on a large scale by the history of nations. He glanced at the pestilences which form so prominent a feature in past ages, preceded in almost every instance by famine, the consequence sometimes of bad seasons, but rendered fatal in their results through ignorance of agriculture, through defective legislation, and through want of free intercourse between different districts; but far more frequently the consequence of civil and foreign war and of political disturbance. He then passed to other causes of public disease connected with social or private life, as exemplified by the mode of living prevalent in the middle ages, by the condition of the land, by the state of our prisons as revealed by Howard, of our ships and hospitals as disclosed by Lind, Blane, and Pringle. In the present time, sanitary inquiry is announcing the presence of evils of precisely the same kind, and is tracing up to these evils precisely the same effects. It is of vast moment to the interests of humanity that both the profession and the public should understand their part in the responsibility to be borne. An enlightened public must be the correlative of an educated scientific body, or nothing can be done.

The medical profession is in the position of having to study science with reference to its immediate application; and the aspect in which the subject presents itself to the minds of medical men is not that of abstract truth, but of truth valuable in proportion as it can be made available for the benefit of mankind. Their discussions, therefore, must be influenced by a consciousness of the momentous nature of the interests involved, and by the knowledge that the main responsibility rests upon their own shoulders. On this account it is natural and proper that medical men should throw their whole heart into the controversy. Thus it has happened that the relation held by the public towards the advocate of medical truth has not always been consistent; sometimes he is credited with possessing precise knowledge, such as can belong to the student of physical science only; at others he is regarded with absolute scepticism because he does not, like Molière's *M. Purgon*, "believe in his set rules more than in all the demonstrations of mathematics, finding in medicine nothing uncertain, nothing difficult."

The language of the student of medicine will be modest in exact proportion as he has obtained a better acquaintance with his subject and a larger view of its several relations. Yet he is no stranger to the tone of authority when circumstances justify its assumption. He knows that the conditions with which he deals are regulated by fixed laws; and where such laws have been clearly eliminated he announces them with all the authority of ascertained truth. And in the operation of these same laws he recognises a limitation placed upon his own power. He knows that it is as impossible for his science to avert the effects of sensuality upon the bodily functions, as for the ethical philosopher to prevent its exerting its baneful influence upon the mind. Nor can medical science be expected to shield a community from the consequences of violating the conditions imposed by Providence for the preservation of health. Poul drains will generate fever, let science say what it will; overtaxed brains will fail; overstrained muscles will ache. But if, in a large part of her utterances, medical science wisely uses a less dogmatic tone, it is because the interests with which she concerns herself are closely interwoven with those moral and physical conditions which constitute the discipline of life, and determine a man's moral position in the world. Hence, doubtless, the reason that many of the problems of health and disease appeal to men as free agents, and call upon them to assume a share of responsibility in the use which they make of the knowledge afforded to them.

The lecturer concluded with some remarks addressed specially to the students of the College.

#### UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE.

THE Address was delivered by Dr. G. H. PHILIPSON, M.A., and was devoted to the subject of medical education. The aphorism of Paley, that "education, in the most extensive sense of the word, may comprehend every preparation that is made in our youth for the sequel of our lives," was commended as the lesson to be inculcated at the inauguration of a new session of medical study. To some it might appear commonplace; but there was one way of giving it freshness and importance, by reflecting on it, in direct reference to our own state and conduct, to our own past and future being. The mind of the boy was contrasted with that of the youth about to pass into the man; also the education of the school with that of the college; an important difference being, that the serviceable routine, the fundamental and obligatory teaching of the school, gave place to the more varied and more self-imposed duties of the college. The mind, in just proportion to its progress, was allowed liberty of action. The lecturer was able to show the way, and to cheer and encourage by example, sympathy, and advice; but the internal impulse to study was to be given by the student himself. It was always, however, to be borne in mind, that the course of study and the examinations to be gone through were ordained by the authority which has power over the different licensing and qualifying bodies. Whatever the feeling that might be engendered, it would be for the student's welfare and after-success strictly to adhere to the plan recommended; for it was constructed, or rather it might be used, in conformity with that which was the character of all good education—namely, to give useful knowledge, and at the same time to cultivate the mental power, by which a well educated man could always continue to educate himself. The effect of medical studies upon the intellect was then considered; the training of the powers of attention and of memory being of primary importance, and afterwards the faculty of judgment, observation, and close reasoning; the labour of such cultivation, and the means whereby the difficulties could be overcome, being set forth by a reference to human anatomy, physiology, and chemistry; the lesson of an orderly arrangement was also drawn from the study of physiology and chemistry, and *materia medica* was instanced as a kind of trial or test of the mind, as far as such was concerned. After such a preparation, the student was able to advance to the study of medicine, surgery, and midwifery, which would be to him all-important, as from them he was to learn the art to which his life was to be devoted—the art which related to the preservation and restoration of health, and the alleviation of human suffering, the true art of which was not a mere guesswork of empiricism, but an art based on observation and supported by science—a study as elevating as it was instructive, and one in which the student would find ample occupation, as it would test most severely his power of memory and observation and the calmness of his judgment. The necessity, then, for cultivating the power of observation was enforced. For in studying medicine, and still more in practising medicine, as every disease was a problem half veiled in darkness and only half known, and as every patient presented not only what was known, but something that was peculiar, the practitioner had to make a constant reference to his memory and to his judgment; it being to the discriminating exercise of observation that we were indebted for all that was known of the causation of disease, of the recognition and interpretation of symptoms, and of the safe and efficient mode of administering remedies. The importance of constantly aiding the teaching in the lecture-room by the practice of the hospital was then insisted on. Both methods of study were absolutely necessary, and were to be pursued together. The knowledge contained in books was to be imprinted by the lesson of the ward; and the actual phenomena of disease were to give life and interest to the systematic description. By the bedside the student would be taught to exercise his senses, how to recognise the origin and the progress of disease, how to elicit a clear and concise history, and how to sift and balance the evidence concerning it. He would also learn how to connect symptoms with pathological changes, and how to modify remedies and appliances to suit special requirements. No student would do justice to himself or his art if he should neglect either mode of teaching. The half-uttered denunciations of the present day against lectures were due to their former abuse and to the neglect of clinical instruction. If both methods of study were made to aid and complement one another, the end in view would be best accomplished. The student was recommended to repress all independent inquiry, to accept what was told him without seeking to pass beyond it, and to be satisfied with what might be termed the routine of science, until he was quite sure that he would avoid confounding probability with ascertained fact. For as, in his case, speculation could not be corrected by direct experiment, and as his imagination would not be kept within bounds by a sufficient

breadth of knowledge, he would, in all probability, arrive at conclusions which were utterly untenable, and form inferences which a deeper study would have shown him to be impossible. After alluding to the obligations of the profession, its trials and difficulties, the lecturer reminded the student that the college-life possessed peculiar advantages as a training for the moral faculties, as well as the mental; and expressed the hope that he would emerge from its influences loving truth and honour, and actuated by high and noble motives in his dealings with others. In this spirit, if he were true to himself, he would never have reason to regret that he had entered upon a profession which had not only the power of cultivating the mind, but of purifying the heart.

"Yea, when the shattered globe shall rock in the throes of dissolution,  
Still will he stand in his integrity, sublime, an honest man."

#### LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.

THE Introductory Lecture was delivered by Dr. W. CARTER, Lecturer on Botany to the School, and Medical Officer to the North Dispensary. Addressing himself partly to new and partly to older students, the lecturer said: "Using the word medicine in its broadest sense, viz., as synonymous with the art of healing, I will presume that you have made up your minds that you are fitted for it, and it for you; that, after reflecting on your capabilities of body, mind, and temper, you have attained a well-grounded conviction that this profession will be better adapted for you than any other." Considering, then, the apparently formidable array of subjects, on the study of which they were about to enter, he commended to them the consolation given by the dial-plate to the discontented pendulum, when he suddenly stopped swinging through fright at the work which had to be got through. He did not complain of six strokes, after finding that he could manage that number with comfort, but of millions. "Very good," said the dial-plate, "but recollect that, although you may think of a million strokes in an instant, you are required to execute but one; and that, however often you may hereafter have to swing, a moment will always be given you to swing in."

The difference between preliminary education and that on which the students were about to enter having been pointed out—viz., that every subject of study in the medical curriculum had a practical side—the lecturer pointed out some very obvious truths, such as that when the hour for a lecture was announced, it was not five minutes after the hour that was meant; insisting on the importance of attending to this as a means of forming a habit of the greatest value to the medical man, on whose punctual fulfilment of an engagement much often depends; that they came to a school of medicine to learn how to mitigate or cure disease, and should never, therefore, stop short anywhere on the way, charmed with merely accessory subjects, or captivated by simply the intellectualities of medicine, as distinct from its practice; that the truest guide to a successful practice was a large experience, and that the man who refused to listen to the teachings of a rational empiricism—who refused, for example, to give a dose of medicine till perfectly sure as to the theory of its action—was like a man who declined to accept the revelations of the microscope so long as he had any doubt about the undulatory theory of light; and that in order to gain this experience the hospital-wards should be visited every day, and the progress of cases carefully noted. In illustration of the value of the last practice, the example of Laennec was quoted, the minute history of nearly four hundred cases which he drew up when a pupil at La Charité serving as the groundwork of all his future researches and discoveries. On the subject of reading, every man was advised to be his own measure as to the quantity to be gone over, no more being at any time read than could be healthfully assimilated; and reading and practice being made mutually illustrative—the folly of reading about disease merely, and imagining that it could be thus understood, being especially insisted on. The practice of reading too little, and relying on some manual which presented the whole circle of the medical sciences in duodecimo, was deprecated as strongly as the habit of overloading the brain with too much reading; and the student was advised to study with a view to possessing well, in which case he would not fail to pass, and not to look at everything in the light of an examination.

To the students who were drawing near the close of their academical career the lecturer addressed some special remarks, chiefly with reference to their conduct in practice. He directed attention to the advisability of a study of hygiene, even though it were not yet a compulsory subject for many diplomas; to the advisability of caution in the giving of certificates; to the folly of the not unprevailing fashion of adopting a specialty for the mere purpose of getting on, without special education for its exercise; to the temptation to write of peculiar cases and peculiar methods of cure; and to the still more dangerous practice of enunciating novel dogmas in medicine on insufficient grounds and from doubtful motives; and lastly, to the temptation which many young men had to

relax all mental effort, and to settle down into a lazy routine so soon as they had gained their diplomas—warning them that if, with human life to deal with, and the honour of a ceaselessly advancing profession to maintain, they ever permitted themselves to do so, they would be morally guilty, and only less so than those who, from interested motives, disseminated principles directly injurious to life and health.

#### LEEDS SCHOOL OF MEDICINE.

DR. CLIFFORD ALLBUTT, President of the School, delivered the Introductory Address. He said he hoped that his hearers would bring back with them the same free, joyous, and hopeful spirit to their work which they had enjoyed in their recreation. He himself rejoiced in a holiday as much as any, but he thought there was one greater enjoyment, and that was the returning home with clear brain and steady pulse, full of courage for duties. No questions could be more urgent than the two which he would now endeavour to answer, viz.: first, What is disease? and, second, Can we cure it? He then referred to the various ways in which these two questions had been answered, in various ages of the world; and he pointed out how important the knowledge of the opinions of the past was to those who would really understand the present. During the present century, the rapid development of anatomical knowledge, and a growing sense of the awful complexity and mystery of the human frame, had deterred men from having a lively faith in their own power of usefully interfering with it. Hence a school who disbelieve in medicine and would leave all to nature. For his own part, he held this doctrine to be as dangerous as the more ancient doctrines, which allowed men to undertake cures in rashness and ignorance. He believed the powers of medicine—when guided by acute intelligence and tact, an extensive knowledge of remedies, and a wide acquaintance with science—to be astonishing to one who cannot but feel, on the other hand, the difficulties and the dangers of the work to be done. But he believed it to be of enormous importance to take care that the hand was guided by an active and observing mind, with the full light of modern observation and experiment, and, above all, by true conceptions of the nature of disease. Hence the urgent need of a true answer to the question—What is disease? In times gone by, nay, even now, there was one very common answer; namely, that disease was something foreign to a man, something which had to be purged out of him, drawn out of him by blisters, expelled through the pores of his skin, or otherwise eliminated. But this theory must be given up, and its place taken by the view that the human body is like the solar system—a system of parts moving together in balance and harmony. In health, this movement should be so even that all our bodily functions go on unconsciously to ourselves; and disease, on the contrary, is that state when these movements are disordered either by some disturbance from without or by some failure within. The medical art consists, then, not in the hope of expelling disease and leaving a sound man behind, but in learning the balance and harmony of the functions, detecting their first deviation from true running, and finding means for helping the system to recover its equilibrium. Dr. Allbutt described the important information of disordered nutritive balance which the thermometer had revealed in fevers, making their treatment in many cases impossible without watching the thermometer. He explained, also, how in this way it had been discovered that death in many cases of fever was directly due to the overheating of the system, and that this mode of death resembled that called sun or heat stroke, and could be induced artificially in animals. Hence the rational and wonderfully successful method of treating fevers by judicious applications of cold, or coolness, in exact proportions to the indications of the thermometer; a practice long ago recommended by Currie, largely extended within the last few years in Germany, and which had lately received brilliant illustration in some cases published by Dr. Wilson Fox. The next point which the speaker took up was that of the individual treated. The same disease in different persons presented often quite distinct features, and it was for the physician to recognise this, and not to rely upon stock formulas, but to treat the individual as a whole. Probably, much might be done by dividing people into classes, according to the chief varieties of constitution and temperament. By recording and putting together all the various complaints which ran in particular families, an unsuspected relationship might often be detected between two diseases which at first sight, and seen separately, appeared wholly different. The various morbid tendencies of rheumatic, gouty, scrofulous families, etc., were then sketched, and a new class of persons was described, whom the speaker proposed to call the neurotic class, and who presented certain marked features, both in health and disease. The lecturer desired the younger students to remember that at Leeds there was no intention of instructing them in systems of opinion, in dry dogmas, or in strings

of hard words; but they would be taken to Nature and to the bedside, and there so associated with their teachers that, on the one hand, the teacher would freely express to them his ideas, his difficulties, his doubts, and his ignorance, and would lead them to see the movement and springs of his own mind and knowledge; the student, on the other hand, would, by inquiries and criticisms, keep alive in the teacher a dread of standing still, a freshness of mind, and a continual openness to new ideas and discoveries. The teacher would give to the pupil accumulated knowledge and maturity of judgment; the student would infuse into the teacher flexibility of mind and renewed enthusiasm. In conclusion, the speaker earnestly called upon his hearers, old and young, to give the heart to their work. "In your own lives," the speaker said, "strive not for things afar; cast not, as we are wont to do, all blessings save gold in the face of God; but learn to see and to delight in those simple pleasures which ambitious men too often trample upon. He is happiest who can gather flowers in every pasture, and man can find no better earthly reward when his work is done than cheerfulness and contentment."

#### SHEFFIELD SCHOOL OF MEDICINE.

THE Introductory Lecture was delivered by Mr. ALFRED H. ALLEN, Lecturer on Chemistry. He said that the advantage of a study of chemistry to the student and medical practitioner is daily becoming more widely recognised. It is not sufficient to say to chemists, "Prosecute your researches and give us the benefit of your discoveries," but there should be an earnest desire to keep pace with the progress of scientific discovery in all that relates to the practice of medicine. Believing that no effect is without its cause, we should leave no means untried to ascertain *why* various remedies produce certain physiological effects; and great as has been the advance in this direction of late years, much more remains to be done. The interesting researches of Matthiessen and Wright on the derivations of morphia and codeia, and the curious change of physiological action established, are a striking illustration of the assistance rendered by chemistry to medicine. Speaking of the nature of infection, the lecturer said that, although the question of spontaneous generation can scarcely be said to have met with a final solution, the general balance of evidence seems at present to be against it. The majority of biologists are strong advocates of the germ-theory of infectious disease—a theory which has many arguments in its favour, and has met with great additional support from the recent beautiful researches of Dr. Thudichum. But there is another very ingenious theory due to Mr. Simon, which also explains the extraordinarily rapid development of infectious disease while ignoring the multiplication of germs by fission. Mr. Simon supposes that the infectious principle of small-pox or other disease has the power of causing some chemical change in the body analogous to fermentation, with formation of a larger or smaller amount of the specific poison, and that the patient has the disease severely or lightly accordingly. By vaccination, therefore, all the substance susceptible of change by the virus becomes so altered, and an additional inoculation can produce no further quantity, so the person becomes insensible to its influence. A very minute portion of virus has the property of causing the chemical change in an almost infinite quantity of convertible matter—the matter so changed having all the characters of the original virus. Some years ago Mr. Simon obtained the opinions on the question of vaccination of upwards of five hundred professors of medicine and surgery at various universities and hospitals, and the striking accordance in the views of these competent authorities is a most convincing proof of its extreme value. Of all those consulted, none doubted the efficacy of vaccination as a preventive agent, and but very few believed that any disadvantage could possibly attend its universal employment. Yet the enforcement was at one time a dead letter with respect to Sheffield; and the House of Commons recently inserted a clause in the Vaccination Act, making two small fines the maximum penalty for omission of the precaution, thus virtually permitting a man to buy the right to spread death, disease, and disfigurement. This was only prevented from becoming law by an amendment of the Upper House. Perhaps it might be found practicable to adopt a somewhat similar course to that of Mr. Simon, to obtain the opinion of every qualified practitioner in the country on that confessedly difficult subject for legislation—the terrible scourges of errant humanity known as "the contagious diseases." If, in the probable absence of any active proceeding on the part of the Government, one of the recognised medical journals would take the necessary steps to obtain such a registration of opinion as that suggested, the expression could scarcely fail to have its due weight with Parliament, as it would be the result of the collective experience of those who, from their position and education, are the most qualified judges of the moral, social, and physical effects of those diseases.

On the subject of cholera the lecturer said: After all that has been written and said on the subject, the real cause and origin of cholera have scarcely been ascertained beyond doubt. The absolute immunity which some places (*e.g.*, Birmingham, Lyons, Versailles, and Würzburg) have enjoyed from its attacks, while it has raged fiercely in localities immediately adjacent; the well-known deterrent effects of the sea upon its development, and various other circumstances, all seem to point to some suitable condition of the soil as necessary for its virulent development—places where the underground water is subject to great changes of level being apparently most liable to its attacks. But, whatever other conditions may be necessary or accessory to its development, there can be no doubt that impure water is one of the principal sources of infection; and some observers have gone so far as to assert that the fact of a person having contracted cholera is an absolute proof of his having imbibed choleraic germs together with the excremental matter of a previous sufferer. It is quite certain that not only cholera, but all zymotic diseases, are the result of bad sanitary arrangements, unworthy of any community professing civilisation; and the epidemics from which we so frequently suffer should not be regarded as visitations from heaven, but as the direct and logical consequences of our own neglect of sanitary matters. The lecturer hoped we may live to see the time when the elements of sanitary science will be taught with "the three R's" to every child in the kingdom. The University of Dublin has gained a most honourable distinction by being the first to establish a much-wanted degree in sanitary science; and he trusted this step in the right direction will meet with all the success it merits, and lead to similar advances in other universities.

#### THE LONDON SCHOOL OF DENTAL SURGERY.

ALTHOUGH it is not the custom to inaugurate the session by a general address to the students, as at the medical schools, Mr. TURNER, the newly appointed Lecturer on Mechanical Dentistry, at his opening lecture, offered some introductory remarks to the students entering for the first time on the study of dentistry, an abstract of which we now present to our readers. In the course of his address, the lecturer referred to the responsibility which attached to those entering a profession which has only of late years assumed an organised condition in this country, which has yet to pass through many phases of modification and reform before it can finally be established in the position in which its members aspire to place it. After asserting the title of dentistry to a position amongst the professions, Mr. Turner proceeded to point out that this profession was not so circumscribed in its field of work as might be supposed, and not only advocated an extended education as demanded by the College of Surgeons for the licence in dental surgery, but urged the students to aim higher, and, if possible, to pass through the complete curriculum required for the membership of the College, which qualification they should strive to obtain. He alluded to the number of pupils of the school who, following out this higher object, had raised the dental profession by good work in other departments of the healing art besides their own. Strictures had, indeed, been passed by some persons on the extensive curriculum demanded of dental students; but, on the other hand, the leading men in the profession had acknowledged the advantages they had received from the liberal education insisted on. He alluded to the improved social position of dentists since he had commenced his career, and the scientific spirit now characteristic of many in their ranks; and in this he paid a handsome tribute to their brethren in America. The lecturer then proceeded to give an interesting and comprehensive retrospect of mechanical dentistry, in which he alluded to the valuable labours of Mr. Hepburn, his predecessor.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At a meeting of this corporation held on the 2nd instant, the following office-bearers were elected for the ensuing year:—*President*—J. G. Fleming, M.D. *Visitor*—George Buchanan, M.D. *Treasurer*—John Coats, M.D. *Honorary Librarian*—J. D. MacLaren, M.D. *Vaccinator*—James Dunlop, M.D. *Councillors*—The President and the Visitor, *ex officio*; W. Weir, M.D.; James Stewart, M.D.; R. S. Orr, M.D.; R. H. Howatt, M.D.; James Steven, M.D. *Board of Examiners*—Andrew Fergus, M.D.; G. Buchanan, M.D.; R. S. Orr, M.D.; W. Leishman, M.D.; W. Lyon, M.D.; Eben Watson, M.D.; James Morton, M.D.; R. Perry, M.D.; P. A. Simpson, M.D.; A. Lindsay, M.D. *Clinical Examiners in Medicine and in Surgery*—The Physicians and the Surgeons of the Royal Infirmary. *Examiners in Arts*—John Coats, M.D.; J. Steven, M.D. *Inspectors of Drugs*—W. Eadie, M.D.; J. Morton, M.D. *Representative to the General Council of Medical Education*—J. G. Fleming, M.D.

## BRITISH MEDICAL JOURNAL.

SATURDAY, OCTOBER 7TH, 1871.

## THE MISSING INTRODUCTORY.

WE hope our readers will think that they have no reason to grumble at the selection we have made for their benefit from the introductory addresses of the new session. There was this year a more than ordinary wealth of oratory from which to select, and we could name more than one lecture besides those of Mr. Le Gros Clark and Dr. Charlton Bastian with which we should have been glad to adorn our pages. We have again to congratulate St. Bartholomew's on the wise and truly British determination to do their talking chiefly after dinner, and to convert the annual gathering into an occasion of gastric rather than of cerebral congestion, and of ventricular rather than mental fullness. There is good authority for regarding that which goeth into the mouth as less open to objection than that which cometh out. Besides this introductory, there was also another, we hear, which, as the critical moment drew near, was missing. Twenty-four hours before one of the introductory lecturers was about to face a critical audience, the bag which had contained his MS. was floating empty down the Tay, stripped of all its belongings by ruthless and sacrilegious hands. However, the lecturer proved more than equal to the occasion; and it is the general belief that the real impromptu cannot have been surpassed in excellence, if indeed it were equalled by, that which had been carefully prepared.

The lectures which we present *in extenso* speak for themselves. Mr. Clark's is pregnant with the interest which attaches to the revival of the glories of a great historic school and hospital, and happily combines tribute to the great ones of the past who connect the history of St. Thomas's with the history of medicine, of surgery, and of science, with a clear sense of the modern *status*, and an appreciation of the larger responsibilities which attend a school that aims at filling a great place in modern education. Dr. Bastian's lecture deals with a more abstract question. We shall not need to do more to-day than to bespeak for it the steady attention and careful thought of our readers.

We have now for some years taken pains to put in the foreground what seems to us the most important problem in medical science—the solution of the questions of the origin and correlations of disease. At the root of the inquiry lay the question of the modes of origin of primitive form of life, and the truth of the “germ-theory”. In this important inquiry, and in familiarising the professional mind with the different aspects of the question to be solved, we have had from the first the invaluable assistance of Dr. Bastian; and his active mind and remarkable powers of investigation have since carried him into the foremost rank amongst physical investigators of the purely scientific parts of the subject. He returns to-day to the application of these researches to recognised and familiar medical doctrines, and we shall not withhold the opinion that his argument is not only most able and interesting, but is marked by so much originality and well-applied illustration, that it marks an era in medical thought, and is destined to light up a discussion of which the end is not yet clearly to be foreseen.

Looking through the abstracts of the introductions which it is our misfortune to be unable to publish in full, we miss from all some sentences, which surely must have been delivered, and which ought to have been allowed to stand. Surely some one must have had the courage to tell the students the plain truths which they ought to know, and to vary the uniform tone of congratulation, which acquires at last a mawkish flavour. Or is there a missing introductory, of which the abstract has not been sent to us, and which ran briefly thus? ‘The entrance to the medical profession has lately been barred by a not very lofty or

impassable barrier. Gentlemen of seventeen years of age, about to enter on a liberal profession, are required to prove that they possess the elements of a liberal education; that they can read, write, and sum, and have a smattering of French and Latin; Greek is “not required”, not even the alphabet; and chemistry is optional, even the elements. About one-third of those who desire the privilege of dealing with the lives of their fellow-creatures have failed to pass the limits of duncedom, and something like thirty per cent. are unable to pass the preliminary examination. Of those who pass through and become students of our schools, and of the schools themselves, there is something to be said, which, on this opening day of our session, demands the most earnest consideration.

‘There stands in Lincoln's Inn Fields a venerable edifice which is not credited with extreme severity of tests, or with more than usual unwillingness to swell the number of its members. Recently, however, in obedience to a demand which arose throughout the profession, and indeed throughout the country, the College of Surgeons raised the standard of its examinations to a position which rendered it no longer probable that those whom it had authorised to practise in civil life should in large proportions be ignominiously rejected as ignorant of the elements of professional knowledge, and unfit to be trusted with the lives of soldiers and sailors. In the outcry which led to this gentle and slow elevation of the test, the teachers of the schools were foremost, and some of the students applauded. It certainly cannot be said that it is now too high. Our schools—we dare not say our school, for this school has (in every case) been extremely fortunate in passing its pupils; but our schools have failed to rise even to this low level. Of 603 candidates who presented themselves for primary examination in Anatomy and Physiology in the period dating from July 19th, 1870, to May 10th, 1871, 179 were rejected—about 30 per cent. Of 382 candidates who presented themselves for the final diploma, 76 were rejected. More than this, it may be stated as a necessary and inevitable fact, that so large a proportion of total failures indicates a general failure to come up to the height of the standard; and where so many are perforce rejected, a great many have to be passed through “with a shrug”. It will be generally acknowledged, and each of us ought individually to remember, that this discloses an altogether unsatisfactory state of things. It behoves us to know with whom the fault lies, in order that all may not suffer for the fault of the few. We shall never thoroughly improve till we face the truth. To know what is wrong, we must know whence the failures come, and whence the successes; and, to do this, it is essential that the College of Surgeons should publish every year returns of the number of candidates coming from each school, the numbers passed, and the numbers rejected. Good schools and good scholars will be encouraged; bad schools will be stimulated to improve, or will have to make way for better. Judgment will be founded upon results. At present, we are all congratulating ourselves, and some of us at least are living in a fools' paradise, which we are inviting fond parents to send their sons to share with us. One thing is wanting—more light. Let us have light; these returns, and nothing else, will give it.’

This is an abstract of an introductory lecture which must, we are persuaded, have been delivered somewhere, but of which the manuscript failed to reach us.

## DENTAL DIPLOMAS.

WHEN the long agitation for satisfactory means of organising dental education on a satisfactory footing, and establishing an adequate test for practice, resulted in a supplementary charter being granted to the College of Surgeons of England, and in that body taking in hand the business of organising the dental profession twelve years ago, there was reason to hope that the future of the profession was satisfactorily moulded. It was expected that so great a majority of the respectable existing practitioners of dental surgery would join the College, as to

make the licence in dental surgery henceforth the indispensable necessity of every respectable practitioner entering the profession of dentistry. The following figures, however, which we have obtained, show how far that hope has been disappointed. The number of dentists in England is, we are informed by Mr. Fox, 2000; in Ireland, 150; in Scotland, 25. The numbers of those who presented themselves for examination before the expiration of the time of grace are: in 1860, 99; 1861, 25; 1862, 23; 1863, 116; in all, 263—an average of 65 *per annum*. Those who have taken the diploma after fulfilling the curriculum were: 1864, 4 in number; 1865, 2; 1866, 10; 1867, 4; 1868, 3; 1869, 6; 1870, 8; 1871, 6; in all, 43—in eight years, an average of 5 *per annum*. This, it will be acknowledged, indicates a dead failure. It is not surprising, therefore, that a movement has been set on foot in reference to dental reform aiming to remedy this disaster; and the medical profession and the general public should alike take interest in the nature and progress of the proposals.

A Dental Diploma Committee has been formed, in order to persuade the Royal College of Surgeons to open its doors again to those dentists who were in practice prior to September 1864, but who did not present themselves for examination within the time of grace allowed by order of Council of the College. This holding back from attachment by examination and diploma with the College of Surgeons was in a large manner produced by a division of feeling, that existed at the time in the dental profession, as to what were the best means to adopt in order to raise the position of its members in the esteem of the medical profession and the public. The division of opinion was at the time mischievous, and has since been a stumbling-block in the progress of much reform in this special branch of surgery. It is contrary to all precedent that an order of Council of a College should limit the time wherein men may present themselves for examination, if they can show that they were engaged in the legitimate practice of the profession at the time when the Act of Parliament was passed empowering the College to hold such examinations. In a word, no legislation is intended to be retrospective (nor was this so intended by its Parliamentary promoters); but, by the resolution passed by the College of Surgeons, it has become so; and to the existence of this state of things we must mainly attribute the difficulty of making such changes in the profession as require uniform and concerted action.

By a resolution of Council this regulation can be revoked; and we have reliable information on which to found our assertion that such a step would bring in a large number of men of undoubted skill and position to take the diploma in dental surgery. Let the dental profession be once united by a common bond such as would exist if each member of it possessed the L.D.S., and we shall have a great motive power by which we can effect urgent and valuable reforms.

The want of this is felt, and we can hardly think that, if the matter be put in its true aspects before the College of Surgeons, they will allow much time to elapse before they grant the petitions of the Dental Diploma Committee, representing, as it does, the wishes of a large and daily increasing number of the dental profession. There can be no valid reason why practitioners actually in practice at the time of the granting of the charter should not be allowed to submit themselves to examination at any date convenient to themselves; and we advise the withdrawal of the obnoxious and unnecessary restriction of date, which has proved injurious to the objects of the College and the interests of the dental profession. We cannot see that it has any foundation in reason more than in expediency, and it is certainly contrary to precedents.

MR. JOHN FOSTER has been elected President of the Bradford Medico-Chirurgical Society for 1871-72, in succession to Mr. E. Sugden.

THE funeral of Mr. Samuel Solly, F.R.S., took place on Saturday at Chislehurst Church, Kent, in the presence of a numerous assemblage of the medical profession. It is contemplated by his former pupils at St. Thomas's Hospital to erect a memorial to his memory.

DR. HENRY S. WILSON has been appointed Demonstrator of Anatomy in the University of Cambridge. Dr. Wilson was formerly demonstrator under Professor Goodsir in Edinburgh.

DR. JOHN LOWE of Lynn has been appointed Medical Attendant to the Household of their Royal Highnesses the Prince and Princess of Wales at Sandringham.

THE deaths in Paris last week amounted to 831. Of these, 40 were from bronchitis, 35 from pneumonia, 61 from diarrhoea, and 35 from typhoid fever.

THE Queen has contributed £100 to the Working Men's Extension Fund for the Queen's Hospital, Birmingham. Baroness Burdett-Coutts has consented to lay the foundation-stone of the new buildings, which will have space for 190 beds, and suitable out-patient and separation wards.

THE Secretary of State for War has, with the concurrence of the Lords Commissioners of the Admiralty, appointed Sir Alexander Armstrong, K.C.B., Director-General of the Medical Department of the Navy, a member of the Senate of the Army Medical School at the Royal Victoria Hospital at Netley.

HER MAJESTY has been suffering quite recently from a sharp rheumatic attack in the foot and hand, and the brief notices of indisposition in the *Court Journal* have caused some anxious misgivings; but we are happy to state upon the best authority that the Queen is doing very well, and that there is no cause for anxiety.

THE fatal cases of small-pox registered in London last week, though less than in the two previous weeks, when they were 57 and 89 respectively, were 39 in excess of the corrected average number in the corresponding week of the ten years 1861-70. The deaths from diarrhoea, which in the five previous weeks had steadily declined from 487 to 205, further decreased to 153 last week, which was, however, just double the corrected average number in the corresponding week of the ten years 1861-70.

#### THE LONDON MEDICAL SOCIETIES.

THE meetings of the session of the Royal Medical and Chirurgical Society commence this year in October; but, in consequence of the incomplete state of the alterations which are being made in the Society's premises, the first meeting will not be held until Tuesday, October 24th.—The first meeting of the Clinical Society will be held on Friday next, at half-past eight P.M.

#### MEDICO-LEGAL EXAMINATIONS OF THE PERSON.

AT the annual meeting of the Herefordshire Medical Association, held at Hereford on September 27th, the following resolution was passed unanimously: "That this Society hereby expresses its sympathy with Messrs. Barnett and Chattaway in the painful position in which they have been placed by the unjust comments which have appeared in several publications upon their conduct in the recent case of suicide at Kingsland. This Society is of opinion that their conduct, acting as they did under the written order of the coroner, was marked throughout by delicacy, kindness, and propriety." We may say that, looking to all the facts which have transpired, we are of opinion that this resolution is entirely justified. The unfortunate lady being truly in custody of the police, and the coroner having issued an order requiring these gentlemen to attend for the purpose of making a physical examination, it is certain that they, both by their manner and by the delays which they made, evinced every desire to show consideration for the feelings of the unhappy woman. It is, of course, quite proper for medical men to attend under such an order—as, for instance, in the case of Boulton and Park, and numerous others. It seems, however, equally clear, and always has been so, that a physical examination cannot be enforced against the wishes of the accused person; and this cannot be too clearly borne in mind by medical men under similar circumstances.

## ARMY MEDICAL SCHOOL.

THE winter session of the Army Medical School commenced on Monday, October 2nd. Dr. Parkes, F.R.S., delivered an admirable introductory address on the occasion in the presence of the heads of the service. A large number of candidates for commissions, as well as commissioned medical officers of both services, were present.

## COTTAGE HOSPITAL AT TENBY.

ON September 22nd, one of these useful institutions was opened here by the Mayor, who, in his robes and attended by the members of the corporation, walked in procession from the Town Hall to the building, where he was received by the medical officer, Mr. J. Griffith Lock, and the Honorary Secretary and Treasurer, Mr. H. Forde, and several of the trustees. After a careful inspection of the building by the Mayor, the rector, the Rev. G. Huntingdon, offered a prayer; after which the Mayor and Dr. Dyster addressed the visitors present, and the building was declared duly opened. The idea of a hospital was suggested by Mr. Lock last November; and at a public meeting held then, the proposal was so well received that the committee then chosen immediately went to work, and the effect is that in a capital situation there is a comfortable building containing a kitchen, bath-room, lavatory, nurses' bedroom, two wards with two beds in each, a special ward for one bed, a committee or operating-room, a store-room, and an extra bedroom. There is also outside the building a mortuary, which can at all times be used as a laundry—not a very judicious arrangement if any cases of infectious disease should be admitted. Among the contributors to the Building Fund are: Dr. Dyster, £230; Mr. C. Allen, £35; Mr. Scourfield, M.P., £20; Mr. J. Griffith Lock, £21; Mr. Chater, F.R.C.S., £10:10; Mr. Saunders, £20:10.

## NEW PORTUGUESE MEDICAL JOURNAL.

WE have received the first numbers of a new medical journal, which has lately made its appearance in Lisbon with the title of *O Correio Medico*, under the able editorship of Dr. Alves Branco, Physician to the Royal Hospital of San José, and of Dr. Silva Amado, Pathologist and Curator of the Museum at the Royal School of Medicine of Lisbon. Its first numbers are vouchers of promise for its future success; and from the information which is afforded in them, more especially upon the "African Lethargus," a disease but little known to British medical men, we feel bound to recommend this journal to the profession as a valuable contribution to medical literature.

## MANCHESTER MEDICAL SCHOOL.

THE winter session opened on Monday, October 2nd, with an address by Mr. Hunt, amidst the most riotous uproar, we should imagine, that ever greeted a lecturer. An introductory address which consists of a series of carplings at and warnings against such advances of modern science as the microscope and the ophthalmoscope, and which vaunts the educational system of the past as contrasted with the present, is little adapted to the tastes or requirements of the day. It is easier, too, to sneer at the theories of Darwin and Huxley, than to confute their arguments. But at the same time it is no less true, that no eccentricity on the part of a lecturer justifies students in behaving more like noisy incoherent Communists than gentlemen entering upon the serious study of a profession which needs as much as any the "white light of reason."

## THE SANITARY STATE OF SALFORD.

OUR Manchester correspondent writes:—The Salford death-rate has for the last five weeks averaged fifty-one per thousand, and has called forth a report from the Officer of Health for the Borough, Dr. Syson. This mortality is chiefly due to the prevalence and fatality of infantile diarrhoea; and Dr. Syson accredits two agents as mainly responsible for this high death-rate—firstly, improper feeding; and secondly, the miasmata arising from open middens, of which he states that there are no fewer than fifteen thousand within the borough. The Officer of Health for Manchester, Dr. Leigh, on the other hand, considers that the consumption of unripe fruit is in a large measure the cause of the

prevalent diarrhoea; but this can scarcely hold good, for, as Dr. Syson observes, the deaths occur at an age when no fruit of any kind is eaten. In this same report he strongly condemns the conduct of the Registrar-General for not only usurping the functions of the College of Physicians, but for acting in direct antagonism to their opinions by prescribing an astringent beverage to meet the evil. The report is an able one, and clearly enough shows that the high death-rate of Salford is not in any way attributable to want of activity or ability on the part of its officer of health.

## NEW ENGLISH HOSPITAL IN PARIS.

SIR RICHARD WALLACE has established on a permanent basis the English hospital in Paris, which during the sieges was maintained at his cost in the Rue d'Aguesseau. Two months ago, the English patients remaining in that hospital, and about twenty of the wounded remaining in the ambulance adjoining, were transferred to a temporary hospital in a suburb of Paris. A new hospital has been established by Sir Richard Wallace, and will be opened on the 15th instant, when the English patients in the temporary hospital, and the two remaining siege-casualties—gun-shot fractures of the thigh—will be transferred to it. The hospital, which is situated in the Route de la Rivoltte, beyond the Porte Maillot, will be called the "Hertford Hospital", in honour of the late Marquis of Hertford, whose large fortune was inherited by Sir R. Wallace. It will contain thirty beds, and the medical staff will consist of Dr. Rose Cormack and Dr. Herbert. From the beginning of the rule of the Commune, Dr. Cormack has done most of the work in Sir Richard Wallace's ambulance and English hospital.

## THE MANCHESTER INFIRMARY AND ST. MARY'S HOSPITAL.

WE learn from our Manchester correspondent that there is a scheme on foot at present amongst the Boards of the Infirmary and St. Mary's Hospital for Women and Children to amalgamate the two charities under one common government—a scheme which in a great measure means adding women's and children's wards to the Infirmary. There are several obstacles in the way, which must be removed before this scheme can be carried into effect; and, amongst others, not the least difficult will be the composition and functions of the respective medical and surgical staffs. The fact, however, that Dr. Reed is in favour of this arrangement, is in itself a strong argument that it will be accomplished. Dr. Reed's desire is to convert the Manchester Infirmary into a sort of medical university, where a student may prosecute the study of every branch of his profession without leaving its walls. In a word, he desires to see the Manchester Infirmary an institution where facilities will be afforded for the study of diseases of the eye, the ear, and the skin, besides the special affections of women and children.

## OPERATIONS AT THE HOSPITALS.

THE first fortnight of the Winter Session is to the metropolitan hospital surgeon a regular campaigning season. He has been for weeks, or months perhaps, accumulating material wherewith to satiate and astonish the youthful Æsculapians. The custom, although sometimes it has a tendency to degenerate into an advertisement, is a good one. By concentrating a number of operations into one day, a great deal of the students' time is saved which would be wasted if the operations were prolonged over several weeks; and, at the same time, the custom affords an opportunity to old pupils who may come to London for a few days to see as much as possible of operative surgery and its improvements. At the London Hospital this week, Mr. Hutchinson removed a large blood-tumour of the scrotum, Mr. Maunder a tumour involving the nostril, orbit, temporal and zygomatic regions of the left side, and Mr. Couper operated for an ununited fracture of the left femur, sawing off the edges and bringing them together by drilled holes and cat-gut ligatures. At University College Hospital, Mr. Erichsen performed an amputation of the thigh, Mr. Berkeley Hill varicocele by Wood's new spring, and Mr. Streatfield extirpation of the eyeball. A few small operations were also performed in the theatre.

## THE MIDDLESEX HOSPITAL.

THE vacancy caused by the promotion as extra-surgeon of Mr. George Lawson has been filled up by the appointment of Mr. A. Clark, a former house-surgeon of the hospital.

## UNIVERSITY COLLEGE HOSPITAL.

A VERY beautiful mosaic tablet, by M. de Triquetri, has been placed in one of the wards of this hospital, in memory of the late Mr. Edward Yates, who bequeathed an endowment of £46,000 to the funds of the hospital. The tablet was erected by Dr. Hare, late Physician to the Hospital, and Mr. Yates' trustee, and rests on a massive polished chimney-piece of Peterhead granite.

## THE NATURAL SCIENCE SCHOLARSHIPS AT ST. MARY'S HOSPITAL.

THE open scholarship in Natural Science, lately established at St. Mary's Hospital Medical School, has this year been gained by Mr. E. J. Edwards. It is of the value of £40 per annum for three years. The Exhibition of £20, awarded at the same examination, has been gained by Mr. Giles.

## THE LONDON SCHOOL OF DENTAL SURGERY.

SINCE the opening of this now flourishing school in 1860, the original staff of lecturers remained unbroken until very recently, when Mr. Ibbetson and Mr. Hepburn resigned their lectureships on the Anatomy and Physiology of the Teeth and on Mechanical Dentistry respectively. These vacancies have been filled up by the appointment of Mr. Charles S. Tomes and Mr. James S. Turner. The number of entries at this school promises, we understand, this year to be fully as large as usual.

## DEATH OF DR. BEAUPERTHUY.

INTELLIGENCE has been received that this physician expired suddenly, only two days after his interview with Dr. Milroy, who, it will be recollected, was sent out to the West Indies by the Colonial Office to investigate the reality of the alleged cure of leprosy by a plan of treatment which Dr. Beaupertuy has for a considerable time followed.

## ROYAL COLLEGE OF SURGEONS.

THE annual registration of medical students at the metropolitan hospitals was commenced on Monday last, and will be brought to a close on the 16th instant. The examinations for the present session will take place on the 4th and 10th of November respectively, and the examinations for the Fellowship on the 18th. The library and museum were reopened on Monday last. In the latter, several additions have been made, especially a rare and valuable whale, obtained through the liberality of Professor Erasmus Wilson.

## THE ASSOCIATION OF CERTIFYING MEDICAL OFFICERS.

THE fourth annual general meeting of the Association of Certifying Medical Officers of Great Britain and Ireland will be held at the Adelphi Hotel, Liverpool, on Friday, October 20th, at 2 P.M. The members will afterwards dine together. Gentlemen intending to be present at the dinner are requested to notify the same to the Honorary Secretary, Mr. Stansfeld, Redlands, Bristol, on or before Tuesday, October 17th.

## MEDICINE AND THEOLOGY.

DR. CHARLES HENRY LEET, assistant-surgeon Royal Engineers, Chatham, has, on the nomination of the Rev. J. G. Bailey, M.A., chaplain to the Garrison Hospital, Fort Pitt, been formally admitted and licensed by the Lord Bishop of Rochester to the office of reader in lay orders of the Church of England. The Chaplain-General of the Army, at his recent visit to the garrison, expressed his approval, and also his earnest wish, that many more officers might be induced to do likewise. He regarded the assistance of such officers, holding a recognised position in the Church of England, as invaluable to the military chaplains, and gave his assurance that, wherever these readers might be stationed, whether at home or abroad, he would take the liveliest interest in their work and welfare.

## DEATH UNDER CHLOROFORM.

AN inquest was held at Manchester this week (says the *Manchester Examiner and Times*) before Mr. E. Herford, the city coroner, respecting the death of a drayman named Isaac Grundy, late of 19, Queen Street, Bedford Leigh, aged 34. On Thursday last deceased was admitted to the Manchester Royal Infirmary, suffering from a fracture of the leg. Mr. J. G. Gordon, junior house-surgeon, attempted to reset the limb, but, after several trials, failed, as the deceased shrank from the operation. Mr. Gordon suggested that chloroform should be administered, and Grundy acquiesced. A rag saturated with chloroform was accordingly placed several times to the deceased's face, and Mr. Gordon repeatedly essayed to reset the injured part, but the deceased could not be got sufficiently under the influence of the anæsthetic, and each attempt was unsuccessful. The pulse of the deceased suddenly ceased to beat, and the usual methods for resuscitation were resorted to, but without effect. Mr. S. Buckley, physician's assistant at the Royal Infirmary, said he had made a *post mortem* examination of the deceased's body, and discovered fatty degeneration of the liver and kidneys. The brain was softened, and the heart flabby and much dilated. The deceased was a powerful man, and appeared as if prone to indulge in alcohol. There was, however, no trace of it in the stomach. The witness was of opinion that death resulted from shock to a dilated heart whilst deceased was under the partial influence of chloroform. He considered that chloroform would not have had such an effect had not the heart been diseased. The jury returned a verdict in accordance with the evidence.

## THE FRENCH AMBULANCE COMMITTEE.

THE Committee of the Ambulances of the French Press during the late siege of Paris, desirous of expressing their sense of the cordial reception given to their delegates in London at the banquets offered at Greenwich by Colonel Loyd Lindsay, M.P., V.C., and in London by the metropolitan medical body, have forwarded for acceptance, through the French Ambassador, gold medals of the Ambulance de la Presse to Colonel Loyd Lindsay, Sir William Fergusson, Sir Henry Thompson, and Mr. Ernest Hart; and have also forwarded bronze medals for the acceptance of the stewards of the London banquet, including Dr. Burrows, President of the Royal College of Physicians; Mr. Busk, President of the Royal College of Surgeons; Dr. Paget, President of the General Medical Council; Sir William Armstrong, K.C.B.; Sir William Jenner; Sir James Paget; and the other hospital physicians and surgeons who associated themselves in this mark of international friendship. Dr. Markheim has, on the part of M. de la Grangerie, the General Secretary of the Committee, accompanied the medals with a gratifying communication.

## HEREFORDSHIRE MEDICAL ASSOCIATION.

THE annual report of this Society has been forwarded to us. It states that the following resolutions have been carried at meetings of the Association. "1. That this meeting disapproves of the system of giving certificates in favour of any particular line of practice, medicine, or article of diet, as derogatory to the profession; and hopes that, in future, the members of this Association will abstain from lending themselves to such a course." "2. That this Association strongly disapproves of medical men publishing scales of charges, or otherwise advertising for practice—the more particularly so when done for private motives under the guise of charity." "3. That it is the opinion of this Association that the utmost caution should be used by all members of the profession in expressing opinions about each other, but especially in giving evidence in courts of law, to the prejudice of any gentleman legally qualified to practise." "4. That the system of gratuitous medical advice and assistance has outgrown all necessary and reasonable limits. With all its acknowledged benefit—and may the full extent of its true charity never be lessened—in the excess to which it is now carried it is largely productive of the serious evil of checking those habits of providence, forethought, and independence, which it is always so desirable

to encourage among the working classes ; and that it will, therefore, be of great advantage to introduce the self-supporting principle, in whole or in part, in the formation of all new dispensaries, and in those already existing, wherever it may be practicable to do so." "5. That the discussion, by members of the profession, of medical subjects with reference to the treatment of disease, in the public newspapers, is much to be regretted : it is futile for any useful result, and seldom fails to compromise the dignity of true science." "6. That in the opinion of this meeting, it would be desirable that medical attendance upon sick assurance societies (clubs) should be exclusive of medicine, and that the rate of remuneration should not be less than 4s. per head *per annum* ; or in country districts, where it may be desirable, for obvious reasons, that medicine should be supplied by the medical attendant, the rate should not be less than 5s. per head *per annum*."

#### CONVALESCENT INSTITUTION IN CONNECTION WITH BETHLEHEM HOSPITAL.

AMONG the local Acts of the recent session was one to enable the Governors of Bethlehem Hospital to establish and maintain at Witley, near Godalming, a convalescent establishment in connexion with, and as part of, Bethlehem Hospital. The statute recites that the charter of the Hospital was granted by his late Majesty Henry VIII for the house and Hospital at Bishopsgate, in the city of London, and an Act was passed in the 22nd of George III, and the mayor and commonalty constituted governors. The original Bethlehem Hospital was destroyed in the great fire of London, and the building substituted was found insufficient. A hospital for the reception and maintenance of lunatics was therefore built in St. George's Fields, and maintained out of the revenues and property belonging to the governors. Further, the statute states that it is of great advantage to the persons so received that the governors should be able to send away from the Hospital, for the benefit of their health, but without relinquishing the care and charge of them as lunatics, such of the same persons as are convalescent and such others of them as the governors may think fit to send away. A convalescent establishment at Witley may be established "for the reception of convalescent and other patients". Regulations are to be made for the new establishment, and the Commissioners of Lunacy are to visit the place as if the same were registered as a hospital.

#### THE SEWAGE OF LARGE TOWNS.

ABOUT six weeks ago, the Town Council of Birmingham had under discussion a scheme in reference to the sewage of the borough, submitted to them by the Public Works Committee. The Council were dissatisfied with the scheme, and appointed a special committee to inquire into the subject and report to a subsequent meeting of the Council. Their report was a very long document ; but their recommendations include the following : The gradual abolition of middens, and substitution of a new privy system, based upon the principle of exclusion from the sewers and weekly collection of all excrementitious matter, solid and liquid. A system to be developed in connexion with the above, of exclusion from the sewers and collection of refuse from slaughter-houses, cattle-markets, urinals, cow-houses, and stables. An experimental trial of the Rochdale and Manchester systems, on a sufficiently large scale, and under the strictest supervision ; and ultimately an extension to the whole town of that system which shall be found to be the most efficient. The imposition of a rate on occupiers, in respect of water-closets connected with the sewers, on a scale to be sanctioned by the Council. The exclusion from the sewers of the refuse from the works of German silver manufacturers, galvanisers, wire-drawers, and manufacturing chemists, and from such other works the refuse from which may, from time to time, be found to interfere with the utilisation of the sewage of the borough, unless such refuse shall, previously to being discharged into the sewers, have been so treated as not to interfere with such utilisation.

## SCOTLAND.

DR. JOHN CHIENE and Dr. Alexander Miller are candidates for the vacant appointment of Assistant-surgeon to the Edinburgh Royal Infirmary.

## IRELAND.

#### THE SANITARY STATE OF DUBLIN.

THE Health Committee of the Corporation of Dublin have, says *Saunders's Letter*, been roused into action by the recent letter of Dr. Grimshaw, which appeared in our columns. Bridgefoot Street has been visited, and an attempt made to get rid of the abominations described. In one of the worst of the houses, we understand, the inspector found two cases of fever, which were removed by a magistrate's order to Cork Street Hospital, making in all seventeen cases from this house within a comparatively brief period. Let it be observed that nothing was done during a period of two months, during which the frightful condition of this and other localities was repeatedly brought under the notice of the committee ; but the moment public attention was called to the subject, the committee began the performance of a long-neglected duty. The committee certainly cannot claim credit for much vigilance or energy when they allowed the state of things in Bridgefoot Street which Dr. Grimshaw described to remain so long unremedied.

#### THE MEDICAL SCHOOL DINNERS, ETC.

##### ST. BARTHOLOMEW'S HOSPITAL.

NEARLY ninety of the old students of this hospital met at dinner in the great hall on Monday evening, Dr. Black presiding. Amongst those present were Sir James Paget, Bart., Professor Owen, Dr. Burrows, Professor Humphry of Cambridge, the Treasurer of the Hospital, and others. After the usual toasts, Professor Owen proposed "Prosperity to St. Bartholomew's Hospital and Medical School", referring in terms of affection to his student days when he was a pupil of John Abernethy, and subsequently to his having given his first course of lectures at St. Bartholomew's Hospital. Professor Humphry proposed "The Health of Sir James Paget", who replied with all his accustomed eloquence and felicity. The toast "The Chairman's Health" was proposed by Dr. Wood, and "The Visitors" by Dr. Monro. Dr. Burrows, the President of the College of Physicians, replied to the toast of "The Medical Corporations." Mr. Luther Holden proposed "The Health of Mr. Willett, the Steward of the Dinner." The meeting proved very successful, and was continued till a late hour.

##### THE MIDDLESEX HOSPITAL SCHOOL DINNER.

THE past and present pupils of the Middlesex Hospital held their annual dinner at the Freemasons' Tavern on Monday evening. Thomas Taylor, Esq., F.R.C.S., occupied the Chair, and there was a large attendance. The toast of the evening, "The Middlesex Hospital Medical College," coupled with the name of Mr. De Morgan, elicited a very warm response. Amongst the other toasts were those of Mr. Taylor, the Chairman ; the orator of the day, Dr. John Murray ; and the Past and Present Pupils, coupled with the name of Mr. R. Lucas, Resident Medical Officer. The success of the evening was in no small measure due to the unusually excellent music of Mr. G. Anderson Critchett, Mr. Semple, Mr. Hailstone, Mr. Turner, and Mr. Burnett ; Mr. Ganz kindly assisting at the piano.

##### THE LONDON HOSPITAL.

THE Biennial Dinner of the past and present students of the Hospital and College took place at the London Tavern on Monday evening : Mr. Curling, Consulting Surgeon to the Hospital, in the chair. There was, we hear, a large attendance of old pupils of the hospital, and the meeting passed off in every respect very successfully.

##### ST. GEORGE'S HOSPITAL DINNER.

THIS dinner, which passed off with more than usual success, was held on Monday evening at Willis's Rooms : Dr. Pitman, Consulting Physician to the Hospital, in the chair. Among those present was Sir John Fisher, who, during the course of the evening, stated that he had

entered St. George's Hospital as a pupil sixty-five years ago. The toast of the evening, "Prosperity to St. George's Hospital and School", was very warmly responded to. The attendance was very large, over one hundred being present.

At St. Mary's, Charing Cross, and the Westminster Hospitals, *conversazioni* were held after the Introductory Addresses.

## THE CHOLERA.

THE Sanitary Council of Hamburg has officially announced that the cholera, which had made its appearance there, is now extinct.

IN Koenigsberg the fatality from cholera is declining. In the week ending last Thursday, 23 deaths were reported, against 52 in the week ending 14th ult. In Stettin, three fatal cases occurred last week.

CHOLERA has broken out severely in Constantinople. A Constantinople telegram states that the Government has ordered a sanitary cordon to be drawn around one of the quarters in Pera ravaged most severely by the cholera. No one is permitted to cross this cordon. The local journals severely criticise this measure as useless, and tending to spread a panic among the inhabitants of the quarter, besides exposing them to privations. A medical man and a priest, purposing to tend the sick, have been prevented crossing the cordon.

A CORRESPONDENCE has taken place between the Local Government Board and the Metropolitan Asylum District Managers on the subject of accommodation for cholera patients in the event of that epidemic reaching the metropolis. The managers, while expressing their willingness to receive a limited number of patients at the Hampstead Hospital, suggest that, as cholera would probably first appear in the port of London, the *Dreadnought* should be used as a floating hospital for the purposes of isolation, and that in each union workhouse a cholera ward should be prepared. In reply to this, the Assistant-Secretary of the Local Government Board, writing on the 29th September, says: "For the purpose of enabling the managers to provide suitable hospital accommodation, in the event of the metropolis being again visited by cholera, the Board proposes to issue an order combining the several unions and parishes constituting the Metropolitan Asylum District into a district for the relief of poor persons who may be attacked by that disease, and directing that the managers of the present Metropolitan Asylum District shall also be managers for the district so contemplated to be formed."

## ASSOCIATION INTELLIGENCE.

### SOUTH MIDLAND BRANCH.

THE next meeting of the above Branch will be held at the Town Hall, Wellingborough, on Tuesday, October 10th, at 2 P.M.

Gentlemen who intend to read papers or cases, are requested to forward the titles of the same forthwith.

J. M. BRYAN, M.D. } *Honorary Secretaries.*  
WM. MOXON.

Northampton, September 11th, 1871.

### BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

THE next meeting of the above Branch will be held at the Council Room of the Midland Institute, on Thursday, October 12th, at 3 P.M.

Mr. Lawson Tait will move that a Committee be appointed to consider the mode of election of the Officers and Council of the Branch.

The following papers are promised:—On some points of Surgical Experience, by Mr. H. D. Carden; Old and New Methods of Water Analysis, by Dr. Alfred Hill; On the Lactic Acid Treatment of Rheumatism, by Dr. B. W. Foster.

Members are invited to exhibit pathological specimens at the commencement of the meeting.

T. H. BARTLEET, *Honorary Secretary.*  
Birmingham, October 1871.

### BATH AND BRISTOL BRANCH.

THE first ordinary meeting of the Session will be held at the York House, Bath, on Thursday evening, October 26th, at seven o'clock. CROSBY LEONARD, Esq., President.

R. S. FOWLER, Bath, } *Honorary Secretaries.*  
E. C. BOARD, Clifton, }  
6, Belmont, Bath, October 1871.

### CUMBERLAND AND WESTMORLAND BRANCH.

THE autumnal meeting of the above Branch will be held at the King's Arms Hotel, Wigton, on Wednesday, October 25th, at half-past twelve o'clock. The President, Dr. ELLIOT of Carlisle, will occupy the Chair.

Gentlemen intending to read papers or cases, are requested to communicate with the Secretary at their earliest convenience.

HENRY BARNES, M.D., *Honorary Secretary.*  
Carlisle, October 3rd, 1871.

### SOUTH WALES AND MONMOUTHSHIRE BRANCH: ORDINARY MEETING.

THE next Ordinary Meeting of this Branch will be held on Tuesday, November 7th, at the Town Hall, Cardiff, at 1.30 P.M. The Council will meet at 12.30 P.M.

The Dinner will take place at 5.30 P.M.; and members may introduce professional friends to the meeting and dinner.

Members intending to read papers or notes of cases are requested to communicate the titles thereof as soon as possible to one of the Honorary Secretaries.

All members who purpose joining the dinner, will oblige by communicating their intentions to one of the Honorary Secretaries before the 31st instant.

ANDREW DAVIES, } *Honorary Secretaries.*  
ALFRED SHEEN, M.D., }

October 4th, 1871.

### SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT MEETINGS.

A MEETING of the members of this district was held at the Castle Hotel, Hastings, on Friday, September 29th. Fourteen members present, and two visitors. Dr. J. M. CUNNINGHAM of Hailsham was elected Chairman.

*Secretary.*—Dr. Trollope of St. Leonard's was appointed District Honorary Secretary in the place of Mr. Mudd of Uckfield, who resigns in consequence of leaving the neighbourhood.

*New Members.*—John Cooke, M.B., of Hastings, was elected a member of the Branch. George B. Turner, M.D., of St. Leonard's, was nominated as a member of the Association and of this Branch.

*Communications.*—1. Dr. G. MOORE of Hastings read a paper on a case of Diabetes of three months' standing. The patient had previously been rigorously dieted. Under a bread-and-milk diet (three pints of the latter daily) and the administration of effervescing salines, with iron, the urine became perfectly free from sugar in a fortnight, and the patient speedily gained flesh and strength. Dr. Moore expressed himself strongly in favour of the free use of milk in such cases.

2. Mr. G. F. HODGSON of Brighton exhibited a pair of Long Forceps with the handles curved backwards, according to the suggestion of Dr. Aveling, and claimed for his instrument its adaptation for all cases in which the use of the forceps was required.

3. Mr. BUXTON SHILLITOE of London, who was present as a visitor, explained the process of the A B C Company (of which he is a director) as now in course of application to the sewage of Hastings.

*Dinner.*—Fourteen gentlemen subsequently dined at the Castle under the presidency of Dr. Cunningham.

The next meeting will be held in November at Brighton, Dr. Alfred Hall in the chair. The Honorary Secretary requests early notice of intended communications.

## OBITUARY.

### CHARLES A. HARRIES, M.R.C.S., OF BATH.

THIS gentleman was born on February 19th, 1808. He was engaged in the practice of his profession upwards of forty years. An ardent lover of science; a man of genial and amiable disposition, ever ready with a cheering smile and kindly word; a zealous discharger of every private and public duty; he won the respect and affection of a very large circle of patients and friends. He was a town councillor of Bath for many years, and rendered valuable services to his fellow-citizens. So attached was he to his work that, although ailing for some time, he only ceased his labours a few months since, being compelled to resign his practice by the progress of cardiac disease, which ended fatally on September 22nd, 1871.

## GEORGE CURSHAM, M.D., F.R.C.P.

ON Saturday, September 23rd, full of years and honour, there passed away at the age of 75, George Cursham, M.D. Paris, F.R.C.P. Long will Dr. Cursham be mourned and his memory affectionately cherished by those who were admitted to the privilege of his intimate acquaintance. Dr. Cursham's high principle and unfailing rectitude, combined with his clear judgment, made him highly respected by his professional brethren, who must feel that one has gone forth from amongst them whose place will not easily be filled. Dr. Cursham was for many years Physician to the Brompton Consumption Hospital and to the Asylum for Female Orphans; he was also for some years Secretary to the Royal Medical and Chirurgical Society, and held up to the time of his death the post of Inspector of Anatomy to the provincial schools.

## JOHN SCOTT, F.R.C.S.ED., OF CULROSS.

It is the wish of some medical men to die in harness, but it is seldom that such is so fully carried out as in the sudden and sad death of Mr. John Scott of Culross. He went out on the morning of the 15th August apparently in good health, and had visited one or two of his patients and was on his way to see another, when he felt the first symptoms of the fatal seizure. After three such warnings he came out of his gig, told his boy not to leave him, and lay down by the road-side and died. Such was the sad end of one who, in his lifetime, gave comfort and strength to many a sufferer, and whose cheering words revived the heart of many a drooping one. He was born in Culross in 1807, and received his diploma from the Royal College of Surgeons, Edinburgh, in 1829. In 1856 he had the fellowship of the same college conferred upon him. His first intention was to join the Army or Navy Medical Service; but, through great persuasion, he consented to remain in his native place, where he successfully practised, without intermission, till the day of his death. He was the only recognised consulting practitioner in the district, and his loss will not only be felt throughout his native parish, but for many miles round.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received their certificates to practise, on Thursday, September 28th, 1871.

Dean, Stroudfield, 40, Woburn Place, W.C.  
Mountaine, John, Wile's Hall, Sunday's Well, Cork

The following gentlemen also on the same day passed their first professional examination.

Bennett, William, Edward, Guy's Hospital  
Evans, John, London Hospital  
Nix, Edward James, Charing Cross Hospital

At the Preliminary Examination in Arts, held at the Hall of the Society, on the 29th and 30th of September, 1871, 159 candidates presented themselves; of whom 66 were rejected, and the following 93 passed, and received certificates of proficiency in general education; viz., in the First Class, in the order of merit.

1. E. J. Monbodou, 2. H. P. E. Freund, 3. A. C. Routh, 4. A. S. Eccles, 5. C. Hayward, 6. Nicholls, and H. C. Taylor. 8. H. R. H. Bigg, P. S. Edwards, 1. G. Hayes, P. Hookham, J. L. Jacquet, W. B. Johnson, R. D. Perry, and Thomas Tomlinson. 16. J. R. Blackie, L. Druiet, C. G. Emson, E. Ground, A. G. Lucy, Stephen M. Smith, and J. Wishaw.

In the Second Class, in alphabetical order.

L. M. Anderson, P. W. Asher, H. Baker, Henry Bartlett, T. A. Bell, J. S. Biale, George S. R. Bigg, Archibald Blair, H. Blake, G. C. Bouton, G. R. Bonsall, A. L. Bowen, C. J. L. Bowling, Francis W. Brown, Thomas L. Brown, A. H. Burton, H. C. Burton, G. W. Butler, W. F. Campbell, G. R. Chadwick, E. T. Chamberlain, H. B. Crofts, Edmund Da Costa, H. E. Daniell, A. M. Davies, H. P. Denning, D. W. Ferguson, William Forestry, E. G. Francis, Walter Gray, W. H. George, G. W. Hambleton, Howard Harris, A. Harding, W. K. Hatch, Alfred H. Gunn, C. A. Holmes, Reginald Humphry, Robert Bennett James, William Jones, N. T. King, J. Tomlinson Knight, J. L. Lampany, S. E. H. Lane, Leon Lawson, Joseph Lewis, E. H. MacLaughlin, D. D. Malpas, W. H. Massey, Ernest Martyn, Joseph W. Moore, T. C. Mughlton, Richard Pinnell, J. H. Pinnell, P. A. Pugh, R. R. T. Riek, Alanzo Roberts, John T. Roberts, Harvey Rogers, G. F. H. Rule, W. Schellfield, Richard Steele, John J. Stephenson, John G. Swaine, John Symonds, John Thomas, Henry Thomas Tomlinson, Charles P. O. Townsend, Ethelbert Wade, Austin George Ward, and Arthur Francis Wilson.

## MEDICAL VACANCIES.

The following vacancies are announced:—

ATHAM UNION, 1000—Medical Officer for the St. Mary's District ASYLUM FOR FEMALE ORPHANS—Physician.  
BALLINARLOE UNION, 1000—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Lanesborough Dispensary District.

BALTINGLA UNION, co. Wicklow—Medical Officer for the Kiltegan Dispensary District.  
BRISTOL, City of—Medical Officer for District No. 2.  
CAHERCIVEEN UNION, co. Kerry—Medical Officer for the Emlagh Dispensary District.  
CHARING CROSS HOSPITAL—Assistant Physician.  
CLAPTON—Divisional Surgeon to the Police.  
CORNWALL LUNATIC ASYLUM, Bodmin—Assistant Medical Officer.  
DORCHESTER UNION—Medical Officer for the Dorchester District and the Workhouse.  
GUEST HOSPITAL, Dudley—Resident Medical Officer.  
INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, Margaret Street, Cavendish Square—Visiting Physician.  
LIVERPOOL NORTHERN HOSPITAL—House-Surgeon.  
MARLBOROUGH UNION, Wilts—Medical Officer for District No. 2.  
MAYO INFIRMARY, Castlebar—Surgeon.  
OMAGH UNION, co. Tyrone—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Eastern Division of the Omagh Dispensary District.  
PEMBROKE UNION—Medical Officer for District No. 5.  
POCKLINGTON UNION, Yorkshire—Medical Officer and Public Vaccinator for the Pocklington No. 2 District and the Workhouse.  
RATHDOWN UNION, co. Dublin—Medical Officer for the Killiney Dispensary District.  
ROMFORD UNION, Essex—Medical Officer for District No. 7.  
ROYAL COLLEGE OF SURGEONS, England—Member of Council.  
ROYAL INFIRMARY, Edinburgh—Resident Physician, Clinical Wards.  
ST. LEONARD'S SCHOOL, Brentwood—Surgeon.  
TIVERTON UNION, Devon—Medical Officer for the Silverton District.  
WARMINSTER UNION, Wilts—Medical Officers and Public Vaccinators for the Corsley and Warminster Districts and the Workhouse.  
WARRINGTON, Lancashire—Medical Officer of Health.  
WESTHAMPTON UNION, Sussex—Medical Officer for the Rumboldshyke District.  
YORK COUNTY HOSPITAL—House-Surgeon.

## MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.*

ANDREW, R. W., L.K.Q.C.P.Irel., appointed Medical Officer for the Palmerstown Dispensary District of the South Dublin Union.  
CULLEN, Owen, L.K.Q.C.P.Irel., appointed Medical Officer for the Kilmeaden Dispensary District of the Waterford Union.  
\*Low, Robert Bruce, M.D., appointed Medical Officer and Public Vaccinator for the Messingham District of the Glanford Brigg Union, Lincolnshire, *vice* W. Terwest, M.D., resigned.  
STRAFFORD, Thomas, Esq., appointed Resident Surgeon to the Worksop Dispensary, *vice* Edward J. Cooke, M.B., resigned.

## BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.*

## BIRTHS.

SCOWCROFT.—On October 3rd, at Bolton-le-Moors, the wife of \*J. Edwin Scowcroft, L.R.C.P. Ed., of a son.  
SIBBALD.—On September 29th, at 16, Dalrymple Crescent, Edinburgh, the wife of \*John Sibbald, M.D., of a son.

## DEATHS.

BAIN, John, Esq., Surgeon, at Johnstone, N.B., aged 27, on September 22nd.  
MORGAN, John Flower, Esq., Surgeon (formerly Assistant-Surgeon and Royal Lancashire Militia), at Bath, aged 86, on September 23rd.  
PANTON, George, Esq., Surgeon, at Dorchester, aged 55, on September 26th.

THE EAST RIDING OF YORKSHIRE LUNATIC ASYLUM at Beverley, which has been erected at a cost, including land, and fitting and furnishing, of nearly £40,000, will be opened in a few days.

MR. EDWARD SMILES, M.R.C.S.ENG., of Alnwick, is a candidate for the Coronership of Northumberland, vacant by the death of Mr. Hardy.

VACCINATION PROSECUTIONS.—At the Orsett petty session, John Whitmore, a labourer, was summoned for having neglected to have his two children vaccinated, and he was ordered to have it done forthwith.

RELEASE OF MR. WILSON FROM CRICHTON ASYLUM, DUMFRIES.—The *Liverpool Mercury* states that Mr. Thomas Wilson, of Harold Tower, Isle of Man, whose recent confinement in the Crichton Asylum, Dumfries, has caused so much comment, has been released, and arrived at his home in Douglas on Friday night, last week.

BEQUESTS, ETC.—Mr. William Welch of Great Brook Street, Birmingham, has bequeathed £300 to the General Hospital, £300 to the Queen's Hospital, £200 to the Children's Hospital, and £200 to the Homoeopathic Hospital.—Miss Carter of Lynn has bequeathed £300 to the West Norfolk and Lynn Hospital.—Mr. John Palmer has bequeathed £100 each to the General Hospital, Queen's Hospital, and General Dispensary, Birmingham.—Mr. J. Nutter of Halifax has given £500 to the Bradford Infirmary.—Miss Rosa Ann Long of Dawlish has bequeathed £100 each to the Devon and Exeter Hospital, the Dawlish Dispensary, and the Brompton Hospital for Consumption.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY** ..... Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**TUESDAY** ..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**WEDNESDAY** .. St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**THURSDAY** .... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**FRIDAY** ..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.

**SATURDAY** ... St. Thomas's, 9.30 A.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**WEDNESDAY**.—Hunterian Society. 7.30 P.M., Council Meeting. 8 P.M., Introductory Address by the President; and a paper by Dr. Daldy.

**FRIDAY**.—Clinical Society of London, 8.30 P.M. Dr. Christian Bäumler, "On Cases of Partial and General Idiopathic Pericarditis"; Dr. Anstie, "Conclusion of a Case of Syphilitic Neuralgia, which was reported last Session", and "On a Case of Anæsthetic Leprosy"; Mr. Nunn, "On a Case of Scrofulo-derma treated by Woodhall Water"; Mr. George Lawson, "On the Treatment of a Case of large Melanotic Tumour of the Eye extending into the Orbit."

## NOTICES TO CORRESPONDENTS.

**ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.**

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**TO PURCHASERS**.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with *halfpenny* stamps for the amount.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

**WE** can only advise Mr. Rae to communicate privately with the gentlemen whom we have mentioned; and if he finds encouragement enough, we shall be happy to see him personally to give him further counsel how to proceed satisfactorily in the matter. It is a matter not less delicate than important.

**MR. ERNEST TRESTRAIL**.—The drawing up of the lists for publication in the JOURNAL is in the department of the General Secretary; and Mr. Trestrail should address Mr. T. Watkin Williams, 13, New Hall Street, Birmingham, on the subject of his missing qualification.

## WASP-STINGS.

**SIR**.—Mr. Drury's remarks on the treatment of wasp-stings are very opportune at this season, as wasps are unusually numerous this year, and the present cold weather will reduce them from their flying to their crawling, and therefore more dangerous and vicious state, at an earlier period than usual.

Mr. Drury referred incidentally to the old woman's remedy of the "blue bag", but did not express an opinion on its use. I have myself so frequently witnessed its beneficial action, that I am anxious to say a few words in its favour. As a speedy application of a local remedy is of the utmost importance to prevent or modify the constitutional disturbance, and, as the surgeon can scarcely be in immediate attendance, it is desirable not to throw discredit on a popular remedy unless we are prepared to substitute an equally convenient and more efficient one in its place.

I was induced some time ago to make a rough analysis of some specimens of the "powder blue" of the shops, and I found some of them to consist of more than half their weight of carbonate of soda. This alkali is no doubt the active constituent of this old woman's remedy, and is, I believe, the one most commonly used by surgeons. The damp blue bag has the advantage of being always at hand, is easily applied, and is used with confidence by the public; while other remedies are probably not available, may require skill in their application, and are employed with doubt by the old women.

For surgical purposes, I have found the strong solution of ammonia, strong acetic acid, or strong solution of carbolic acid, the most useful; and I should expect little benefit from the application of laudanum in the first instance, though in a late stage it would allay general irritability of the skin. For this purpose, the anæsthetic action of the solution of carbolic acid is beneficial. For urgent constitutional symptoms, a much larger dose of sal volatile than that recommended by Mr. Drury may be given—a teaspoonful every fifteen or twenty minutes; but the treatment would necessarily depend on the constitution and temperament of the patient.

I am, etc.,

CHARLES ROBERTS, F.R.C.S.

Bolton Row, Mayfair, September 25th, 1871.

**NOTICE TO ADVERTISERS**.—Advertisements should be forwarded direct to the Printing-Office, 37, Great Queen Street, W.C., addressed to Mr. F. H. HEATHCOTE, not later than *Thursday*, twelve o'clock.

## "THE BUBBLE REPUTATION."

**SIR**.—"There is a pleasure in the pathless woods"; but commend me to the London streets for cheap amusement and mental relaxation. You may go further and fare worse, as the spirited proprietor of purgatory remarked to the discontented druggist. One of those vexatious elbow-joint injuries—a case of separation of the lower epiphysis of the humerus, the three points posteriorly all right, yet flexion restricted—necessitated a visit to the modern Babylon, and a consultation in Wimpole Street. In a shop window, the photographs of certain medical celebrities attracted attention. Miller, Tanner, Hyde Salter, are at rest: all fought a good fight and died in harness.

Contemplating in rapt admiration the visages of my "distinguished" contemporaries, I seem presently to become the confidant of what is going on in the frame before me. Dr. Guy here calculates the income of Sir H. Thompson, Bowman, and Spencer Wells. Henry Lee considers syphilis a joke. Farr arranges a difference between the Major and the terrific Letheby. Wilks, Pavy, and Chambers consult on a case of Ship-and-turtle-itis. Arthur Farr remarks that really he and Sir William Jenner only care to attend princesses; but Braxton Hicks, Barnes, Playfair, and Priestley are available. Druitt reads a proof of an ever welcome edition of "Surgery." Partridge tells the gigantic sphenooid story. Henry Smith "at last" (Kingsley) has caught a fish in the Serpentine, and invites John Wood to dine, to meet Sir William Fergusson. Erasmus Wilson sneers at the new skin-baths. Forbes Winslow invites every one permanently to Hammersmith. Tilt congratulates Paget on the change of life. Ernest Hart is shocked to read that in Terra del Fuego the natives believe in devils, and that they are the departed spirits of members of the British Medical Association who have not paid up their subscriptions; and Garrod tells a gouty bishop "that the gods are just, and of our pleasant vices make instruments to scourge us."

I am, etc.,

CHUTNIE CURRIE, M.D.

Cheltenham, October 1871.

## DR. PIRRIE ON ACUPRESSURE.

**SIR**.—I observed recently some remarks of Dr. Pirrie's on his favourite subject acupressure, wherein he says:—"The circumstance that obsolete modes are alone described in the last editions of otherwise excellent works on surgery, have all tended to retard the more general adoption of this new means of arresting surgical hæmorrhage." Without more than alluding to the paradox of "obsolete modes" of a "new means" of arresting surgical hæmorrhage, it would be well that Dr. Pirrie, who has the interest of students at heart, should name those editions of "otherwise excellent works on surgery" that have described only obsolete modes of acupressure. Dr. Pirrie, otherwise generally accurate in his language, uses the term *inelastic* as applied to iron wire. Such a term is used in contradistinction to *elastic*. The latter attribute is not generally given to the adamantine mineral, but Dr. Pirrie may know a kind of iron wire that is not inelastic. In case the same mistake should happen with the Aberdeen method of acupressure, as happened with Sir J. Y. Simpson and chloroform, I think it right here to mention—especially as future glory is prophesied for one now dead on account of acupressure—that although Dr. Pirrie described the method in his conjoint book, the late Dr. Benjamin Knowles was the originator of the method, and demonstrated and described it to many of his friends and classfellows, and afterwards to Dr. Pirrie and the hospital staff. As surgical appliances and methods are not commonly called after the towns in which they first saw light, I propose that the name of the method of occluding an artery in a surgical wound by a needle twisted through the surrounding tissues and over the artery, be named the "Knowles's method", the same as we have "Synie's abscess-knife" and "Pirrie's modification of Pirogoff's operation." This is a small recognition to give one now passed away, but it may prevent future confusion. I am sure Dr. Pirrie himself would regret any misapprehension of the kind. Trusting you will find space for these remarks,

I am, etc.,

A. E. MCRAE, C.M., M.B.

Fettercairn, August 1871.

## A CHARITABLE PROPOSITION.

**SIR**.—The public will learn with unmixed satisfaction that it is in contemplation to present a testimonial to Sir James Paget on his elevation to the baronetcy. It is very honourable to St. Bartholomew's Hospital that this proposal should have emanated from thence; but, sir, the scientific world, both here and abroad, recognise Sir James Paget as belonging to it, and to the profession at large; and I am well persuaded that the profession at large will endorse this recognition, if opportunity be conceded them to participate in the movement. The main question which naturally presents itself is—What form should such a testimonial most appropriately take? Passing over the familiar and well-worn expedients of a piece of plate or a portrait as less worthy emblems of a feeling like this, would it not be more in unison with the character of the recipient, as well as more distinctly expressive of their appreciation of it by the givers, if a "Paget Fund" were established in connection with the British Medical Benevolent Fund, of which Sir James Paget is already a trustee, and with the purposes of which his sympathy has been unmistakably evidenced, in order to found for ever one or more annuities for the support of aged and destitute members of the profession or their widows, to be chosen from the most deserving and necessitous in the same careful manner in which the other annuitants, supported by that institution, are at present selected, or in any other way Sir James might himself suggest?

Will you permit me, through your valuable aid, to submit this for general consideration? and whether it would not for all time enhance the honour we desire "to render to whom honour is so justly due"—to identify with it a help in need to the less successful of our brethren in the race of life?

October 2nd, 1871.

I am, etc.,

H. F. S.

## AMERICAN DEGREES.

**SIR**.—Would you inform an associate through the BRITISH MEDICAL JOURNAL, if a Degree of Medicine and Surgery from the Medical College, New York, entitles the party possessing it to style himself M.D. and Surgeon; and if he can legally practise medicine and surgery without fear of prosecution under the Medical Act; and if a Philadelphia Degree is of an equal status? An answer in your next issue, or at your earliest convenience, will very much oblige.

Newcastle-on-Tyne, Sept. 27th, 1871.

I am, etc.,

MEDICUS.

\* \* On inquiry, we expect both would be found to be bogus Colleges, and worthless degrees. Neither degree is registerable. Our correspondent should address his query, with full particulars, to the Registrar of the General Medical Council, Soho Square, W.C.

**NOTICES of Births, Marriages, Deaths, and Appointments, intended for insertion in the JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.**

#### NITRATE OF AMYL AS A REMEDY FOR CHOLERA.

SIR,—In your JOURNAL of the 30th ultimo, Dr. Talfourd Jones suggested the use of nitrate of amyl "in the collapse and cramps of cholera." As he appears to think the suggestion has not been made before, he will be interested in learning that I published a like suggestion in 1866. At page 208 of the second edition of my work on *Diarrhoea and Cholera*, published in that year, is a paragraph headed "Nitrate of Amyl." In that paragraph will be found the following words: "This substance possesses a very remarkable quality, which has led me to hope that it may prove of great value as a remedy for cholera." And, again, after stating that "the circulation of the blood is rapidly increased to an astonishing extent" by holding to the nostrils the tip of a feather dipped in the nitrate of amyl, I add: "Its remarkable property of increasing the circulation in the rapid and astonishing manner described, causes me to think that it gives greater promise of acting as an antidote to cholera than any other medical substance yet known. I much regret that, as yet, I have had no opportunity of trying its efficacy; and I hope that those physicians who have charge of cholera patients will carefully test its value." London, October 3rd, 1871. I am, etc., JOHN CHAPMAN, M.D., M.R.C.P.

#### OVARIOTOMY.

SIR,—This operation is now becoming so common that I should not attempt to occupy either your time or space with its consideration had I not seen Mr. Russell's case reported in your impression of September 23rd. The report states that "the woman was dressed with lint soaked in equal parts of carbolic acid and glycerine.... during the after part of the day of operation, the patient complained of very acute abdominal pain, for which opium was administered freely by the rectum in the form of tincture, and suppository combined with belladonna, but without alleviation. Hypodermic injections of morphia quickly gave relief, and they were repeated twice or thrice daily for ten days."

I have myself used carbolic acid as a dressing for some time. At first, my anxiety prompted me to use what I now call a strong preparation—carbolic acid one part, glycerine two parts, and water five parts; and the result was such as Mr. Russell has recorded—"acute abdominal pain," though in a less degree, not calling for the hypodermic injections of morphia two or three times daily for ten days. I have found a suppository of 15 grains of compound soap pill, two or three times repeated, sufficient to control the pain. I am therefore disposed to think that the dressing in Mr. Russell's case had something to do with the production of the "acute abdominal pain." In my last case, operated on July 10th, assisted by Drs. Barnes and Aveling, and Mr. M. W. Chambers, I used as a dressing carbolic acid one part, glycerine two parts, tincture of opium four parts, water to forty parts. Lint soaked in this compound was placed over the wound as soon as closed, and kept on by adhesive plaster, over which was placed a thick layer of cotton wool, and secured by a flannel bandage and carpet pins. A suppository was passed into the bowel, and the patient put to bed. She was much exhausted; pulse 150; no pain beyond the smarting in the wound, which passed off in a few hours. The dressing was repeated every morning; perfect union by the first intention by the fifth day; no smell or discharge from the first. This form of dressing is simple, clean, sedative, antiseptic, light, and sufficient under ordinary circumstances. I regard opium as a valuable adjunct to carbolic acid as a dressing for such wounds. Should Professor Lister's views be correct as set forth in his address at Plymouth, cotton-wool will ere long hold an important place in the "bag" of every ovariotomist. In my case, the whole abdomen, from the upper part of the thighs to the breast, was thickly covered with it, and the result was most satisfactory. The wound was perfectly united on the fifth day, several days before Mr. Lister's address was delivered. Perhaps I may state that in this case the disease had been slowly progressive for upwards of four years; that the weight of the tumour when removed was thirty-two pounds; that the powers of life, from the combined influence of pressure, sleeplessness, and constant vomiting, had been reduced to a very low ebb. In order to show that it was not a specially favourable case selected for the illustration of any special form of treatment, the chief articles of diet were milk, eggs, and mutton, with the smallest possible quantity of stimulants; one grain of quinine, three times daily, from the first, with twenty grains of chloral hydrate at bedtime every night, were all the medicines resorted to throughout. I am very strongly inclined to the opinion that the less we dress and physic ovarian cases, the better the results. Apologising for troubling you at so great length, I am, etc., THOMAS CHAMBERS, F.R.C.S. Ed. 2A, Sutherland Street, S.W., September 1871.

#### PREPARE OF BROMIDE OF POTASSIUM.

DR. JULIUS LEON, of Berlin, writes:—In private and public practice I have frequently used for a long time saturated bromide of potassium in drachm doses or more three times a day. If continued for months, it is apt to produce (as I believe) a series of boils. If I observe, it is far from being a preparation of ichthene has given with the bromide, I have then never seen any boils or other evil sequelae arise.

#### GRATITUDES TO VACCINATORS.

SIR,—I see in the JOURNAL of to-day, at page 419, mention of Government Gratitudes to Public Vaccinators. Would you kindly let me know how such gratuities are to be got, as I have been lately appointed Public Vaccinator to this district? September 1871, etc., VACCINATOR.

\* By direct instruction to the Board for Vaccination of the Medical Department of the Local Government Board, and by careful vaccination, so as to show good "results."

THE TOWN OF BARNET.—This township, which was referred to in our issue of August 19th, has been so successful in its efforts to secure the establishment of a public library in London, and that a Committee is being formed to lay the matter before the public and the profession. In the mean time, we are glad to mention that Dr. Percy Bland, in answer to a circular issued several years ago of the patients of the late Dr. Taylor, has received sums amounting to £1,000.

#### THE LANCET'S TESTIMONY ON THE PHOSPHORUS.

SIR,—Can you find any traces, either in the columns or pages, of the LANCET, of the testimony given by the public body of the British Phosphorus (1867)? If so, would be pleased to be informed of it, or, if not, in putting it into the hands of a person or persons, it will be very much obliged. If he separated his contributions either of money or of publishing, did he get the same thing, or anything like it? I am, etc., A. SLOAN.

DR. EDMUNDS' letter shall appear next week. It is somewhat lengthy, and he will observe that our space is this week subject to great pressure.

#### UMBILICAL EXCRESCENCE IN AN INFANT.

SIR,—A case similar to the one related in the JOURNAL of September 23rd, occurred in my practice a few months ago. The child, a healthy one, three years of age, had suffered from its malady since it was fifteen months old, and the mother assured me there had been more or less bleeding every day. It was bleeding freely the first time it was brought to me.

Having applied such remedies as I thought suitable for the case—viz., nitrate of silver, perchloride of iron, etc.—but without avail, I resolved to tie a ligature round it. The growth came off on the fourth day. It required no further interference; and there has not been the slightest inconvenience since that time.

I am, etc.,

J. EDWIN SCOWCROFT, L.R.C.P. Ed., etc.

Bolton, September 26th, 1871.

#### THE O. W. FUND.

SIR,—Having only just seen, since my return from France, your kind corroboration of a letter addressed by my friend Dr. Lavies to the *Medical Times and Gazette*, on my behalf, I beg you will allow me, through your JOURNAL, to express my gratitude to all those contributors whom, through ignorance of their names and addresses, I have not been able to thank either personally or by letter.

September 26th, 1871.

I am, etc.,

O. W.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Gateshead Observer, Sept. 30th; The Bath Chronicle, Sept. 28th; The Birmingham Morning News, Oct. 2nd; The Liverpool Albion, Oct. 2nd; The Weston Mercury and Somersetshire Herald, Sept. 30th; The Bradford Observer, Sept. 30th; etc.

#### COMMUNICATIONS, LETTERS, ETC., have been received from:—

Mr. F. Le Gros Clark, London; Dr. H. Charlton Bastian, London; Dr. William Carter, Liverpool; Mr. A. Allen, Sheffield; Dr. Markham, London; Dr. Orton, Beeston; Dr. G. H. Philipson, Newcastle-upon-Tyne; Dr. Basham, London; A Member; Mr. H. E. Armstrong, Newcastle-upon-Tyne; Mr. R. S. Fowler, Bath; Dr. J. H. Aveling, London; Dr. Edmunds, London; Dr. G. M. Brumwell, Mossley, Manchester; The Secretary of the Royal Medical and Chirurgical Society; Dr. Percy Boulton, London; Mr. Arthur Andrews, New Southgate; Mr. John Morgan, Waters Upton, near Wellington; Mr. Rushton Parker, Liverpool; The Registrar-General of England; The Secretary of Apothecaries' Hall; The Registrar-General of Ireland; Mr. T. M. Stone, London; The Registrar of the Medical Society of London; Mr. G. F. Hodgson, Brighton; Dr. B. W. Foster, Birmingham; Mr. Henry Lock, Dorchester; Dr. John Chapman, London; The Secretary of the Medical Council; Dr. Rutherford, London; Dr. A. Meadows, London; Dr. Little, London; Dr. F. J. Brown, Rochester; Mr. Jabez Hogg, London; Dr. Brown, Coventry; Dr. Thos. Chambers, London; Mr. Christopher Heath, London; H. F. S.; Dr. Green, London; Surgeon-Major Atchison, Tenby; Dr. Taylor, Cardiff; Mr. H. H. Spencer, Clifton; Dr. Julius Levy, Berlin; A Vaccinator; Dr. W. Erskine, Kincardine; Dr. Hogg, Royal Artillery Institution; Dr. Chadwick, Leeds; Mr. Wheelhouse, Leeds; Mr. Knipe, Melbourne, Derbyshire; Mr. Dawson Turner, D.C.L., Liverpool; Mr. Jessop, Leeds; Mr. Charles Roberts, London; Dr. Daniel Moore, Upper Norwood; The Secretary of the Clinical Society; Dr. Barkas, Newcastle-upon-Tyne; Mr. C. S. Welber, London; Dr. Russell, Birmingham; Dr. Siordet, Mentone; Dr. Styrup, Shrewsbury; Dr. Nankivell, Torquay; Mr. A. W. Tomkins, Leamington; Mr. Ernest Trestail, Harston; Mr. A. W. Nankivell, Rochester; Dr. A. Wynn Williams, London; Dr. A. E. M' Rae, Fettercairn; Dr. T. H. Green, London; Our Manchester Correspondent; etc.

#### BOOKS, ETC., RECEIVED.

## CLINICAL LECTURE

ON THE

## PROPER CHOICE AND ADJUSTMENT OF TRUSSES.

*Delivered at King's College Hospital, May 25th, 1871.*

By JOHN WOOD, F.R.S.,

Surgeon to the Hospital, and Professor of Surgery at the College.

GENTLEMEN,—In the practice of your profession you will find that the sort of practical knowledge which I propose this day to inculcate is that of the most useful, and even necessary, kind. Not only will it be useful to those whose comfort and lives will be in a considerable measure dependent upon your knowledge and care, but it is also necessary, in the present day, to insure your passing your examinations for legal qualification; for it will not only be incumbent upon you, as medical practitioners, to diagnose that your patient has a rupture, and that his ailment is not really one of the many which may resemble closely, and be mistaken for, that disease, and which would be made worse by wearing a truss. It will not be sufficient for you to say to your patient, "You must go to so and so, an instrument-maker, and get a truss." To do your duty by him you must know what kind of truss he should wear, and ascertain whether it is properly fitted, thoroughly effective, and suitable for the kind of rupture with which you have to deal. Too commonly all this kind of care is committed, without check, to the instrument-maker, who may be guided entirely by a mechanical rule of thumb, or may be interested in getting sold a particular kind of truss, in which he has an interest as a matter of business, and which gives him the least trouble in fitting, as expeditiously as if it were a pair of ready-made shoes. If your fortunes place you in a part of the country where trusses are not easily obtained, and your patient cannot leave his home, you may be required to decide not only upon the shape and strength, but to take the proper measurement of the truss which he is to wear. Like every other sort of professional knowledge, this must be obtained beforehand, perfected and put by for use, while your anatomical skill is still fresh and ready to hand. Now in a truss there are two principal parts which require separate consideration; viz., (1) *the pad* which communicates the pressure directly upon the hernial opening and restrains the protruding tumour; and (2) *the retaining apparatus* which holds the pad in place, and applies and distributes the pressure and counterpressure. In the great majority of instances the varieties of each of these may be combined, in various ways, with those of the other; and you are not obliged to employ a particular kind of compressing apparatus with a particular kind of pad. In my opinion, the choice of the shape and material of the pad, and its adaptation to the kind of rupture, is of more importance than the kind of apparatus which is contrived to keep it in its place. This arises from its more intimate relation to the constituent parts of the rupture. I have elsewhere explained to you that in reference to the means of relief—*i.e.*, in their practical aspect—ruptures may be divided (1) into those in which the opening in the abdominal walls is oblique or valvular, and more or less tubular, and (2) those in which it is direct and short. Again, an important consideration is whether the hernial opening normally transmits, or is in close relation to, important structures, which must be protected from any injurious pressure or other damage. Now the *oblique* or *external* inguinal hernia is usually valvular; and it is also, in the male, in close relation with the delicate structures composing the spermatic cord. The *femoral* or *crural* hernia is less effectively valvular in its formation, and it is also in close relation to the large and important femoral vessels and lymphatics. In these kinds of rupture, especially, the size and outline of the pad should correspond pretty nearly to that of the valvular hernial canal when at its greatest point of distension. In large inguinal ruptures which descend into the scrotum, and in those of the crural variety, which finally pass upwards and outward over Poupart's ligament, this shape will correspond to that of the neck of the sac when fully distended. The form of such outline, with all the angles rounded off, will be usually an oval, elliptical, or egg-shape—sometimes wider above at the deeper hernial opening, and sometimes wider below at the more superficial of the hernial apertures; but most frequently, in oblique inguinal ruptures, widest in the middle opposite the dilated canal.

In ruptures of the direct non-valvular kind, such as the direct inguinal, umbilical, ventral, and some others, of which, being uncom-

mon, I have scarcely opportunity on this occasion to treat, the opening is usually either round or oval; in the latter case, the long diameter is more or less vertical, usually, in the direct inguinal and ventral varieties, and more or less horizontal in the umbilical variety.

Next, the shape of the surface of the pad which is placed on the skin is important. To understand properly the force of my remarks upon this point, it will be necessary to recall to your minds the shape and other peculiarities of the different hernial openings. In oblique inguinal hernia we have the deeper opening, oval or round in shape, placed external to, and somewhat above, the superficial one; or, to be more precise, a little above, and internal to, the centre of Poupart's ligament. The superficial opening is bounded laterally by two strong bands of aponeurosis, the inner and outer pillars of the ring; and these are held together, more or less strongly, at the upper part of the intercolumnar or arciform bands, which convert its otherwise triangular shape into a more or less elongated ovoid. Placed behind this opening is the conjoined tendon of the internal oblique and transversalis muscles, blended with the fascia transversalis and the triangular aponeurosis; forming internally the sheath or covering of the rectus abdominis muscle, the outermost part of the lower tendon of which is placed opposite to, and covers behind, the lower end of the superficial abdominal ring. Now, these united fasciæ form the deeper side of the valvular arrangement of the inguinal canal, by the forward pressure against which, exercised by the abdominal contents when compressed by the diaphragm, transversalis, and rectus muscles, the canal is shut up by contact with the external oblique tendon, and closed against the protrusion of the viscera in the normal condition.

In the truss treatment of oblique inguinal rupture, we meet with an instrument such as the one I show you, which presses, by means of an elevated and highly convex pad, the superficial wall or coverings of the rupture deeply into the abdomen, carrying the hinder wall before it, and depressing all these tissues into a cup-shape, with its highly convex exterior outline turned towards the abdominal cavity. The inevitable effect of this is to open up the superficial aperture, to stretch, spread out, and weaken, the fascial textures, and to destroy the valvular action of the deeper or hinder wall of the canal by inverting its normal curve. A rupture which has been subjected long to such a pressure inevitably becomes larger in process of time, although it may never be suffered to descend. Its hernial openings have, in fact, been enlarged by the plugging action of the truss-pad constantly exerted upon it, in the same way, though inverted, as the pressure made from within by an unreduced rupture.

In the region of crural hernia, the deeper opening or crural ring is placed almost horizontally, while the superficial one—the saphenous opening—looks forward, and a little inwards and downwards, both being in shape more or less round or oval.

The anterior wall of the crural canal is very short, and is formed by the union of the femoral sheath with the band of fascia lata, constituting the so-called Hey's or femoral ligament, continuous with the upper horn of the saphenous opening. The hinder wall is longer, and is formed by the femoral sheath, supported by the pectineus muscle and pubic portion of the fascia lata. Here there is no true valve-action resisting protrusion of the abdominal viscera; but, in hernial conditions, the front wall may be pressed against the hinder wall by a well-fitting truss, so as to afford a sort of substitute for such an action. Here, again, if the truss-pad be highly convex, and press into the saphenous and crural openings with anything like the force sufficient to keep up a rupture, it gradually forces more and more open the hernial apertures, and causes the rupture to become larger and larger, even when it does come down.

In direct inguinal, and also in umbilical and ventral ruptures, the hernial opening is a direct and immediate communication with the abdominal cavity, and is covered only by skin and some layers of yielding fascia, which constantly give way before the pressure of the bowels.

By the use of truss-pads, which press into this opening as a cork does into the neck of a bottle, the aperture, being elastic and yielding, is of necessity made larger and larger by the constant inward pressure of the pad. Hence arises the common complaint of patients that, in spite of the constant use and careful adjustment of the truss, the rupture, instead of becoming cured by the closure of the opening, becomes larger, and requires a larger truss-pad each time a new one is required.

*Outline and Surface of the Pad.*—The best kind of surface to prevent this inward plugging of the cutaneous tissues into the hernial opening is one of which the general surface is flat. Of course I do not mean that the edges are not to be well rounded off, but only that the bearing should be level at the sides, and rather more resisting there than in the central axis.

In oblique inguinal hernia, the shape of the neck of the rupture, where the tumour is lost in the abdominal wall, is more or less moulded by

the form of the inguinal canal, and assumes a somewhat cylindrical shape, sometimes increasing in diameter towards the upper or lower opening, so as to be of a funnel-shape, and not unfrequently becoming dilated in the middle of the canal, in cases which have remained in the condition of a bubonocoe for some considerable time.

The best general outline of pad to meet and retain this is an oblique oval, which should be large enough to overlap the limits of the dilated canal for at least half an inch each way. In this kind of hernia, in the male subject, I prefer a pad of a horseshoe-shape, in which a cleft or opening is made at the lower end of the oval large enough to allow the spermatic cord and pubic spine to lie in it, and thus escape compression. From the loose nature of the attachments of the cord at this point it readily adjusts itself to the chink in the truss, and the ends of the horseshoe lie on each side of the pubic spine, and embrace the hernial opening like the fingers of a hand. For direct inguinal hernia I prefer an ovoid or rounded pad, which has a depression or hole in the centre, to insure against any plug-like action. The bearing of this pad, therefore, is like that of a ring placed upon the body and overlapping the hernial aperture half an inch each way. The same ovoid shape, modified by placing its long axis in the same direction as that of the hernial opening, I use also in umbilical hernia. But, it may be objected, this opening in the pad will permit the rupture to pass into it, and so fail partially to retain it. Experiment shows, however, that with a hole so small, and with margins so broad pressed upon the skin and covering the tissues, the latter are kept stretched across the aperture in the muscles and tendons beneath them so firmly that no escape or protrusion whatever can take place through it.

For femoral hernia, I use a pad which is shaped to the anatomical peculiarities of the saphenous opening and crural ring. It is of an egg-shape, with the long diameter vertical and the broader end uppermost. The lower end is sloped off on its bearing surface more than the upper, which latter is intended to bear upon the crural ring, through which the rupture first descends.

*Material of the Pad.*—This is a matter of much importance, and must vary according to the sensitiveness of the patient or the object sought after. Most patients, after trial, prefer a smooth and even pressure from a hard yet somewhat elastic substance like ivory or vulcanite. If the object be a radical cure, which is sometimes to be obtained by truss-pressure, a hard firm pressure is essential. For the cheaper kinds of truss, boxwood is a good material. Like ivory and vulcanite, it can be washed and rubbed daily, and kept free from the dirt and irritating matters accumulated by perspiration. Ivory, vulcanite, or metal silvered over, is usually the most cleanly and comfortable substance to wear constantly next the skin. But some patients cannot bear this hard pressure. For such cases a soft pad must be used, such as the substance called "moc-main", enclosed in soft wash-leather; or, better still, a water- or air-pad made of India-rubber, and covered with silk or wash-leather. These substances have the merit of ready and even adjustment to the shape of the resisting tissues, and a more effective adaptation. They should, however, be prevented from assuming the shape of a cone or plug, by being fastened down or depressed in the centre, or near the lower end of the oval, so as to give them a ring or horseshoe bearing.

For umbilical and some forms of ventral rupture, a cylindrical piece of vulcanised India-rubber, bent round into an ovoid ring, and the aperture covered on the side next the skin by a thin membranous piece, answers very well. The pressure is thus made upon the margins of the hernial aperture, fulfilling the double purpose of preventing the escape of the bowel through the opening, and of tending to close the aperture through which the rupture escapes. They thus become a more efficient means of curing the rupture, as well as a means of restraining protrusion.

*The Retaining Apparatus.*—To keep the pad in its place and to maintain a proper amount of pressure, two chief means are used; viz., the side-spring and circular strap or elastic bandages. Of these it may be said that some modification of the former has been found most useful or essential in inguinal and femoral ruptures, while the latter are most used, and are certainly most generally applicable, in umbilical and ventral ruptures.

Again, there are two kinds of side-springs in use. The more common one passes round the body for four-fifths of its circumference, one end pressing upon the centre of the pad, and the other being continued by a strap which is fast to a stud placed at the middle, upper, or lower, end of the pad. In the other kind, the spring (used by Salmon and Ody) passes rather more than half round the body, bearing behind upon the spine by means of an oval or circular padded disk which carries the counterpressure. In the first kind, the counterpressure is borne by the whole of the back portion of the spring girdle. In Salmon and Ody's application the side-spring is placed on the side opposite to the rupture,

and passes across the median line in front of the abdomen to reach the hernial protrusion, to which it is supposed to give an upward and outward, as well as a backward, push. This sort of direction of the pressure may, however, be given equally by the all-round spring, and depends upon the modification of the adaptation of the curve of the spring to that of the body. Many patients find the crossing of the body by the spring in front to be an objection: this, however, is in some cases the best kind of spring to wear.

The all-round spring, in a single rupture, should reach for three-fourths of the way round the pelvis, the remaining fourth being occupied by the strap which connects the free end of the spring with the pad. It should have a level and even bearing round the hips, on a level behind with the anterior superior iliac spines, which corresponds roughly with the upper border of the gluteus maximus muscle. In the median line behind it should rest evenly upon the muscles, covering the upper part of the sacrum above the level of the posterior superior spinous processes of the ilia. It will then fall into the deep groove which is formed between the trunk and spine when the patient sits down, and will not be pushed up or depressed by the more frequent and usual changes of position between sitting and standing. Its end should neither stick into the patient's body nor project too much outwards.

A double truss, with a pad at both ends, is more likely to retain its position equally than a single one, by reason of its double bearing and increased hold upon the body. It is, for this reason, usually more comfortable also to wear. In all cases, therefore, in which a suspicion of, or tendency to, rupture exists on both sides, a double truss should be worn; and it would be well, on account of the frequency with which a rupture on one side is followed by one on the other side also, if a double truss were worn more frequently than is usually the case.

Now there are two practical difficulties in the proper fitting of a truss, which are very much increased when the patient is at a distance from the instrument-maker, and cannot be seen and fitted a few times in the process of manufacture. One is, to adjust the degree of force in the spring to that exerted by the abdominal muscles in forcing out the rupture: this varies in each individual, according to his muscular development and the resistance still offered by the hernial apertures; and varies even in the same individual under ordinary and extraordinary necessity for muscular exertion. The other is, the difficulty of getting the exact measurement and conformation of the patient's body.

The first difficulty is usually grappled with by the maker on the old principle of the "rule of thumb", from data imperfectly ascertained by

Fig.—Pressure-gauge for Hernia.

the degree of resistance to his muscular sense. This cannot, however, be communicated by the patient or his medical attendant from a distance. Attempts to do so usually terminate in lamentable failure. I have been enabled, by means of a pressure-gauge made for me by Matthews Brothers (Fig.), to ascertain to a nicety the force exerted by the rupture

both on ordinary and extraordinary occasions, and to measure in pounds weight the force of the rupture.

The instrument consists of a clamp on the principle of the Signoroni's compress, with two arms turning on a hinge, and moved by a screw. The gauge is placed horizontally like a truss upon the patient, on the side of the rupture. The hinder arm terminates in a pad which fits upon the sacrum; and the front one carries a cylinder, in which a piston is acted upon by a spiral spring, and carries, upon a ball-and-socket joint, a pad to rest upon and cover the hernial aperture. A vernier marks upon the outside of the cylinder the force in pounds and ounces required to hold in the rupture. An exact measure of strength can thus be sent for the guidance of the instrument-maker.

If the ordinary avocations of the patient do not call for occasional great exertions of muscular power, one truss, the strength of which is enough to retain the rupture under the greatest likely pressure, is sufficient; but if, as often occurs in the labouring and more active classes of society, the work of the patient be apt to call frequently for great efforts, the best way is to have a working truss of greater power, and also an ordinary truss, of less but just sufficient power, to wear when at home and in comparative rest. Attempts to combine the two by means of an additional or *rider* spring or a thicker pad, and thus to increase the pressure of the front end of the side-spring upon the rupture, are apt to fail, if the force of the intermitting exertion be very much greater than the ordinary power exerted by the patient. If it be not so, a truss can be made and worn comfortably, to meet successfully the occasional as well as the usual force. In all such cases, previous preparation must be made to meet a force which frequently comes unexpectedly and without warning.

To meet the last mentioned difficulty in fitting a truss, the measurements must be made with great accuracy and completeness, and upon a well conceived and simple plan. According to the variations in the conformation of the pelvis and hips, the position of the hernial aperture in inguinal and femoral rupture varies in relation to the sacrum and wings of the innominate bone. This is especially the case in femoral hernia, which is notoriously more difficult to fit and retain than the inguinal variety. First of all the girth of the hips, beginning and ending at the rupture, and carrying the measuring tape round the pelvis just below the level of the superior iliac spines, should be carefully made, and repeated once or twice for the sake of accuracy. (See Fig. 1, along the line *a, c, d*). Thirty-six inches is the medium girth, thus taken, in the adult male; and thirty-seven inches in the female. The limits of variation in either direction are usually about two inches. Then the distance of the middle of the hernial aperture (at *c*) from the most prominent part of the lateral aspect of the hips (at *a*) should be taken along the line *a, c*. This will differ with the stoutness and muscularity of the patient, and especially with the development of the

of the twist necessary to be impressed upon the spring in order to give the pad a flat bearing and the disposition best adapted to resist the downward pressure of the rupture, a piece of string, with a plummet or bit of lead attached to it, should be held by the patient, suspended from the level of the line connecting the spinous processes of the ilium, directly above the point of rupture (at *a*, Fig. 2). The distance at which the plumb-line hangs from the surface of the body at the point of rupture (at the line *b, c*), measured by the surgeon, will give the amount of projection of the abdomen and the slope of the surface upon which the pad must rest.

In difficult cases of double rupture, where there is a tendency for the hernia to escape on the inner side of the pads, I have found the best results from the use of a cross-strap made of an arch of steel, and fastening upon the stud of each pad, instead of a leathern strap. This brings the power of both ends of the spring to bear upon each pad, and combines the forces into a complete and powerfully resisting circle of steel.

In some difficult single cases of large direct hernia, a similar arrangement may be brought to bear upon the single pad on the ruptured side, or, in other very large cases, upon a twin pad, both halves of which bear upon the hernial opening.

Some cases will do better with a spring the curve and play of which is so constructed that it does not press inward upon the abdomen beyond its normal surface, while it effectually resists any outward impulse or elevation of that surface.

In large cases of umbilical or ventral rupture in corpulent adults, three girth-measurements should be taken—viz., one opposite the centre of the hernial opening, another at the upper part of the projecting abdomen, and a third round the loins at the same point where the all-round measurement for inguinal rupture is taken. This will enable the maker to estimate the vertical curve of the abdomen, which is usually marked in these cases. In children, the middle of these measurements is usually sufficient.

## CLINICAL MEMORANDA.

### TWO CASES OF SEVERE CHOREA RAPIDLY CURED BY ARSENIC.

A GIRL and a boy, afflicted with chorea to a severe degree, have been lately under my care at the Eastern Dispensary, Bath.

The girl is thirteen years old, and lives at Colerne, a village eight miles distant. She came to me first on April 19th, 1871. The action of the bowels was very sluggish, and menstruation had not appeared. I ordered a supply of medicine for ten days, consisting of some calomel and scammony powders, and three drops of the liquor arsenicalis in orange-flower water four times a day, after food. On April 29th, although the bowels had been freely moved, there was scarcely any improvement in the convulsive symptoms; and I lay emphasis on this fact, because it might otherwise be thought that the mere evacuation of the bowels was the cause of the ultimately favourable result. She was told to continue the medicines. On May 13th, the improvement was so considerable that she could walk and talk without difficulty; and on the 27th she could work well with her needle. On June 10th, she seemed quite well; but I recommended her to take two doses of the mixture daily for another month. When I last saw the girl, which was about a week ago (August 18th), the recovery was complete.

The boy is eight years old, and lives in Bath. The symptoms were not nearly so grave, but they had defied various kinds of treatment. The bowels acted in the same imperfect way; and so, when he came under my care on June 14th, I began with the same medicines, except that three drops of liquor arsenicalis were administered only three times a day. The favourable progress of the case was equally uninterrupted, and the child seemed perfectly well by the beginning of August.

In neither instance was there any history of rheumatism. In the case of the girl, there was an obscure legend that she had been "frightened" once.

It is rather remarkable that systematic writers do not lay more stress on the treatment of chorea by arsenic. My therapeutic habit in cases of chorea is always to try arsenic first. The eminent authorities of Pereira, Chambers, and Begbie, can be quoted as strongly in its favour. It is a remedy which, within specified limits, can do no possible harm; and the exceeding tolerance of children for this medicine is particularly worthy of recollection.

JOHN K. SPENDER, M.D. Lond., Bath.

FIG. 1

FIG. II

tensor vaginæ femoris and glutei muscles, which, during walking, are very apt to alter the bearing of the truss by swelling out. It does not depend upon the form of the bones or the position of the anterior superior iliac spine, so much as upon these more superficial parts. Finally, the vertical distance between the centre of the hernial aperture at *c* and a horizontal line connecting the anterior superior iliac spines should be taken at the point *b*, and carefully measured from ink-marks previously made.

There is yet another point which must be attended to if complete success is looked for. According to the degree of stoutness of the individual will be the projection of the abdomen at the hernial region, and the degree of inclination of the surface upon which the truss-pad must rest. To measure this inclination, and to guide the maker to an idea

## EXCISION OF THE SCAPULA.\*

By CHARLES STEELE, F.R.C.S.,

Surgeon to the Royal Infirmary, Bristol.

CHARLES BEES was brought to the Bristol Royal Infirmary in April last on account of a large swelling on the right scapula. The history which his mother gave was that there had been slight swelling for six weeks, but it had attracted little attention until three weeks previously, when it began to enlarge rapidly, and for a fortnight past had been accompanied by shooting pains in the part and neighbourhood. The child had also lost flesh during the last two weeks, and presented a rather delicate appearance.

The tumour occupied the whole surface of the scapula with the exception of the inferior angle, and encroached slightly over the upper border towards the clavicle, being most elevated in the situation of the spine of the scapula. In appearance it was very like a large cold abscess; and the sensation conveyed to the fingers was highly elastic in part, but in most of its surface indistinguishable from the fluctuation of pus when bound under tense tissues. He was able to move his arm freely, being embarrassed in action only in raising the limb from the side by the projection of the tumour towards the clavicle and shoulder-joint. He took food well. I watched the case for three days, and perceived very rapid increase, especially upwards towards the clavicle. I then made an exploratory opening in the centre. No pus escaped, and a probe introduced passed easily in various directions through the tumour. A particle removed and placed under the microscope showed large, almost square cells, filled with a number of smaller ones.

The next day I held a consultation with my colleagues, and we decided on excising the scapula with the tumour, leaving the question of the removal or not of the whole superior extremity until we could ascertain at the time of the operation the extent of the tumour, and what parts it involved or infiltrated. We all felt that the tumour was encephaloid; but a suggestion having been offered that deep-seated strumous abscess of bone sometimes presents a similar appearance, I commenced the operation by making a free incision in the centre of the tumour down to the bone, when the characteristic appearance of encephaloid disease presented itself, encysted in the muscles. I then made two free elliptical incisions from the upper border to the inferior angle of the scapula through the skin, embracing the previously made exploratory incision in order to avoid the possibility of infiltration. I then carefully dissected the skin off the supraspinatus and infraspinatus muscles, divided the muscles attached to the posterior border, and, having introduced my left fingers beneath the bone, slipped it from under the latissimus dorsi muscle, and, dividing the muscles attached to the anterior border, carefully released the subscapularis muscle from its cellular connection to subjacent parts, leaving it attached to the bone. We now saw that this muscle was spread over a large mass of encephaloid disease, forming a capsule to it, as did the supraspinatus and infraspinatus muscles on the dorsum. Great care was needed in the separation of the tumour along the upper border; for, though encased, it had encroached on the posterior border of the clavicle, and sent a projection under it. Evidently, in a few days more, the clavicle and its surroundings would have been involved. I disarticulated the bone from the clavicle and also from the humerus, taking care to cut the ligaments and tendons close to the latter bone, and removed the tumour entire in its muscular capsule. The suprascapular, posterior scapular, and subscapular arteries and one muscular branch were secured; the edges of the wound were brought together with horse-hair sutures and strapping; a large compress of cotton-wool was bound on, while the arm was bandaged down with the elbow separated from the side by a pad of wool, and the forearm and hand laid across the chest. Considering the amount of surface exposed, and the nature of the tumour, little blood was lost.

On examining the tumour after removal, we found it entirely encased in the supraspinatus and infraspinatus muscles posteriorly, and the subscapularis anteriorly, occupying the supraspinous and infraspinous fossae on the dorsum, rising higher over the spine. It was firm in a small portion, but softened in greater part; and at one prominent point had burst through its envelope. The disease formed on the venter of the scapula a large flat mass, of firm consistence, and projected in smaller masses above the superior border.

The patient had a dose of opium soon after the operation, and went well through the remainder of the day. Next day, his pulse was 150; temperature 101.2 in the morning, rising to 102.4 at night, at which point it remained for two days and a half; it then became variable till

the ninth day, from which day until the twentieth there was a marked evening increase, which increase diminished steadily from four degrees to one. From this date the temperature became and remained almost normal. During this time the pulse varied from 108 to 144, being greatly affected by excitement and external influences. His appetite soon returned after the operation; he did not complain of any pain, expressed himself feeling well, and improved in appearance steadily. Two days after the operation, there was promise of union in the centre of the wound, and thin pus escaped from the lower part. Next day, the pus was healthy and abundant. On the fourth day, the wound was gaping, and showed pink granulations over the surface. The head of the humerus was visible. The ligature that had been placed on the muscular branch was removed.

In the course of the next week, the other ligatures came away. The granulations became healthy, and discharged pus copiously: therefore, on the twelfth day, I had the surface dressed with chalk ointment, and ordered small doses of perchloride of iron mixture. The cavity filled up by granulation steadily; the head of the humerus, from which the cartilage gradually disappeared, was covered over; and cicatrization proceeded steadily from the edges. Action, after a short time, becoming rather languid, was restored by a more stimulating dressing of diluted red oxide of mercury ointment. Three weeks after the operation, a small abscess formed near the upper extremity of the wound, but, on being opened, gave no further trouble. The boy was soon afterwards able to sit up; then to keep up all day, move about the ward, and go into the garden daily. He gained flesh and lost his delicate appearance, his appetite meanwhile never flagging. There was every prospect of the wound being soon entirely healed, and his returning home restored to health; when, just seven clear weeks after the operation, his appetite flagged a little; his face lost its healthy look; and, two days afterwards, two small firm nodules were perceptible—one near the centre of the remaining wound, the other towards the axilla. I gave him chloroform, and excised these: the former was of the size of a marble; the latter was flattened and burrowing, of the size of a five-shilling piece. In removing this, the intercostal muscles were cleaned. These were distinct masses of encephaloid; but, though all present felt that I had removed each mass entire, and the surface left gave a natural sense to the touch, we could but anticipate, from their infiltrated character and the fact of their recurrence, that disease would again show itself. After slight feverish excitement, the patient improved again, and the wound took on healthy action; but, a fortnight afterwards, a distinct small rounded mass sprang up under the skin, a clear inch from any of the wounded part, between it and the spine. I again prepared to remove this; but, when he was brought under the influence of chloroform, on careful examination we felt the whole of the central and lower portion of the wound to be so infiltrated, giving a springy elastic feeling to the touch, and having suddenly taken on a greyish appearance, that I was compelled to retire defeated, and leave disease to carry out its ravages till its victim should be released by death.

Though this case has terminated unsuccessfully in the end, I have ventured to bring it before your notice, partly from a conviction that, in serious operations and cases, unsuccessful as well as successful cases ought to be recorded, and moreover, because this case confirms the fact that extirpation of the scapula can be in itself a safe operation; but principally to point out what this case clearly showed, even though thorough healing had not occurred, that, after removal of the entire scapula, leaving the humerus no glenoid cavity for articulation, a remarkable degree of use may be preserved in the upper extremity. From the first I supported the forearm by strips of plaster extending from the chest to the abdomen, leaving his hand free for movement, in which he indulged without pain throughout—in fact, often needing to be restrained from using it too much. I introduced a pad of cotton-wool between the elbow and side, so that, if the upper arm had become fixed, the elbow might be about three inches from the side, to allow clothes to be put on, and the forearm to enjoy free play; though at the same time I fully anticipated that tolerably free motion, certainly forwards, of the upper arm, would be preserved; for, as I said in answer to frequent inquiries on the point, I expected the head of the humerus to make a surface to work upon, and become attached to surrounding parts, as bones do in unreduced dislocations; whilst forward movement would be fully preserved, and backward could be compensated for by a figure-of-eight support from shoulder to shoulder. I encouraged gentle movements from the time when the head of the humerus was covered, and found that in about a month the forearm could be well prevented from falling; and, just before disease returned, Bees could use his forearm pretty easily, draw his arm well forwards by the pectoral muscles, keep it a little distance from his side by the anterior portion of the deltoid, and draw it backwards, not by simple gravitation after being drawn for-

\* Read in the Surgical Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

wards, but by the action of the latissimus dorsi, which, being free from disease, had slipped off the inferior angle of the scapula at the time of the operation.

It having been decided to save the upper extremity, upon finding all its muscles free from disease, it was a satisfaction to see ultimately that all the disease which occurred was in parts which would have been left even had the whole limb been sacrificed.

Observation has convinced me that encephaloid is the form of cancer most to be dreaded for returning after removal; yet, from this case in my own experience giving such great promise till, almost two months after operation, disease again showed itself, and from other recorded cases, I should not hesitate to urge, in a similar case, the same operative procedure, and to entertain hope, not only of removing disease, but of preserving a remarkable amount of use in the injured member.

[P.S. The patient died in the middle of September.]

## ON THE TREATMENT OF STONE IN THE FEMALE BLADDER.\*

By CHRISTOPHER HEATH, F.R.C.S.,

Surgeon to University College Hospital and to the Hospital for Women.

THE occurrence of stone in the female bladder is not very common, the proportion between the two sexes being, according to Mr. Poland (Holmes' *System of Surgery*, vol. iv), one in the female to twenty or twenty-three in the male. The same author remarks that "statistics respecting stone in the female, the operation and its consequences, and the mortality after operation, are incomplete and unsatisfactory." As a small contribution towards their better elucidation, I wish to record three cases of stone in the female which have been under my care, upon each of which I operated by a different method—viz., lithotripsy, vaginal lithotomy, and rapid dilatation of the urethra—all making good recoveries.

The first case occurred in 1865, and has already been published (*Lancet*, Feb. 10th, 1866). The patient was a lady aged 32, who had undergone insufficient lithotripsy two years before. The stone proved too large to extract safely through the urethra when dilated with the finger, and I therefore had recourse to lithotripsy, breaking up in five sittings a stone measuring an inch and a quarter, and consisting of phosphates with a large nucleus of oxalate of lime, which required considerable force to break it into the fragments I now show. The weight of the *débris* was 245 grains = 4 drs. 5 grs. The patient made a perfect recovery, and has remained well ever since.

The second case occurred this summer, the patient being admitted into the Hospital for Women, Soho. She was a widow, aged 49, who had long suffered from incontinence of urine. On examining her, I found a large calculus immediately within the urethra, and to be readily felt through the vaginal wall. Its size was evidently too great for it to be safely extracted *per urethram*; and the bladder was too irritable to admit of lithotripsy. I determined, therefore, to perform vaginal lithotomy, closing the opening immediately with wire sutures. This was done under chloroform on May 27th, when, the patient being in the lithotomy position, and the vagina rendered patent by means of a large Sims' speculum, I cut at once upon the stone through the anterior wall of the vagina from behind forwards, making an incision an inch and a half long, terminating behind the urethra. The stone was then readily grasped with a small pair of lithotomy-forceps, and extracted. It weighed 710 grains, or ten grains less than an ounce and a half; and measured 2 inches in length by  $1\frac{1}{4}$ , and 1 inch in thickness; and on section will be seen to consist of three angular calculi (each of which has a nucleus of urate of lime), fitted to one another in a mass of carbonate and phosphate of lime, with slender layers of uric acid. This formation is accounted for by the fact which I ascertained on passing my finger into the bladder; for there was a distinct pouch of capacity sufficient to hold the calculus, in which it had doubtless been lodged until quite recently, since the sound introduced a few days before the patient came under my care had failed to detect the stone. There was no hæmorrhage of any consequence; and I at once closed the opening with six wire sutures, passing them through the entire thickness of both vagina and bladder, and twisting them in the ordinary way. The urine was drawn off with the catheter for the first few days, and the stitches were removed at the end of a fortnight. The wound was perfectly healed at this time; but the patient had not recovered complete control over her bladder at night. This she entirely regained after using a belladonna pessary for a few nights; and, as it

was found that the uterus prolapsed on her straining, an elastic pessary was introduced into the vagina, and she was discharged on July 23rd perfectly well.

The third case was in a girl aged 11, who appears to have suffered from bladder-symptoms all her life, but who had not been sounded until she was sent to me by an old pupil in June last. I readily detected a stone, and the patient was admitted under my care into University College Hospital. On examining the stone prior to the operation, it appeared to me of a size which could be removed *per urethram* without difficulty; and this operation I proceeded to perform on June 21st. Having introduced a two-bladed dilator into the urethra, I enlarged the passage sufficiently to insinuate the little finger along a director into the bladder, and then with a pair of polypus-forceps readily grasped and removed a flat nearly circular calculus of three-quarters of an inch diameter, weighing 68 grains, and consisting of oxalate of lime, coated with phosphates. On again introducing the finger, however, I discovered that there was another larger mass of stone adherent to the upper part of the bladder, and too large to be extracted whole. Vaginal lithotomy was out of the question, on account of the small size of the parts; and I did not feel disposed to resort to the high operation, which was suggested by one of my colleagues. I therefore proceeded to break the stone down with forceps, having failed to apply a lithotrite, on account of the attachment of the stone to the mucous membrane of the bladder. By repeated efforts, and after a prolonged operation, I broke off several pieces of the stone, and at last succeeded in detaching the mass, which weighs 408 grains; this was slowly and steadily withdrawn through the urethra with a pair of small lithotomy-forceps. The nucleus of the large mass was exposed, as can be seen, and was found by Mr. Carter of University College, who kindly examined it, to be composed of oxalate of lime, the rest of the stone being carbonate and phosphate of lime. A careful washing out of the bladder brought away a quantity of *débris*, which have adhered together in drying, and weigh 80 grains, thus making the entire weight of stone removed at the operation 556 grains, or 9 drachms and 16 grains. The little patient was a good deal exhausted by the protracted operation under chloroform, and required stimulation. A linseed-meal poultice with half a drachm of laudanum on it was applied over the bladder and abdomen, and changed every four hours; and an opiate was given by the mouth. On the following day, notwithstanding assiduous poulticing, a sharp attack of peritonitis came on; but this subsided again in forty-eight hours, and from that time the patient made a good recovery. As was to be anticipated from the dilatation and laceration the urethra had undergone, the urine passed involuntarily after the operation; and, being anxious to see to what extent the laceration had gone, I put the patient under chloroform again on the tenth day after the operation. I found that the lower wall of the urethra had been torn, but was healing well; and I took the opportunity of removing from the vulva a quantity of thick vesical mucus holding calcareous matter in its meshes, which had collected about the parts; and extracted some of the same material from the bladder with forceps and a large syringe. The bladder was then washed out daily, and the patient took nitric acid with buchu. She did not recover any power over the neck of the bladder for a month after the operation, but on July 22nd was able to be up and about the ward holding the urine for an hour or more. On July 27th, she went down to Eastbourne, where she now is.

The cases narrated illustrate three different modes of treatment, respecting which I will make a few remarks. I think I may say that the old practice of slowly dilating the female urethra with sponge-tents, etc., is now entirely abandoned, since all surgeons who have had any experience on the subject agree in believing that rapid dilatation under chloroform has very great advantages over the other method. By the old method, subsequent incontinence of urine was frequently induced; whilst after the rapid dilatation such an occurrence is, I believe, unknown. I am in the habit of rapidly dilating the urethra, and of using the finger to explore the bladder, in all cases of obscure vesical disease in the female; and I have never seen any bad result follow the practice. On the contrary, I have found the method of the greatest service both in diagnosis and treatment, particularly in the case of foreign bodies. In the child whose case I have narrated, some laceration ensued, and gave rise to temporary incontinence; but this is not the case in the adult, if the dilatation be kept within proper limits. It would have, no doubt, been better, had I been able to reduce the size of the stone in the case of the girl before extracting; but in the early stage of the proceeding it was impossible to apply a lithotrite, owing to the attachment of the stone to the bladder, to say nothing of the difficulty of manipulating that instrument in the small and contracted bladder of a child. Lithotripsy in the adult female, as in my first case, is comparatively easy of performance; and the size and shortness of the urethra admit of the ready extraction of fragments which it would be very unsafe or nearly

\* Read before the Surgical Section at the Annual Meeting of the British Medical Association in Plymouth, August, 1871.

impossible to withdraw along the male urethra. With respect to vaginal lithotomy, it is, I believe, the best operation in adults with large stones. Mr. Poland (*op. cit.*) speaks of it as "a very easy and expeditious operation, but one which is followed almost necessarily by vesico-vaginal fistula and incontinence." This is not the experience of Mr. J. Lane, Mr. B. Brown, Dr. Aveling, and others who have recorded cases; and in my own case a perfect result was obtained. It is, I think, important to introduce the sutures through the entire thickness of both bladder and vagina; and, if care has been taken to make a sufficiently large opening into the bladder, so that the edges of the wound may not be bruised in extracting the stone, complete union readily takes place. I have known an unsuccessful result caused by the operator occluding the urethra with one of the sutures; and I have also known death follow a very prolonged operation for the removal of a very large calculus through an utterly inadequate opening; but these results do not detract from the merit of the operation when properly and carefully performed.

*Postscript.*—On the return of the last patient from Eastbourne, it was found that she still had incontinence, and, on examination, the anterior part of the urethra was seen to be torn. To remedy this, the galvanic cautery was applied on three occasions with benefit, and without any interference with the patient's health. During the last week of September, however, she began to complain of great pain about the left kidney, and gradually sank, dying on October 1st.

At the *post mortem* examination, an abscess was found in the upper part of the left kidney, which had burst. The pelvis of the kidney contained a quantity of grumous pus and particles of phosphatic matter, and the lining membrane of the pelvis and ureter was thickened and injected. On cutting into the right kidney, its pelvis was dilated and filled with pus around a large branched phosphatic calculus fitting into the infundibula; its ureter was also much thickened; the bladder was healthy and contracted. The urethra was of little more than ordinary size, and showed a slight rent in the floor at the orifice. The other organs were healthy.

## NOTES OF SEVEN CASES OF POISONING BY SEWAGE-WATER.

By CHARLES J. GIBB, M.D.,

Consulting Surgeon to the Newcastle-upon-Tyne Infirmary.

On the 8th of August, the weather having been exceedingly hot for some days, I was requested to visit an establishment where several of the servants had been taken suddenly ill. I found that four female servants had become ill during the night, and were in bed; two more became affected on the following day, and a male servant had been compelled to go to bed ill of the same complaint. Six out of the eight female servants of the house were affected, and one of the four male servants.

The symptoms in all were very much alike, but a young female servant presented the worst features. She had felt some slight weariness and nausea the day before, but did not consider herself ill until during the night, when she was seized with severe vomiting, profuse dark bilious diarrhoea, and severe colic-like pains in the abdomen, followed, after a few hours, by intense tenderness at the epigastrium on pressure, and great flatulent distension of the whole abdomen. She had a red, dry, and very hot skin; rapid and bounding, but soft pulse; and a large moist tongue, coated with a fur as if yellow clay had been thickly painted over it. She had, also, some slight cramps in her legs, and that headache, back-ache, limb-ache, and general weakness, weariness, and incessant tossing about, which accompany acute febrile attacks of stomach and intestinal disorder. She constantly exclaimed she was going to die, so sinking and ill were the feelings she experienced.

These violent symptoms continued for thirty-six hours. Slight delirium set in during the second night. All the symptoms abated considerably during the morning of the second day, more as if nature had become exhausted, than as if the disease were in process of resolution; for on the third day, a fresh accession of violent vomiting and purging, with pain and distension of abdomen, and high fever recurred, lasting, however, only about twelve hours. After this relapse, all the symptoms gradually lessened in severity, slight vomiting and purging continuing for two more days. By the end of the week, she was able to digest broths and farinaceous liquids, and, although unable to sit out of bed, was carried to her own home, where she quickly recovered her strength. There appeared to be a feeling of such intense nausea all through the attack, that, even when her skin was burning hot, she did not manifest that eager desire to drink cold or iced liquid, which is so marked a symptom of regular fevers.

The symptoms of two of the other female servants nearly approached this one in severity; a fourth one had the vomiting, diarrhoea, colicky pain, and nausea in a minor degree, with only very slight fever and constitutional depression, whilst the sixth continued at work, and only felt slight weariness, nausea, diarrhoea, and loss of appetite for a few days.

On my first visit, I was convinced that all of them were suffering from one common cause of disease, most probably from some irritant food, or the effluvia of some deranged drain; but although I traversed the house, questioned the cook, and examined all the drains and water-closets, I failed to discover any cause to account for the outbreak. They all complained of having been completely worn out by very hard work during the preceding week of intensely hot weather, and of being dripping with perspiration all day long; and to this they attributed their illness. Two days afterwards, however, I discovered they had been compelled to send to a neighbouring pump for drinking-water during the hot weather, the ordinary drinking-water from the cistern of the house having become so foul, even to the smell, that they were compelled to cease using it. They had, however, according to their own account, drunk it very largely even in that condition. I at once concluded that the source of the disease lay in the cistern; and on questioning the heads of the house, found that they did not know where the cistern was placed, and that it had certainly not been cleaned out for a long time. I at once sent a note to the Secretary of the Water Company, and he kindly investigated the water-supply of the house.

The cistern supplying the drinking-water was found under the floor of an upper water-closet, with overflow-pipes so placed that, when a negligent servant threw the contents of her slop-pail into the water-closet, and made it to overflow, the overflow found its way into the cistern of drinking-water. The following is an extract from the letter I received from Mr. Secretary Main, after he had completed his survey.

"It was difficult to say how much dirt was in this cistern when I examined it this morning, as the man no sooner got into it than the whole became black and greasy-looking. The water standing in a cistern only ten inches deep, and in a filthy condition, must soon putrefy. The arrangement of passing the water through such a cistern before being used, is bad; it is so small that it is of no use as a store, and it must at all times, I should think, exposed as it is to the dust and atmosphere of the water-closet, have a tendency to render the water impure. I should recommend that a cistern much deeper should be put up in a better position, or that the taps for cooking and drinking-water be entirely disconnected from the present cistern, and the supply taken direct from the main-pipes."

There can, I think, be no doubt that putrid water was the immediate cause of the illness, and that the symptoms arose from sewage-poisoning, intensified by the exhaustion of hard work, and the predisposition to such complaints which existed during the exceptionally hot weather prevailing at the time. The symptoms approached in severity those of an irritant poison. The septic influence of the putrefying agent was apparent in the intense nausea and depression. The symptoms resembled in some points a very acute or explosive attack of enteric or typhoid fever; yet the absence of all eruption, and the comparatively short duration of the attacks, made it impossible to classify it as a specific or sporadic fever.

## EXFOLIATION OF THE BLADDER.

By WALTER WHITEHEAD, F.R.C.S. EDIN.,

Surgeon to St. Mary's Hospital for Diseases of Women and Children, Manchester.

THE exfoliation of casts and shreds of membrane from the bladder, though rare, is still of more frequent occurrence than some of those who have recently recorded instances in the JOURNAL would appear to admit. Mr. Clement Godson, for instance, read at the Medical Society of London, on January 3rd, 1870, the case of a patient who had been under his care when resident obstetric assistant at St. Bartholomew's Hospital. Mr. Godson was good enough at the time to supply me with further details, in consequence of his knowing that I was interested in the subject; and I am sure he will pardon my publishing the following abstract from his notes, as every ray of light must tend to explain the cause of this singular phenomenon.

"M. D., aged 26, had been married six years, and had had four children. She was admitted into St. Bartholomew's Hospital on November 27th, 1869, under the care of Dr. Greenhalgh. She was pale and poorly nourished. She stated that she had lost much flesh lately; that she was advanced three and a half months in pregnancy, her last period having terminated early in August; and that on November 16th, in the morning, on getting out of bed, she found herself unable to

pass her urine. Her medical attendant passed a catheter, and relieved her of a pint, and told her that her womb was misplaced. Since this time, her urine had been dribbling away, and she had been suffering great pain in the lower part of the abdomen, so much so, that the surgeon in attendance had made three ineffectual attempts to replace the womb. On admission, the patient was very pallid; the lips were covered with sordes; the pulse was small, quick, and compressible. The abdomen up to the umbilicus was very tender on pressure. The vagina was very short, hot, and tender. The cervix uteri was close against the pubes; and posteriorly there was a soft well defined elastic swelling reaching below the level of the cervix, and with a distinct sulcus between them. The rectum was almost occluded by the swelling. A catheter having been passed, ninety-six ounces of urine, containing some blood, were withdrawn; and again at night forty-eight ounces. On November 28th, at 8 A.M., seventy-two ounces of urine were drawn off, containing less blood; and at 9 P.M. forty-three ounces were withdrawn. The urine was drawn off for several days. On December 10th, she passed it herself; it was thick, ropy, and offensive. On the 21st, the urine was very dark, more ropy, but not so offensive. On the 23rd, the body of the uterus had risen almost completely from its previous position. On the 24th, the urine was alkaline, scarcely at all offensive. On the 26th, urine dribbled away; it could not be retained. On the 27th, at 1 A.M., the patient felt a desire to pass urine, but failed. Mr. Godson, the resident obstetric assistant, found a white substance protruding from the urethra, and removed it by gentle traction. It presented the appearance of a large bag, exactly resembling mucous membrane, and was followed by a small quantity of highly offensive urine. At 11 A.M., the patient had slept fairly, but had been continually grinding her teeth. Pulse 112, small, regular; temperature 98 deg.; skin moist. She had passed some urine, less alkaline, and with less pain. The bladder was ordered to be washed out with tepid water. On January 3rd, 1871, the patient slept well, and suffered no pain. The urine was faintly alkaline, clear, containing very little mucus. On the 6th, the patient said that for the last two days she had been unable to retain her urine for more than ten minutes. The urine was clear, but slightly alkaline. The bladder had not been washed out since the 4th: the washing was ordered to be repeated. On the 10th, she could retain her urine for fifteen minutes. The bladder was ordered to be washed out every other day. On January 19th, the urine was slightly alkaline. The patient could not retain it more than fifteen minutes. She suffered no pain, and was very well, with the exception of this inconvenience."

This pathological specimen, Mr. Godson informed me, was a perfect bag, and sufficiently large to contain within it a closed fist. This is much smaller than those usually voided when in a complete state. This specimen is, I believe, now in the museum of St. Bartholomew's Hospital.

In January 1866, I attended the wife of a shopkeeper in her first confinement. For some months previously, she had suffered from repeated attacks of retention of urine; and during the last week or ten days the retention was prolonged until catheterism was necessary for her relief. Some hours before delivery, and just as the head was passing the brim, I became aware that something unusual was present at the vulva; and, prompted by curiosity, I witnessed a perfect cast of the bladder pass *per urethram*.

I have also known of several cases where the mucous membrane has sloughed away from the bladder, and where there has been a previous history of attacks of retention of urine in the first instance, followed by an abnormal urine, the result of such retention; and, finally, exfoliation and expulsion *en masse*, or in shreds, of the mucous lining of the bladder. In some instances, pyemic symptoms and death have been reported to have rapidly ensued.

The constitutional disturbance noted throughout the progress of these cases, except during the periods of retention, is singularly out of proportion to the seriousness of the lesion and the delicacy of the viscous implicated. It would appear to occur most frequently to women, and, in every instance with which I am acquainted, after some interference with the emptying of the bladder—to be, in fact, one of the usual causes of retention of urine.

In Mr. Godson's case, a retroflected pregnant uterus was apparently the impediment; in the case which I have just mentioned, an unusually large gravid uterus. Consequently, the suggestion of Dr. J. J. Phillips, in the BRITISH MEDICAL JOURNAL for June 24th, 1871, page 662, that retroversion of the gravid uterus may be one of the causes of exfoliation of the lining of the bladder, receives confirmation and support.

The casts cannot strictly be looked upon as simply an exfoliation of the mucous membrane of the bladder, as they do not consist entirely of mucous membrane. Muscular fibre, and even serous tissue, are often,

if not generally, attached to and incorporated with the mucous lining; and, further, we have the distinct fibrinous casts.

It is very much to be desired that, whilst this subject is being made prominent, those who have met with such specimens should add their quota to the common stock of experience, in order that some more definite conclusions may be arrived at concerning the cause, course, and treatment of such remarkable cases.

## ON THE CLIMATE OF SYDNEY AND NEW SOUTH WALES.

By JOHN C. THOROWGOOD, M.D.

AT the present time, when opinions seem to vary as to the beneficial effects of the Australian climate in cases of pulmonary disease, the following observations and personal experience, furnished to me in a letter from my friend and former patient, Dr. Lightbody, may interest some of the readers of the BRITISH MEDICAL JOURNAL.

The writer tried a winter in Madeira and lost ground there, neither did he find any improvement on his return to England for the summer. Pains, dyspnoea, and moist sounds in one lung, still remained as the troublesome symptoms, and in 1870 he arrived in Sydney. There, by a judicious use of the advantages of elevation offered by the surrounding district, he appears completely to have regained health and vigour, and all the worst symptoms have passed quite away.

The summer at Sydney is relaxing, and a change inland to the region beyond the Blue Mountains at an elevation of 2150 feet may be made with speedy advantage to the patient. A glance at the following statement will give an idea of the range of temperature in Sydney, and of the death-rate there.

Mean temperature of Sydney for 10 years, 62 deg. 6 sec.; January (hottest month), 70 deg. 9 sec.; July (coldest month), 52 deg. 2 sec. The total deaths in New South Wales, out of a population of 475,574, were, for the year 1869, 6691; being a ratio of 14.06 per 1000. Taking the city, suburbs and country separately, the ratio per 1000 for 1869 was: city of Sydney, 20.33; suburbs of Sydney, 18.11; country, 12.14. Of the 6691 deaths, miasmatic disease caused 1366, or 20.41 per cent.; nervous diseases, 943, or 14.09 per cent.; tubercular diseases, including scrofula, phthisis, hydrocephalus, 504, or 7.53 per cent.; accidents, 513, or 7.67 per cent.; diseases of nutrition, 477, or 7.13 per cent.; diseases of digestive organs, 457, or 6.83 per cent.; diseases of circulatory organs, 345, or 5.16 per cent.

The extreme range of temperature at Sydney is from 32 deg. to 105 deg., and both these extremes occur with the dry west wind; but, as bananas and some kinds of apples and pears ripen their fruit well, the extremes of temperature do not seem to have the same effect as they would have in England.

Among the lower class of the population phthisis appears less common than it is in the corresponding class in Scotland, and that too in spite of a greater amount of intemperance and syphilis. Among the better classes phthisis is often met with, chiefly, however, in the persons of those who have come out to Sydney for their health; many of these completely recover, marry and have families, and it is singular how healthy these families are in many instances. Two families Dr. Lightbody selects as examples in illustration. In both of these the fathers came out for their health thirty years ago, one being slightly diseased in the lungs, the other seriously so. In the one family there are now seven children, in the other five; the eldest of the children is 28 years of age, the youngest 14. In neither family has there been a death from phthisis; and only the eldest child in each family has shown any sign of the disease, and these are now in fair health.

The climatic advantages of Sydney seem great. If in the summer it be too hot and relaxing, six hours by rail will carry a patient to an elevation of 3500 feet, where he will find a dry bracing air and cool nights, while a further journey of three or four days will land one on the great plains where a climate not unlike that of Egypt, only drier, is to be found.

Of the climates of which Dr. Lightbody has made personal experience, he describes that of Mentone as being most like the Sydney climate; but at times during the summer at Sydney, when the moist relaxing north-east wind blows, which it does but for a few days only at a time, then the climate seems to have been suggestive of Madeira.

The winters at Sydney are bright and sunny, the wind generally westerly and the nights cold. Epidemic disease seems rare, though measles at times proves very fatal among children. During the last six years the average death-rate has been 17.22 per 1000.

The voyage out to Australia seems, in the words of Dr. Lightbody,

to have been a "powerful agent for good" to three invalids who were in rather advanced stages of phthisis. One lady with a cavity in the lung did not improve at all till the ship entered the tropics; she then steadily mended, and when last heard of was living on the borders of Queensland in excellent health.

I am here reminded of the case of a young chemist seen by me and also by Dr. Walshe in the spring of 1869. Unmistakeable phthisis was established and making progress in the left lung; he went to Brisbane, and then further up the country, and the last account that he sent home was, that he was so stout and robust that we should hardly recognise him again.

It seems as if, while emigration is the remedy for a surplus population, it will also powerfully act if judiciously used as a means of correcting hereditary tendency to disease, and so improving the breed of mankind.

## CASE OF HYDROPHOBIA FOLLOWING THE BITE OF A CAT.

By G. M. BRUMWELL, M.D., Mossley, Manchester.

THE following are the particulars of a case of hydrophobia which has occurred in my practice.

Rev. D. Berry, aged 32, Unitarian minister, Mossley, was bitten by his cat on May 14th, 1871. The cat, which was a great pet, had been observed to be "ill" for a week or so. Its habits were not so clean as usual; it seemed to wish to keep out of the way of the children, retiring under the sofa, etc.; and was irritated when accidentally touched on passing. There were some loss of power in the hinder extremities, and frequent micturition.

On May 14th, the little boy, aged two years and a half, crept under the sofa to play with the cat, when it either scratched or bit him in the hand. Mr. Berry, on seeing the boy's hand bleeding, laid hold of the cat to beat it, when it bit him rather severely in the left thumb, and more slightly on the back of the right hand. The thumb bled profusely. Mr. Berry sucked the wounds, put both hands into salt and water, and then immediately came to my surgery, which is only a few yards distant; and my assistant freely cauterised the wounds with nitrate of silver, and ordered him to poultice them for a week. The wounds healed quickly. I was from home at the time, and my assistant did not report the case to me. The cat was shot the day following by a man who has had great experience in the training of sporting dogs; and he affirms that the animal was foaming at the mouth, and had all the appearance of being mad.

On August 10th, Mr. Berry was from home, and felt pain and numbness in the left hand and arm, and was sick and faint. On the 12th, he returned home to attend a funeral. I saw him at 1 P.M. He complained of being "very ill." He was sick, he said, which he attributed to having eaten pork two days before. I then, for the first time, heard of his having been bitten by his cat. He said he had lately felt pain in the left arm, and tingling in the fingers of both hands. He told me he awoke the night before he came home with a sense of suffocation. In the morning, on dipping his face into the water, his usual custom when washing, it made him "gasp for breath." At breakfast, he had great difficulty in swallowing a cup of tea. When I saw him, his countenance was expressive of great anxiety; and, on his attempting to drink a glass of water, he had immediate spasm, which produced a choking sensation not soon overcome. I advised him to go to bed, telling him his nervous system was thoroughly out of order, and that he needed rest and quiet. His tongue was very foul, and the bowels costive. I gave him an emetic of ipecacuanha, and afterwards a purge. Dr. Shepherd Fletcher, of Manchester, saw him with me the same evening, and concurred in my suspicion that the case was one of hydrophobia. We agreed that the first indication was to tranquillise the patient's mind, and to procure sleep. The patient, in describing the sense of suffocation, referred to the margin of the ribs, and said "it came like a wave through the bowels up into the lung." He also constantly referred to a sensation in the throat which affected his breathing; this latter symptom was persistent throughout, always greatly aggravated on attempting to swallow fluids, which were gulped down with a very great effort, the patient being a man of strong and determined will.

A subcutaneous injection of morphia procured for him a little sleep; and, on the following morning (13th), he felt better, but the aversion to fluids was the same. During the day, he took ten-grain doses of bromide of potassium every three hours. He also took beef-tea twice, and a little bread and jam with a cup of tea. Warm fluids did not produce the same effects as cold water. He complained that his throat was "inflamed," and of his own accord applied a "wet pack." In

the evening, he slept an hour, and awoke at 9.30 much excited, and drenched in perspiration, saturating the bed on which he lay. I was hastily summoned. He was constantly wiping the saliva from his mouth; he talked incessantly; said he was dying; gave the most minute orders as to his funeral, etc. He asked for a sponge soaked in water, to apply to his mouth; he said, "I cannot bear the thought or sight of water, it must be banished from my table for ever; I cannot bear to hear the water running from the tap." I tried to quiet his mind. I gave him half a grain of morphia in pill, and, in about an hour, injected hypodermically another grain. At the same time, I also gave him a drachm of chloral hydrate in treacle, on the suggestion of my neighbour, Dr. J. L. Andrew, who saw the patient with me. These remedies failed to procure sleep; he talked the whole night, and told me, early the following morning, he wished what he had said could have been written down, as he was sure he had been inspired. I gave him, at 6 A.M., another drachm of chloral. He complained of pain in the left arm, just above the elbow, and said he felt weak; there was the same restless anxiety, the constant apprehension of impending death, and the sense of suffocation in the throat. At 3 P.M., Dr. Fletcher again saw him, and suggested extract of Calabar bean, in grain doses, every hour, and as much nutriment as possible. The patient continued to take beef-tea, and, in the evening, ate a mutton chop with a cup of tea, and thought himself much better. Frequent spasms of the muscles of respiration occurred. At 9 P.M., I gave him another drachm of chloral. No relief being obtained, at 11 P.M., I repeated the dose of chloral. After 12 P.M., he slumbered for about two hours, and then the same restlessness returned. I saw him a little after six in the morning; his manner was sullen and irritable; there was also some incoherence; any movement of the bedclothes produced a painful sense of choking and suffocation; he was much weaker, and appeared to be rapidly sinking. At 11 A.M., I again saw him; his condition was most distressing; his appearance was wild, tossing about from side to side almost exhausted; he was spitting his saliva all over the carpet, and seemed to have the greatest difficulty in getting it out of his mouth. He seemed to realise the nature of his malady for the first time, and said to me, "this is the end of the cat; I know that I shall have to be smothered." I assured him that such was never the case. He soon afterwards became utterly exhausted, and died at 3.50 P.M., on the fourth day of the attack, and three months from the date of the bite. The pulse was never very quick, excepting during the periods of excitement and spasm.

I may add that a dog in a rabid state passed through the neighbourhood two or three weeks before the cat bit Mr. Berry.

## HECTIC FEVER IN PHTHISIS PULMONALIS.\*

By ROBERT W. FOSS, M.D.

HECTIC fever, or, as some prefer to call it, the hectic state (or condition), is so called on account of its chronicity and intractableness. The word is derived from the Greek adjective *ἥκτικός*, signifying habitual. It is a state common to many diseases of long duration, attended with suppuration, although not necessarily so. It is a fever of a remittent type, in which the bodily functions suffer most; the mental powers being little or not at all affected till the approach of death. It is defined by Christison thus: "A form of remittent fever of long and indefinite duration, consisting of an exacerbation once or sometimes twice a day, attended with extreme attenuation of the body, and depending either on suppuration or upon important organic derangements of structure." In phthisis there are generally indications of its approach before it completely sets in, such as slight rigors, followed by profuse perspirations; but the real symptoms, when they make their appearance, are easily distinguishable from any other similar affection by their almost regular periodicity and succession. What I wish to show is, that it is by this regularity and periodicity that the symptoms are so strikingly characteristic; and, as an example, I will give some short notes of a case.

C. D., aged 20, female. Her father and mother died of phthisis. She herself was healthy till two years ago, when she had "inflammation of the lungs". After this she had a constant cough. She often had slight attacks of hæmoptysis. About five months before the date of this report, she expectorated a teaspoonful of blood. She had had night-sweats from the beginning of her illness. The ends of her fingers were clubbed. The catamenia had been absent six months. The cough was accompanied with yellow nummular expectoration. There was dyspnoea. The tongue was red and irritable-looking. The appetite was bad. The bowels were regular. The pulse was 108. The decubitus was on the right or least affected side. On the right side, percussion was dull.

\* Read at the annual meeting of the Northern Branch.

The breathing at the apex was bronchial, and lower down harsh. On the left side, at the apex, there was bronchial breathing, which below the third rib became amphoric. There was cavernous percussion. Posteriorly, she had bronchial amphoric respiration.

About an hour after waking she had rigors, which recurred all the morning, causing aching pains in her limbs, with headache. Each rigor lasted about half-an-hour; then there was an intermission of two or three minutes, immediately followed by another rigor. About 1 P.M. she had a feeling of burning heat in her forehead, hands, and feet, and her face was flushed, more especially the left side, proving in this case, as some consider it to be, that in hectic the greatest flush on the cheek corresponds to the most affected side of the chest. During the rigors the finger-nails turned quite blue. About 4 P.M. she began to return to her natural condition, and remained so till next morning. She had suffered thus for three months. This patient died shortly after these notes were taken.

After the hectic is fairly established, it shows itself at variable times, from a few minutes to an hour after waking. The patient feels cold and has a rigor; his hands and feet become of a livid colour—more especially the finger-ends—also the nose and more prominent parts of the face; he feels very cold and gets close to the fire, with very little relief to his sufferings. He remains thus, having rigors at variable intervals, till noon, when he begins to feel warm again, until this state gives place to a feeling of intense heat; the hands and feet burn; the face is flushed as often generally as in circumscribed patches; often one side is more flushed than the other, and that corresponds to the side of the chest which is most affected. During this period there is complete prostration of strength, accompanied by burning headache, and very often the patient perspires much. This period usually continues till about 5 P.M., when the patient gradually returns to his normal state of health, and remains so till next morning. There may subsequently be an attack of rigors of short duration, followed by the usual phenomena of the hot stage; but this second attack rarely lasts more than half-an-hour altogether. The morning stage of cold lasts, on an average, three hours, and the hot stage about the same time—a little less, perhaps—the patient being at other times as in health.

The temperature in the axilla during the cold stage is about 98 deg. Fahr.; and when the hot stage sets in it rapidly rises, until it often reaches 103 deg. at its height. In Wunderlich's work on *Medical Thermometry*, recently published by the New Sydenham Society, the following occurs. "Their course is sometimes very irregular, yet they generally approach some definite type, which, although perhaps exchanged for another in the course of the disease, is still marked for a considerable space of time with considerable regularity. Their type is usually remittent, with one or two exacerbations in the course of every day. These exacerbations are sometimes slight, but sometimes severe, or extremely so, so that the temperatures daily or twice daily reach a similar elevation, and in the remission fall again to normal or even below it; sometimes there is what I may call a tertian rhythm, or, in other words, there may be intervals of a day between the exacerbations, or the rhythm may be still more extended. When death approaches, or when complications occur, the remitting type often changes into a continuous one." The pulse itself undergoes as great variations, being generally under 90 during the cold stage, and often rising to 120 during the hot stage. In character it is small, irritable, and compressible. The hectic paroxysm terminates by perspiration in about one-tenth of the cases, according to Louis; and I think that profuse perspiration is now more regarded as one of the earlier signs of phthisis rather than a late one, which opinion I find to be stated in a translation of Paulus Ægineta, somewhat obscurely, perhaps, thus: "While, therefore, any of the natural moisture remains, the fever is only hectic; but where the humidity runs the risk of being altogether consumed, a true marasmus is formed," which also includes the fact that often shortly before death, in phthisical patients, the hectic disappears. From the frequent mention of the word hectic in old authors, this condition seems to have been closely studied in ancient times. The pathology of this state must be looked for in the sympathetic system. There is no doubt now as to the regulative power exercised over the capillary vessels by this system; and as we have, at one period of the day, in this condition a deficiency of blood in the superficial capillaries—as indicated by the symptoms—and at another an excess of blood, the regulative power must be at fault somewhere, whatever the great sympathetic centres in the chest may have to do with it.

Most authors in describing this fever forget to mention the cold stage; only describing a hot stage, beginning in the evening, attaining its maximum intensity at midnight, and then undergoing a gradual lysis, chiefly by profuse perspiration; this perspiration being sometimes replaced by diarrhoea, which is then said to be colliquative. Colliquative diarrhoea is denied by most authorities now; and, so far

as I have been able to observe, it does not exist, in the sense that, if the hectic paroxysm do not terminate by perspiration, it certainly will by diarrhoea. If such ever were the case, it must be accounted for by reason of ulceration of the bowels being usually present when hectic has made its appearance. Treatment is of little avail in this condition; the disease goes on from bad to worse, the patient usually succumbing from its effects; the preparations of cinchona and dilute sulphuric acid being most frequently prescribed for it—the former from their well known anti-periodic effects, the latter chiefly from its refrigerant qualities; but neither of them ever appeared to me to relieve the patient's sufferings, so that when the disease has reached this stage all that can be done is to treat the various symptoms as they arise, and in that way endeavour to obtain for the patient an euthanasia.

## SOME OF THE ILL EFFECTS OF BROMIDE OF POTASSIUM.

By T. O. WOOD, L.R.C.P.,

Medical Superintendent of Dunston Lodge Asylum, and Lecturer on Psychological Medicine in the University of Durham.

HAVING been in the habit of using this drug somewhat extensively in my treatment of the insane, I venture to add my testimony to that of other correspondents of the JOURNAL as to its probable ill effects.

When given continuously and in large doses, it produces a great variety of results, depending generally upon the constitution and bodily condition of the patient at the time of its administration. Its most dangerous effect is when, after a course of comparatively small doses which do not seem to be taking any great hold upon the system generally, or upon the mental symptoms to control which it is given, it suddenly, and without apparent cause or warning, displays its cumulative effect, and rapidly reduces the patient to a condition of great bodily prostration, and completely alters the character of the mental symptoms. This physical prostration is at once evident. There are great muscular debility; dimness of sight, with dilated pupils; irregular gait, the patient reeling as though intoxicated; whilst nausea, vomiting, or purgation, with abdominal pain of a dull aching character, may also be present; the breath having a disagreeable odour, which seems peculiar to those who have been for any length of time under the influence of the bromide. Its effect upon the mental symptoms is no less marked. The patient who has been violently excited, glorying in his imaginary power of body and mind, becomes desponding, sullen, melancholic, and frequently lachrymose, often even despairing. One patient, who was discharged from this asylum "recovered", has since told me that he knew and felt for some time afterwards the effect of the medicine upon his mind. It produced a feeling of despondency which at times quite overcame him. These ill effects the two following cases may somewhat illustrate.

CASE I.—M. T., a strongly built man, aged 35, the subject of acute mania, in good bodily condition, dangerously excitable, and violent, was given bromide of potassium in increasing doses up to a drachm three times a day. This was continued for about a week, producing no apparent effect either upon body or mind, when one morning his symptoms presented a most marked and alarming change. He was unusually quiet, sitting languidly on his chair. He could not collect his thoughts to answer a single question properly. The extremities were cold; the heart's action was very feeble. He was given at once a glass of spirit and hot water, put to bed, and kept as warm as possible. The spirit was repeated every four hours, and he had half a drachm of aromatic spirit of ammonia an hour after each dose of the brandy. The brandy and ammonia soon had the effect of restoring the circulation and warding off the threatened syncope, though several days elapsed before he was himself again.

CASE II.—A. B., a tall well built man, aged 55, suffering from "general paralysis of the insane", was given the bromide in doses of half a drachm three times a day to allay great excitement. This, in a fortnight producing little effect, was gradually increased to a drachm thrice daily. After taking these doses for a few days without much apparent effect, he seemed all at once to give way. In the morning, he was dull, depressed, irregular in his gait; in the afternoon, he seemed to be completely helpless. The heart's action was feeble and intermitting; the extremities were cold. He was sick and giddy; could scarcely stand, and that only with support. At times he cried most bitterly; yet twelve hours previously he was singing and dancing, saying he was "the happiest man alive". Such is a brief outline of the cumulative effects of the bromide when given alone. *Experientia docet.*

Having read Dr. Clouston's admirable paper on the combination of

tincture of cannabis Indica with the bromide, I resolved to give it a trial; for, as he says, "cannabis Indica being a diuretic, and the bromide of potassium being carried off by the kidneys, it is probable that the former in that way helps to prevent the cumulative action of the latter when given alone."

CASE III.—M. T. (the subject of Case 1) was readmitted eighteen months after his discharge, presenting all the symptoms of excitement and violence as on his previous admission. I immediately gave him half-drachm doses of the tincture of cannabis Indica and the bromide, increasing this in a week up to a drachm of each three times a day. This treatment was continued for a month, and produced considerable calmarative action; though, on account of the severe dyspeptic symptoms which it produced, I deemed it advisable to discontinue it. Thus the combination in this instance had the effect of preventing any cumulative effect; and no doubt, had the continuance of the medicine not been contraindicated by the gastric disturbance, the result as to the mental symptoms would have proved even more satisfactory.

CASE IV.—B. W. W., admitted at the same time as Case III, a tall, well made, strong, and physically healthy young man, aged 27, was placed under the same treatment at the same time as Case III. He, however, not displaying the dyspeptic symptoms that Case III exhibited, the bromide was pushed to a drachm and a half with the same quantity of tincture of cannabis Indica, and eventually up to two drachms of each drug thrice daily, with the effect of producing "a state of drowsy calmness of the nervous system", and without in this instance producing any symptoms of dyspepsia, of physical exhaustion, or of threatened syncope; and thus, as far as these cases go, proving the utility of the combination.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

#### MIDDLESEX HOSPITAL.

CASE OF KIDNEY-DISEASE: SYPHILIS: GONORRHOEAL BUBO OR PYÆMIA.

(Under the care of Dr. HENRY THOMPSON.)

JOSEPH POTTER, a cabinet-maker, aged 26, was admitted on July 4th, 1871. There is no history of phthisis in the family, and his brothers and sisters are in good health. The patient himself led a very intemperate life two years ago; but, according to his own account, never suffered a single day's illness until eighteen months ago, when he had chancres, without, however, any secondary symptoms ensuing. About six months ago, he again contracted a chancre, which healed without medicine, but left him liable to sore throat ever afterwards. Six weeks ago, he had gonorrhoea, followed by suppurating bubo in the left groin.

On July 1st he was seized with repeated rigors, succeeded by great heat and vomiting, but no sweating and no pain in the back or limbs. The next day he had rigors in the afternoon, and vomiting, with severe diarrhoea and acute pain in the abdomen. On July 3rd, there were no rigors, but the pain in the belly, the vomiting, and the diarrhoea continued.

On admission, July 4th, the pulse was 116, respiration 28, temperature 100 deg. The face was pale and of a dirty yellow tint. The whole mucous membrane of the mouth and fauces was injected; that covering the hard and soft palate was dry and of vivid red colour. The velum was thin and wasted; there was an ulcer on the right tonsil, and considerable tenderness was present over the whole abdomen. He had no cough, but frequent hawking of a viscid phlegm. Respiration was purely thoracic; the abdomen was absolutely still during the process. —9 P.M. His urine was of specific gravity 1.014; it contained a fifth part of its volume of albumen; pulse 114, respiration 32, temperature 102 deg. He had constant vomiting and profuse perspiration.

July 5th.—He had no vomiting since 5 A.M. The bowels were twice open; the motions were of natural consistence, but light coloured and very offensive. There was great distension of the abdominal walls, which were rigid, but moved slightly with respiration. There were a few spots of psoriasis on the outer aspect of the elbows; and traces of a rash in front of the right elbow-joint, and a few papules on the palmar surface of the hands. Under the microscope, the urine presented a multitude of casts, chiefly epithelial, some coarsely granular, others massive and hyaline; along with scattered blood-corpuscles and free renal epithelium, containing many fat-globules and much granular material. The amount passed in twenty-four hours was about ten

ounces.—9 P.M. Pulse 142, soft and weak. Respiration 36, short and gasping. He complained of want of air. The hands were clammy. The pain had abated.

July 6th.—Pulse 138; respiration 36; temperature 100. He had an attack of epistaxis this morning. His throat was very painful; he could scarcely swallow at all. There were two or three small ulcers above the uvula. The mucous membrane of the palate was deeply injected, and the pharynx was covered with clots of blood. He had no sleep during the night beyond a few minutes at a time. The urine was of specific gravity 1.020; it contained one-third of albumen. Six ounces were removed by catheter, and two ounces passed naturally afterwards. —9 P.M. Pulse 150, respiration 32, temperature 101 deg. The skin was moist and clammy. He had slight delirium and bewilderment.

July 7th.—He died at 5 A.M.

Necropsy, July 8th.—The body was somewhat emaciated. There was a large scar in the left groin, partially healed. The larynx was intensely injected, but not ulcerated. Both lungs were congested; the bronchial membrane was deeply engorged. The right lung was adherent at the apex, where there was an old cicatrix, with increased fibrous tissue, surrounding a cheesy deposit of the size of a small hazel-nut. All the cavities of the heart were full of decolorised clot. The pericardium contained an ounce and a half of turbid serum. The intestines were all matted together with recent lymph and pus; and the peritoneal sac contained a large quantity of purulent fluid. The sigmoid flexure immediately beneath the scar in the groin was firmly adherent to the psoas muscle, but there were no infiltrations of pus either within the substance or upon the surface of that muscle, or the iliacus. The liver was large, fatty, and smeared with recent lymph. The kidneys were deeply congested, enlarged, and fatty. Many of the inguinal glands were still suppurating. There was a considerable quantity of pus in the right knee-joint.

REMARKS.—The above case presented a good problem in diagnosis. Clearly, at a glance, it was a case of peritonitis, but the nature and origin of the peritonitis were not so clear. The history and symptoms strongly betokened pyæmia; accordingly, at the first visit, the peritonitis was set down as probably pyæmic, and the pyæmia itself ascribed to the suppurating bubo. Subsequently, an examination of the urine gave indisputable evidence of advanced kidney-disease. Here, then, were two possible origins for the peritonitis. On the principle of economy in causation, it was thought proper to discard the one and to accept the other; and the choice naturally fell on the kidney-disease, which was known to exist, although some misgivings were felt about the diagnosis until the very last. The necropsy placed beyond question the existence of pyæmia, plainly due to the bubo, in the absence of all other direct sources of blood-contamination; thus proving the first hypothesis to have been right, and the second to have been wrong; not that the one was entirely wrong, or the other entirely right, inasmuch as there are strong grounds for believing that, without the co-operation of the kidney, the bubo alone would have failed to produce pyæmia. Syphilis can hardly be supposed to have influenced the result either directly or indirectly; the bubo originated in gonorrhoea, and the kidney-disease was not of the lardaceous kind; indeed, no sufficient time had elapsed for the development of that peculiar change, whether referred to the infecting chancre or to the abscess in the groin.

It is interesting to know that a suppurating bubo of less than six weeks' standing, when aided and abetted by organic disease, may give rise to pyæmia.

#### NORTH LONDON CONSUMPTION HOSPITAL.

EMPHYEMA WITH FETID SPUTUM.

(Under the care of Dr. CHARLES R. DRYSDALE.)

RICHARD DOYLE, aged 27, a pianoforte-maker, entered the hospital at Hampstead on December 1st, 1870. He was single, and had been ill for six months. He had served as a soldier in India for eleven years, and was discharged the service in April 1870. His father died of an accident. His mother was alive and well; but, of a family of eleven children, there were but three now alive. He had a cough, but never any hæmoptysis. He used to weigh nine stone, but, on entering the hospital, only eight. This patient was in the Metropolitan Free Hospital for six months, under the care of Dr. Lomas, who transferred him to Hampstead for change of air, and to be under Dr. Drysdale's care. His illness commenced with shivering fits and fever; and, after the patient had been a month in hospital, an abscess pointed below the fifth rib on the right side; and shortly afterwards there were three fistulous openings into the cavity of the pleura, which subsequently discharged pus very freely. The sputum was very fetid, and was puru-

lent in aspect; and, when the patient coughed, pus exuded in streams from the openings in the right side. The pulse on December 21st was 154. There was complete dullness over the whole of the right back up to the upper borders of the scapula, and in front as far as the clavicle. The breathing at the left apex was harsh, but not in any respect abnormal. At the right apex, a little breathing was heard.

The diagnosis was that of non-tuberculous empyema, with the dangerous complication of the constant access of air into a purulent cavity. The factor of the apartment in which the patient lived was so great, that the other consumptive patients in the hospital complained that, as they passed the door, it made them vomit. Burnett's solution, and also Condy's fluid, did a little good as disinfectants; but neither these nor carbolic acid lotions were powerful enough to prevent the factor. On January 3rd, the respirations were 48; pulse 160. The girth of the affected side was 16½ inches; that of the healthy side, 15½ inches at the level of the nipple. The bowels were regular; the tongue clean. On January 10th, after dressing with Condy's fluid (at the suggestion of Dr. Prosser James, who was consulted by Dr. Drysdale), the pulse fell to 120, and the respirations to 40. The appetite was better. The patient took half a grain of morphia at bedtime, and had a liberal diet. On January 27th, he was again ill and feverish, and the factor was as bad as ever. A small quantity of a solution of nitrate of silver (gr. v to 3i) was injected into the chest, and was followed by relief for two days, the factor and suppuration being lessened. Dr. Drysdale, being anxious that the system of thorough drainage of the cavity should be tried, asked Mr. Berkeley Hill to treat the case in that way. The patient was taken by Mr. B. Hill into his surgical ward; and a drainage-tube was inserted into the chest, whilst carbolic acid dressing was employed. Shortly after this treatment was adopted, the patient was seen by Dr. Drysdale (in March 1871), when a marked improvement was observable. Unfortunately, whether from inhabiting an ordinary surgical ward, or from the results of his own disease, pyemic symptoms arose, and the patient succumbed. Surgical wards are scarcely suitable for such cases. Another patient, a little girl about eight years old, was sent by Dr. Drysdale to Mr. Hill, but went into the Children's Hospital, from the Farringdon Dispensary, in the early part of 1871, to have a quantity of serous fluid in the right pleural cavity withdrawn by means of the aspirator—an operation not unfrequently, it appears, performed in that hospital. The chest was quite full of fluid; and the operation, which was most skilfully carried out by the present house-surgeon of that hospital, has been most successful.

These cases have been mentioned in order to add to the list of those reported in the BRITISH MEDICAL JOURNAL on July 1st, 1871, by Dr. Thorowgood. Dr. Drysdale thinks that such operations are too little performed, and has seen many cases where a fatal issue has taken place, that might, he believes, have lived, if withdrawal of the fluid from the chest had been performed at an early period in pleuritic effusion.

#### ST. BARTHOLOMEW'S HOSPITAL, ROCHESTER.

ERYSIPELAS OF THE HEAD AND NECK, WITH VIOLENT DELIRIUM, TREATED WITH CHLORAL.\*

By A. W. NANKIVELL, F.R.C.S.

J. M., aged 30, was admitted October 28th, 1870, suffering from erysipelas of the head and face, resulting from a wound. The right side of his head and neck was much swollen, and his right eye entirely closed. He was at this time perfectly rational. Next day, the erysipelas had extended all over the head, and down the chest as far as the mammary region. He had a quiet night. In the afternoon, he became delirious, and had 30 grains of chloral at 5.35 P.M.; 40 grains at 6.10 P.M.; 20 grains at 7 P.M.; 30 grains at 7.40; 20 grains at 8.15; 20 grains at 8.30 (he spat it nearly all out, swallowing about 5 grains); 20 grains at 8.45 (of which he only swallowed about 5 grains); 20 grains at 9 P.M. (of which he swallowed about 10 grains). At 9.45 P.M., he was quieter; 30 grains of chloral were put into his mouth, and he swallowed about 15 grains. At 10.45 P.M., he refused all medicine, and 40 grains of chloral mixed with milk were injected into the rectum. At 11.40 P.M., after much persuasion, the patient was induced to take some beef-tea containing 40 grains of chloral. A few minutes after taking the last dose, the man fell asleep till 2 A.M. When seen next morning, he was found to be rather noisy, but quite ready to take food. He was given 30 grains of chloral in the course of the day, after which he slept for three hours. After this date, the man progressed favourably, with the exception that a large part of the skin of the right side of the neck sloughed, and, in consequence, the resulting ulcer took

a long time to heal. We, however, managed to accelerate the healing materially by skin-grafting.

My object in bringing this case before you is to show the large amount of chloral that was taken in a short time without any bad results. The chloral was first administered on October 29th, at 5.35 P.M. The last dose before sleep was induced at 11.40 P.M. During the interval of six hours and five minutes, the patient took as much as 255 grains. As far as I have been able to discover, this is the largest amount of chloral given in so short a time.

#### INJURY OF THE CERVICAL VERTEBRÆ: ANKYLOSIS OF THE ATLAS TO THE OCCIPITAL BONE: DISLOCATION OF THE AXIS: DEATH.

By A. W. NANKIVELL, F.R.C.S.

A. U., aged 37, a labourer on the Government telegraphs, on the evening of December 24th, 1870, had a row with some people in a public house. He was ejected therefrom, and fell headlong down a flight of stairs. He went home to his lodgings, and complained of stiffness in the neck. He resumed his work in the course of a few days, and continued it till February 23rd, 1871. During this time, his fellow-labourers noticed that he was scarcely able to rotate his head. On February 24th, he stated that he did not feel quite well, and would take a few days' rest. This he did. Next morning, not feeling better, he walked to a surgeon, who gave him some medicine. On February 26th, he was found by his fellow-labourers to be much worse, being quite unable to walk. He was carried by them to a surgeon, who sent him here. On admission, his arms and legs were found to be completely paralysed. The muscles did not respond to galvanism. He could swallow with difficulty, and could not speak above a whisper. He died in three-quarters of an hour.

A *post mortem* examination was made twenty-four hours after death. Rigor mortis was well marked. The patient was a well-nourished, strong, healthy working-man. The pleura, lungs, pericardium, heart, liver, and spleen were slightly congested. The left kidney contained numerous cysts, communicating freely with each other, the gland being atrophied. The right kidney was hypertrophied. The brain was healthy. On dividing the medulla oblongata, a bony prominence was felt, partially filling up the foramen magnum. The medulla was slightly softened at the seat of pressure. On removing the portion of skull and part of the cervical vertebræ (which I have here before me), we found that the projection was the odontoid process of the axis. The atlas was partially luxated from the occipital condyles, and rotated about twelve degrees, the left articular process of the atlas being thrown forward and crushed against the skull, yet without fracture. The right upper articulating process of the axis was covered with cartilage, and healthy; the left was bare of cartilage, and the corresponding surfaces of the atlas were in the same state. The ligaments were unfortunately destroyed in removing the specimen.

The interest of this case is due to the length of time that elapsed from the receipt of the injury to the occurrence of any grave symptoms, and to the rapidity with which death came on after the commencement of the fatal symptoms. So rapid a death appears, in all probability, to have been caused by some sudden giving way of some of the ligaments, thus allowing the odontoid process to slip up into the foramen magnum, and so cause the paralysis.

#### BRADFORD INFIRMARY.

CASE OF CONGESTION OF SPINAL PIA MATER: COLD: COUNTER-IRRITATION: ARSENIC: CURE.

(Under the care of Dr. NICOL.)

THE notes have been taken by Mr. Roberts.

J. M., a "striker" (using a heavy hammer), aged 23, married, was admitted on June 29th, 1871. He had suffered for some time from various dyspeptic symptoms, but these disappeared under treatment. A few days ago, he was seized with pains along his back, a feeling of girding about the loins, and sweating over the spine. His gait became excessively irregular, so that he could hardly walk; and control of the sphincters became deficient. He had been indulging in venereal excesses. He was in the same state on admission, and was very unsteady when his eyes were shut. A spot, tender both to pressure and to the cold sponge, could be detected at the top of the sacrum. There was some fibrillation of the glutæi muscles. The irregular gait appeared to be from spasmodic action of some muscles, especially the abductors of the hip. His legs appeared perfectly strong as regarded individual motions. He was tolerably well in other respects. He was ordered to have a series of small blisters applied to the sacral and lumbar regions; to have a cold hip-bath night and morning, and two minims of liquor arsenicalis three times a day.

July 14th. The treatment had been steadily continued. Control of

\* This case, and the following one, were read before the West Kent District Meeting of the South Eastern Branch.

the sphincters had been regained, and there was rather want of confidence than unsteadiness in his gait.

July 31st. He had had slight dyspepsia, but was now able to be discharged, cured.

September 12th. He is at his work, and can walk well.

## THE NOSOLOGY AND TREATMENT OF DIARRHŒA, CHOLERINE, AND ASIATIC CHOLERA. (Concluded.)

NORWICH AND NORFOLK HOSPITAL.

SPEAKING generally, Dr. EADE says that he has always been in the habit of treating epidemic autumnal diarrhœa by astringents; and that he has little experience of aperients in this disease, with the exception of rhubarb; but, as this has never been given uncombined with ammonia or aromatics, it is doubtful if the latter have not often been the really efficient agents—especially as, in many of the milder cases, the force of the disease has spent itself before the slowly acting rhubarb has begun to have any decided effect. In certain special cases, where offending food or drinks, or a loaded stomach or bowels, appear to be connected with the attack, he has first tried to remove these causes; but, as nature seems generally to have most thoroughly carried off all possible causes of offence by the time medical assistance is obtained, and as it seems impossible that an epidemic cause, which may affect simultaneously some hundreds of individuals, should be of a dyspeptic character, he has generally been satisfied to treat the diarrhœa and the other symptoms directly. Some years ago, in cases of severe autumnal diarrhœa, he always commenced the treatment with three to six grains of calomel; but of late years he has much less frequently administered such a dose. The medicine on which recently he has mainly relied is the dilute sulphuric acid, given alone in water, or combined with laudanum, according as much pain has or has not been present. In the majority of cases, its action has been speedy and effective, and such as to leave little to be desired. In other cases, the compound kino powder, or tinctures of catechu and opium, with or without chalk or soda or sal volatile, have answered completely. He has also found the very best results from the administration of pills containing a quarter-grain each of nitrate of silver and of opium. When bile or colouring matter has ceased to be discharged, then direct astringents have seemed to be less useful; but the dilute sulphuric acid in full doses has still often appeared to act well, and the case has speedily come to an end. So also, at this stage, aromatics, when the stomach will retain them, have been grateful and helpful—such as ammonia, ginger camphor, compound tincture of rhubarb, or brandy and water. In the stage of exhaustion, he has given brandy, with laudanum if cramps continue; but at this period remedies taken into the stomach have seemed to be of less avail, to be often immediately vomited, and, even if retained, scarcely absorbed. Ice sucked, and hot turpentine stupes, or hot applications externally, with frictions, have then appeared to be of most service. In fairly healthy adults, autumnal diarrhœa or English cholera, even when very severe, rarely (in his experience) kills; and as the attack is sudden, so generally the illness is not very long, and relief is usually obtained by either of the above remedies. It is in the unhealthy, or those with some constitutional or visceral fault, that failure occurs; and in these cases it is necessary to employ treatment with special reference to the peculiarities of the case. In old people with feeble digestive systems, and in whom absence of colour in the stools is an early symptom, astringents have often failed; and he has found an artificial gastric juice, such as dilute nitro-muriatic acid and liquor of pepsin, with a little strychnine added, to be sometimes extremely useful. In infants, in whom the great mortality of an autumn epidemic occurs, the cachectic or scrofulous habit quickly shows itself. Amongst the numerous patients at the Child's Hospital in Norwich, he constantly finds a vitiated bowel-secretion to be the real cause of the intractableness of the diarrhœa; and in these cases, along with the usual alteratives, acids, and the sulphuric, and especially the nitro-muriatic, do more good than direct astringents; the diet being at the same time improved and carefully regulated, and extract of meat or Liebig's food being given as they can be borne. During an epidemic, great care is needed in the diagnosis of infantile diarrhœa, for, though the immediate exciting cause is probably the same in all, yet many other disturbing agents may be in operation. Moreover, in many cases, even where, from day to day, the digestive and bowel function is lost, and only just carried on sufficiently well for nutrition, that the instant the secretory processes are deranged by shock of any kind, the nutritive equilibrium is at once overthrown, and the frequent profuse discharges, void of healthy colours and solids, at once appear.

As to the nosology of the disease, Dr. Eade thinks we may trace an

analogy with the ordinary periodical "bilious attacks" or sick headaches commonly seen in women and in men too—i.e., attacks of sudden headache and vomiting of "bile", which are plainly not due to biliousness at all (indeed, often occurring in the anæmic and non-bilious), but which are really nervous paroxysms or explosions—veritable fits on a small scale—in which there is not an excess of nerve-force, but its irregular action, and probably absence of supply to the gastro-hepatic system; and hence a *de facto* diarrhœa of bile and mucus, ejected upwards instead of downwards. Those who are victims of these attacks know well that rest in bed for twenty-four hours and abstinence are the main remedies for these seizures; that neither purgatives nor astringents help them; but that tea (a nervous stimulant) gives them some relief; and that effervescing soda-draughts, and ice sucked gradually, are often very grateful. Summer choleraic attacks, when the purging has not been so profuse as to render an attempt at checking this symptom at once imperative, have sometimes seemed to have subsided as well and quickly with this kind of treatment as with any other.

Dr. Eade's experience of true cholera is neither large nor recent; but the symptoms of cholera, cholerine, and epidemic diarrhœa, have always seemed to him to differ more in degree than in kind—all appearing to be due to some sudden alteration of the innervation (of the nature of a paralysis) of the gastro-hepatic and intestinal mucous surfaces, whether produced by the reception into the body of some specific poison, or by some special influence exerted upon the visceral nerveplexuses and ganglion by the rays of the autumnal sun.

## MANCHESTER CLINICAL HOSPITAL.

ANKYLOSIS OF THE HIP-JOINT, WITH MALPOSITION OF THE LIMB: SUBCUTANEGUS SECTION OF THE NECK OF THE FEMUR.

By JAMES HARDIE, M.D., Surgeon to the Hospital.

MARTHA NEWHAM, aged 22, had rheumatic fever in the beginning of 1868. For about a fortnight, the affection involved nearly all the larger joints, and after this it continued in a subacute form in the right hip and knee. She was unable to leave her bed for four months, and for two months after that could only take exercise in a Bath-chair. At the end of May, she came under the care of Mr. Greenwood, of Newark, who has obligingly furnished me with a few notes of the condition and progress of the case while under his care. At that time there was no malposition of the limb, but the hip- and knee-joints were almost immoveable. All the acute symptoms had disappeared, and Mr. Greenwood succeeded in restoring perfect motion to the knee, by the forcible rupture of false bands under chloroform. A month afterwards, he tried a similar operation on the hip, "but not with the same result, although motion was most certainly improved." Shortly after this, the patient left Newark. It would appear that she could not continue to exercise the joint so as to maintain the improvement which had been effected; but that from this time the thigh became flexed on the pelvis, and was habitually kept in that position. It had remained in the same condition ever since, and the patient had not suffered in any way except from the inconvenience of the deformity.

When the patient came under my notice, the thigh was flexed on the pelvis to an angle of 100 deg. with the spine, and was neither adducted nor abducted. When she stood erect, so as to straighten the spine, the foot was raised fully twelve inches from the floor. She rested and walked on the anterior part of the right foot. This occasioned great arching of the spine, and her gait was awkward in the extreme. She could walk without support, but not for more than about a quarter of a mile at a time, without great fatigue and pain in the back. The thigh could not be moved without moving the pelvis also.

June 10th, 1871.—Under chloroform, forcible efforts were made to straighten the limb by breaking up the adhesions. These being perfectly unavailing, I performed Mr. Adams' operation of subcutaneous section of the neck of the femur. The puncture was made at the spot recommended by Mr. Jessop of Leeds, about an inch behind the great trochanter on a level with its tip. I experienced considerable difficulty in completing the division of the bone, as the saw very frequently became locked. This I attribute in great part to the puncture being placed so far back. There is thus some difficulty in getting the blade placed comfortably in front of the neck of the bone. I would, therefore, advise that the knife be entered half an inch above the tip of the trochanter, and carried directly down to the bone, making a straight track from this aperture to the front of the neck. I had previously found, in experimenting on the dead subject, that the saw worked better from the point, and regretted that I had mistrusted my experience when I came to operate on my patient.

When the bone was divided, the limb at once became free, but was

kept from becoming quite straight by the rigidity of the tendons of the adductor longus and long head of the rectus muscles. These were divided with a tenotome, and the limb then assumed a perfectly straight position. A weight was attached and hung over a pulley.

There was rather free hæmorrhage from the puncture, but not enough to cause any trouble. A piece of lint dipped in carbolated oil was applied and bandaged on.

For the first few days there was a little oozing of blood from the wound, but the latter was not much disturbed. On the 19th, it had not healed, and a morsel of dry lint was placed on it. On the 28th, it was found closed. The weight was removed on the 19th. No complaint whatever was made by the patient so long as she was left undisturbed, but the least attempt at moving the limb gave great pain. This was tried on several occasions after the weight was removed; but it was borne so badly that the hope of succeeding in forming a joint was abandoned. The patient was therefore simply kept at rest in bed till it was supposed that union of the osseous surfaces had taken place. She was allowed to walk about after seven weeks, and in a short time could do so with great ease, with the help of a crutch and stick. The patient has now gained greatly in the use of the limb. She has discarded the crutch, and can rest nearly her whole weight on the one leg. Both legs are of exactly the same length, and the right is firmly united in a straight line with the trunk. The patient expresses much satisfaction with the result of the operation.

#### LEEDS GENERAL INFIRMARY.

##### ADAMS'S SUBCUTANEOUS OPERATION FOR DIVISION OF THE NECK OF THE FEMUR.

Mr. JESSOP has favoured us with the following notes.

A fortnight ago I readmitted my second case of subcutaneous division of the neck of the femur, for the purpose of carrying out more effectually the movements required for the due establishment of a false joint. On admission, when standing upright, the patient could plant the ball of the great toe upon the floor, and could bear fully one half the weight of her body upon the limb, which on measurement was two and a half inches shorter than the sound one. She usually walked with one crutch, but occasionally required two. She could flex the thigh so as to form a right angle with the body without pain; any attempt to force the knee nearer the body produced resistance and pain. On September 20th I placed her under chloroform, and moved the limb very freely in all directions. During the movements, several audible snaps took place, as fibrous bands gave way. She is much benefited already by this, and can move the limb more freely.

The first of my two cases (Margaret Rudderam), published in the JOURNAL for January 14th, 1871, walks well (but with a limp) without any assistance, and has very free mobility of the limb.

##### CASES OF SLOUGHING OF THE SCROTUM AFTER TAPPING FOR HYDROCELE.

(Under the care of MR. JESSOP.)

CASE I.—J. H., aged 25, came to the Infirmary for the first time on April 14th, 1871. It was seen, on examination, that he was suffering from a hydrocele on the right side. This, which was not of large size, was tapped with a small (No. 2) trocar, and he went home. He came again three days afterwards (April 17th). He stated that he had suffered much since the tapping, that he had felt cold and shivered slightly, that he had lost his appetite, and that he was very thirsty. He was then admitted as an in-patient. On looking at the scrotum, a gangrenous patch, the size of half-a-crown, was seen at the site of the puncture, and it was evident that there was suppuration in the tunica vaginalis. He was put to bed, and wine, beef-tea, and milk were administered freely. He also had a grain of opium twice daily, and poultices to the scrotum. The sloughing, however, spread, till at the end of a week the whole scrotum was destroyed, and both the testicles with the cords as high as the external ring were exposed. At first sight, it looked as if some plastic operation would have to be performed to cover the exposed testicles, but it was determined, in the first place, to give him time. He remained as an in-patient till June 24th, when the testicles were almost covered by skin, which was drawn down by the contraction of the granulation from the abdomen and groins. He was then made an out-patient. He has lately presented himself with the wound entirely healed, and the testicles not at all exposed.

CASE II.—J. B., aged 71, was admitted as an out-patient on July 7th. He was suffering from a large hydrocele on the right side. This was tapped with a trocar the same size as that used in the previous case, and the patient went home. At the end of a week (July 14th) he

again presented himself. All the anterior part of the scrotum was then gangrenous, and he was in a very feeble and feverish condition. He was admitted as an in-patient and treated like the previous case. The gangrene spread so as to destroy the entire scrotum, extended to the groins, and implicated some patches of skin on the upper part of the thighs. Notwithstanding the administration of good food and plenty of wine, no efforts towards repair took place, and he died, exhausted by the suppuration, on August 12th.

#### SWANSEA INFIRMARY.

##### POPLITEAL ANEURISM TREATED BY COMPRESSION.

Under the care of Mr. J. G. HALL.

JOHN JONES, aged 29, a striker in a blacksmith's shop, was admitted into the Swansea Infirmary, May 3rd, 1871, with popliteal aneurism. He first complained of pain in the leg, and observed a small tumour in the popliteal space about five months before his admission. It gradually increased in size until his admission, when the tumour appeared as large as a small orange. On May 5th, Signoroni's tourniquet was applied to the femoral artery in the groin, about two inches beneath Poupart's ligament; but, as the pressure of the tourniquet gave much pain, he took four grains of compound soap pill every three hours. Continual pressure was kept up for the first three or four days by changing the position of the tourniquet; after which he could not bear the pressure so continuously, but kept it on during the day and left it off at night. The pulsation did not fairly cease until ten days or a fortnight after the first application.

## REVIEWS AND NOTICES.

LECTURES ON THE PRINCIPLES AND PRACTICE OF PHYSIC. By SIR THOMAS WATSON, Bart., M.D., F.R.S., etc. Fifth Edition. London: Longmans, Green, and Co. 1871.

AT length, after many months of expectation, we have the satisfaction of finding ourselves this week in possession of a revised and enlarged edition of SIR THOMAS WATSON'S celebrated Lectures. It is a subject for congratulation and for thankfulness that Sir Thomas Watson, during a period of comparative leisure, after a long, laborious, and most honourable professional career, while retaining full possession of his high mental faculties, should have employed the opportunity to submit his Lectures to a more thorough revision than was possible during the earlier and busier period of his life. Carefully passing in review some of the most intricate and important pathological and practical questions, the results of his clear insight and his calm judgment are now recorded, for the benefit of mankind, in language which, for precision, vigour, and classical elegance, has rarely been equalled, and never surpassed. With the age of Nestor, Sir Thomas Watson has retained and even improved upon the silver-tongued eloquence in which he was alike wont to clothe his wise and careful judgments. In an epilogue at the end of the second volume, the author expresses his obligations to Dr. George Johnson "for his friendly assistance in re-editing the Lectures". The revision has evidently been most carefully done, and the results appear in almost every page. Here and there a large portion of a lecture has been rewritten, and considerable additions have been made to others. The additions amount, in the whole, to upwards of one hundred pages; and this notwithstanding the omission of the lectures on Diseases of the Eye—a subject which the author probably considers too extensive and too special to admit of satisfactory discussion during a course of lectures on medicine. The only disease of the eye to which reference is made in the present edition is iritis, and this mainly to illustrate the influence of mercury upon the syphilitic form of the disease.

The two large and handsome volumes are so rich in new and interesting materials as to embarrass us in our attempt to make selections for quotation and comment. On the present occasion, we shall restrict ourselves to the first volume, reserving for a further notice the contents of the second.

The profession will be interested to learn that the important subject of treatment has throughout the whole series of lectures been revised with scrupulous care, the directions now given being in strict accordance with what may fairly be considered the teachings of modern scientific medicine. The subject of Blood-letting, general and local, is discussed at considerable length, and the rules for its employment appear to us singularly lucid. The subject is introduced thus: "In times past, no doubt, bleeding was apt to be employed inopportunistically, to be misdirected, or to be pushed beyond its proper and safe limits; but of late medical practice has rushed to the very opposite extreme—

which of the two mistakes is calculated to be most injurious to the human family it would not be easy to estimate. I remember the time when a surgeon who found a man lying in the street in a fit was blamed and abused by the bystanders if he did not at once open a vein in his arm. To do this now-a-days would be to incur the charge of murdering the man." After discussing the subject of local bleeding, the influence of which is rendered clear by several happily chosen illustrations, Sir Thomas goes on to say: "I hold it then to be certain that, in many cases of inflammation, *local bleeding* is a powerful, a safe, and therefore a proper and eligible remedy; and that its beneficial operation consists in diminishing, by direct withdrawal or by diversion, the quantity of blood distributed to the part or organ inflamed. But what of *general bleeding*—what of venesection in particular—as a remedy for inflammation? It is in this matter I am bound to admit, that great mistakes have formerly been made; that a potent agency has been misdirected."

After a full and very interesting discussion of the subject, the conclusion arrived at is thus expressed. "I hold it then to be certain that, for some special morbid constitutions, which inflammation may or may not accompany, venesection is a potent and life-preserving remedy; that there are many exigencies for which it is not only safe to employ, but unsafe and unpardonable to withhold it. I shall have to return to this subject hereafter, but I may repeat now in brief terms that the condition which cries out for and obtains relief so signal and immediate from phlebotomy, may be described as that of great and often sudden engorgement and distension of the vessels that carry black blood, of the systemic veins, of the pulmonary artery, and especially of the right chambers of the heart. In this embarrassed condition of the circulation, with so unequal a distribution of blood in the two different systems of vessels, it is the veins that require emptying, not the arteries. As the tension of the stretched and almost paralysed right ventricle is lessened, the hollow muscle again becomes capable of contracting upon and propelling its contents, the clogged lung is set free, the functions of the oppressed brain are eased and retrieved, and the balanced play of the heart and lungs is restored. This, as it seems to me, is the true philosophy of blood-letting in disease, approved by reason and fortified by experience. The credit of having been among the first to rectify the vaguer notions that formerly prevailed on the subject is fairly due to Dr. Markham."

The well-known lecture on the Different Modes of Dying has always appeared to us to be one of unusual interest. In the present edition, we recognise two additions which render the lecture still more interesting and complete. The arrest of the circulation through the lungs in cases of death by apnoea is thus explained. "It had been ascertained by various trustworthy observers that, if the thorax of an animal which has been suddenly strangled by a tight ligature placed upon its windpipe, be examined immediately after death, the lungs are always found empty of blood, while there is a vast engorgement of the right heart, of the great veins, and of the pulmonary artery up to its minutest ramifications. These are the plain and unquestionable facts of the case. They show that some opposing power must have been called into play, more than equal to the propelling power of the right ventricle of the heart. Now, such a power—and it is the only conceivable one—actually exists at the very place where the venous current meets with its curb; and it consists in the firm contraction of those muscular fibres of the minute arteries, the function of which it is to regulate the blood-supply in accordance with the varying requirements of the part. This function, again, is determined by those unsleeping sentinels the vaso-motor nerves. Were it allowable, for the sake of illustration, to impersonate the vital forces concerned in this marvellous adaptation, we might liken the process to the intelligent stopping of the traffic on an obstructed line of railway by a backward telegram. Or take another illustration. The blood passes into the pulmonary capillaries in order that it may be aerated. Whenever this process of aeration is suspended, a nervous signal is sent from the capillaries to the minute pulmonary arteries, enjoins their contraction, and thus stops the blood-stream. The purpose of the arterial spasm is to prevent the flow of blood into the pulmonary capillaries upon the cessation of the function of respiration. If the stop-cock of a gas-burner could be made self-acting, so as to maintain at all times a constant and exact relation between the supply of fuel and the rate of combustion, and so as further to turn off the gas and prevent its escape when by any accident the flame is extinguished, that would represent, with sufficient accuracy, the working of the living arterial stop-cocks in the lungs."

The other addition to this lecture, to which we just now referred, consists in the account given of embolism and thrombosis in the pulmonary artery, as a means whereby the circulation may be brought permanently to a stand. "If the obstruction be complete, death may be instantaneous. If the vessel be not perfectly sealed, extreme dyspnoea, with pallor and faintness, comes on at once, and the patient dies within a period varying from a few minutes to several hours. It is remark-

able that an impediment to the supply of blood to the lungs through the pulmonary artery, causes dyspnoea as urgent as an impediment to the supply of air to the lungs through the air-passages. Physiologically, this is explicable by the want, common to both cases, of aerated blood by the system, expressing itself in the chemical cry from the famishing tissues for the indispensable oxygen. What is peculiar to this mode of dying is, that the circulation is stopped, yet not by asthenia; and the function of respiration is suspended, yet not by apnoea. Death does really, in this case, begin in the lungs; and the mode of dying may, with literal accuracy, be called death by *pulmonary asphyxia*, or pulselessness in the pulmonary artery."

In an earlier part of the lecture attention is drawn to the fact that the literal meaning of the word *asphyxia* is pulselessness, and that this term is inaccurately, though not uncommonly, employed to designate death by suffocation, of which mode of death the term *apnoea* (privation of breath) is justly expressive. It is very important to get rid of unsuitable terms which are apt to warp our notions concerning the real nature of the things which they are intended to express. The terms *asphyxia* and *apnoea* are both needed to express different pathological states; they must not be confounded or used indiscriminately, the one for the other.

Passing on to Diseases of the Nervous System, the subject of *aphasia* is discussed at some length; and the various speculations and opinions to which this intricate problem has given rise are set forth with characteristic clearness, reference being made to the writings of Drs. Bastian, Bateman, Hughlings Jackson, Maudsley, Moxon, William Ogle, Sanders, etc.

The relation between cerebral hæmorrhage and hypertrophy of the left ventricle is explained more completely and satisfactorily than in any previous systematic treatise with which we are acquainted. It is an acknowledged fact that cerebral hæmorrhage and hypertrophy of the left ventricle are often found associated; but it does not necessarily follow that the relation between them is always that of *cause and effect*. In only one class of cases, to be presently referred to, is this the actual relationship. Hypertrophy of the left ventricle is most frequently associated with other structural changes in the heart, with valvular defect, which involves an impediment to the circulation, acting backwards through the right heart and the veins upon the cerebral vessels. Many cases of apoplexy occurring in persons who have previously had cardiac hypertrophy are cases of this kind. The brain-affection is dependent in part upon disease of the heart, but not upon preternatural strength of its left ventricle. The heart acts injuriously upon the brain backwards through the veins, and not through the arteries.

But there is another reason for the coincidence between cerebral hæmorrhage and hypertrophy of the left ventricle; and here the arteries are concerned. When the arteries of the brain are rendered frangible by fatty degeneration or ossific change, the commencement of the aorta is usually found to be the seat of similar alterations. This condition of the arteries impedes the onward movement of the blood, and hypertrophy of the ventricle is a natural compensation for the morbid state of the aorta. The strength of the left ventricle, therefore, in such cases, is not a true measure of the force with which the blood is driven into the distant arteries; on the contrary, it is a measure of the difficulty with which the blood is circulated through the primary branches, and, therefore, through the whole system of the arteries. So that in these cases, instead of regarding the cerebral hæmorrhage as the effect of the hypertrophy, the apoplexy and the hypertrophy should rather be looked upon as concomitant effects of the same cause; viz., of the disease pervading the arterial tree. "The hypertrophy of the left ventricle is a consequence of the diseased condition of the aorta at its mouth; the cerebral hæmorrhage is a consequence of a like diseased condition of the arteries of the brain." Sir Thomas goes on to say: "Yet there is a form of hypertrophy which is very likely to prove a direct cause of cerebral hæmorrhage. Of Bright's disease, when chronic, hypertrophy of the left ventricle, without valvular or other disease of the heart or great arteries to account for it, is an almost constant accompaniment and consequence. How is this?" Referring to Dr. Johnson's paper on hypertrophy of the muscular walls of the minute arteries, Sir Thomas explains that "in Bright's disease the blood is unpurified; and while the minute arteries in various tissues—the skin, the muscles, the brain, and other parts—oppose its passage, the left ventricle beats with increased force to drive it onwards. The result is hypertrophy of the muscular fibres of the arteries and of the left ventricle of the heart. Apply this doctrine to the brain. The arterial stop-cocks resist the passage of the unpurified blood into the capillaries; the strong left ventricle strives to force on the blood; the resulting distension of the systemic arteries is indicated by the full and hard radial pulse, and by the evidence of increased arterial pressure afforded by the sphygmograph. There is thus excessive pressure on the whole of

the arterial pipes between the stop-cocks and the forcing pump, and in the struggle between the two contending forces a minute artery in the brain may be broken, and so cerebral hæmorrhage may occur.

The lecture on Chorea has been considerably enlarged; and the interesting question of the relationship between cardiac disease and chorea, including the doctrine of embolism in the cerebral capillaries, is fully discussed.

Amongst the novelties in this volume, we find the two diseases *Locomotor Ataxy* and *Wasting Palsy* concisely but lucidly described.

Diphtheria receives a full and complete exposition; and then the question is raised, "Is the disease which has for so many years been called in this country *the croup*, and which is attended with a membranous exudation in the larynx, anything else than diphtheria? I believe it is not. I believe that, ever since Dr. Home's pamphlet on *Croup* was published in 1765, our writers on the subject have given us the history, the symptoms, and the treatment of acute catarrhal laryngitis, with the morbid anatomy of diphtheria; thus confounding together two diseases very different in themselves, and requiring very different treatment." Then, after a brief argument, the conclusion is thus stated: "You will understand that I give in my adhesion to the opinion that croup, accompanied by false membranes in the larynx and trachea, is always diphtheria, whether in the child or in the adult; and that simple laryngitis is never associated with the exudation of false membrane."

[To be continued.]

TEXT-BOOK OF SKIN-DISEASES. By Dr. ISIDOR NEUMANN, Lecturer on Dermatology in the University of Vienna. Translated by ALFRED PULLAR, M.D., Physician to the East London Hospital for Children. London: Robert Hardwicke. 1871.

It is observable amongst recent dermatologists in this country, that their work, admirable in other respects, lacks that scientific basis, that dependence on microscopical research, which the difficulty and obscurity of skin-diseases often demand. Of the Vienna school, rendered famous in the eyes of dermatologists by Hebra, this cannot be said; and the volume now before us is a further proof of the high character of its work. Dr. NEUMANN is at present Lecturer on Dermatology in the Imperial University of Vienna, and was for many years the pupil and fellow-worker of Professor Hebra in the General Hospital of that city. The author, in the first place, very naturally, but also from independent observation, has adopted many of Hebra's views. But the value of the treatise is by no means to be limited to a representation of the views and practice of this distinguished professor; for Dr. Neumann has for many years worked laboriously and with marked success, more especially at the anatomical changes in skin-diseases; and the results of his labours are embodied in the present volume. In publishing the results of his own microscopical work and practical experience, the author gives evidence of an intimate knowledge of the work of others. The pages of the book are richly illustrated with woodcuts, which have been beautifully executed by Dr. C. Heitzmann. He has thus produced a text-book which, beyond all others, places the reader *au courant* with the scientific dermatology of to-day.

Such is the style of book which Dr. PULLAR presents to the profession in an English form. The translator, in fulfilling his task, had the advantage of obtaining from Dr. Neumann for translation the sheets of the second edition as they passed through his hands, and also casts of the original woodcuts. Dr. Pullar has thus been able to publish Dr. Neumann's work shortly after the appearance of the German edition. The volume, although well got up in other respects, in shape will not commend itself to English readers; but this is a small matter, and is, we imagine, due to the size of the woodcuts, which are produced, as we have said, from the originals. Dr. Pullar is to be congratulated on the quality of the translation, which is free from verbiage and is evidently meant to be as literal as possible, without interfering with the phraseology of our own language. He equally deserves the thanks of the profession for producing a work in an English form, which pre-eminently above all others with which we are acquainted comprises a brief and complete account of exact modern research in dermatology.

BEQUESTS, ETC.—The Hon. Caroline Mary Vernon Harcourt, of Newsells Park, Herts, has bequeathed £1000 to the Royal Hospital for Incurables, Putney.—General Thomas M. Taylor, of the Indian Army, has bequeathed £50 to the Middlesex Hospital.—The Manchester Royal Infirmary has received £981, and St. Mary's Hospital £490, under the will of Miss Hannah Ball, of Bowden.—Mr. W. Welch has bequeathed £200 to the Children's Hospital, Birmingham.—The Sheffield Public Hospital and Dispensary has received £100 (less duty) under the will of Mr. Thomas Fisher, of Norwood Grange.—E. N. has given a third £1000 to St. Mark's Hospital for Fistula.

## REPORTS AND ANALYSES.

### CHAPMAN'S ENTIRE WHEAT-FLOUR.

LAST year, at the Newcastle meeting of the British Medical Association, a preparation was very prominently brought under the notice of our members by a well known hospital physician, which he strongly recommended as a dietetic article. It consisted of a very thoroughly ground and careful preparation of wheaten flour, in which the views of Brinton and others of the best dietetic writers have been followed, by retaining the entire nutritive value of the grain. It is a very thoroughly ground whole meal. Brinton, Lankester, Letheby, Mège-Mouries, and others, agree that in the ordinary grinding of wheat, by throwing away a large proportion of the phosphatic constituents contained in the outer envelope, we do virtually waste a large portion of what is most valuable. Nor, indeed, can there be any question of the dietetic importance of the earthy phosphates, and of the cerealin which is thus wasted. In ordinary whole meals, however, they are present in a form which is mechanically irritating to the alimentary canal; and for this, among other reasons, brown bread, for example, has never come into universal use. This objection is removed by Chapman's process. Analysis has shown that the flesh-forming gluten and the bone-forming phosphates are present in Chapman's Entire Wheat-Flour in unusually large and important proportions; but it is free from any mechanically irritating effect even upon weak digestive organs. The value of such a meal is very obvious; and it would be a national advantage that it should come into universal use.

### VACCINATION-SLEEVE.

MR. W. MILLER, of Leicester Square, has devised a sleeve for protecting the arm from friction during the process of vaccination. A perforated zinc shield, formed somewhat in the shape of an arch, passes round two-thirds of the arm, the remaining third being encircled by a band made of waterproof cloth. To the upper part of the shield is attached a series of tapes for fastening to the dress and round the neck respectively.

### BUNION-SPRING.

A VERY light, ingenious, and effectual little instrument under this name, for the relief of bunion, has been manufactured by Mr. W. Miller, of 29, Leicester Square. The instrument consists, as will be seen in the diagram, of two pads, one of which presses the great toe

outwards, whilst the second presses against the second toe, which forms a fulcrum for the instrument to work upon. These pads are acted upon by wire-springs passing over the instep. That marked A is the acting spring; the other is merely added for the purpose of fastening and steadying the instrument. To the ends of these springs are affixed ribbons, which, when the instrument is applied, are passed round the foot and fastened like a sandal. The instrument is brought into action by drawing the ribbon attached to the spring A as tight as can conveniently be borne. This instrument is a great improvement on the more cumbrous and costly and less efficient instrument for the purpose, hitherto in general use, and figured in the handbooks of orthopaedics.

THE Subscriptions to the Association for the year 1871 became due in advance on January 1st. All which are not already paid, should be forwarded to the General Secretary, Mr. T. Watkin Williams, 13, New Hall Street, Birmingham; or to the Secretaries of Branches.

## BRITISH MEDICAL JOURNAL.

SATURDAY, OCTOBER 14TH, 1871.

### MEDICAL RELIEF OF THE POOR.

THE question of hospital out-patient administration has once more come prominently before the public. In the medical profession itself it has been for some time a subject of continued debate. In one form or another, it has been constantly under discussion for years past; and a reference to the pages of the JOURNAL will show that neither at our Branch meetings, nor at our great central gatherings, has it been passed over in silence. But it is only occasionally that it assumes a shape which attracts public attention, and secures for it a place in the daily newspapers.

On the 30th ult. and 4th inst., the Rev. Mr. Kitto addressed two letters to a public paper, in which he pointed out clearly the abuses of our out-patient system, and suggested various remedies. The cue thus given has been followed by other correspondents, and the subject has been considered from several points of view. All who are interested in the question will follow the discussion with pleasure. But there is one circumstance to which we desire to draw special attention, and it is this. In his second letter, Mr. Kitto announces that the out-patient department of the Poplar Hospital has been closed altogether. This is both a very important and a very significant fact. It is very significant, because it shows the gathering strength of public opinion; and it is very important, because it is the first step in a course which we believe, with some modification, will sooner or later have to be followed by all the hospitals.

The out-patient departments of our hospitals are of comparatively recent development. Before the alteration of the Poor-law in 1834, they existed only on a very limited scale. It was the odium which attached to the new Poor-law which led to their rapid growth, and now they have become so efficient and so popular that they attract a great number of persons who have no claim upon charitable relief of any kind. But such a state of things is unjust towards the medical profession and demoralising to the applicants themselves; and this it is which forms the double aspect of the abuse which is now engaging the attention of the public. The public have an interest in upholding the moral character of the population, and in seeing that their charitable gifts are not misapplied; and the medical profession has to guard itself against giving gratuitous attendance to those who are well able to pay for it.

But the Poor-law of 1834 has now been amended, especially in regard to the treatment of the sick. It bids fair to become more like what it ought to be, a great national charity administered in a spirit of wise and far-seeing economy. It is now no hardship that pauper patients should be expected to apply to their parish doctor; and we are all agreed that those who can afford to pay for medical attendance ought to be encouraged to be self-reliant. But if these two classes were subtracted from the crowds who now throng our out-patient waiting rooms, only a comparatively small balance would remain.

Now the authorities of the Poplar Hospital seem to have judged that in their own case this balance would be so small that they were justified in shutting up their out-patient department altogether; and no doubt they have judged rightly. As long as our hospitals continue to offer almost indiscriminate relief to all comers, so long will there be among their out-patients many unsuitable applicants. "Whatever you pay a man to do," says Archbishop Whately, "that he will do; if you pay him to work, he will work; and if you pay him to beg, he

will beg." This is a principle which holds good with regard to other payments besides those which are made in hard cash. If men are bribed to be dependent by the offer of gratuitous relief, they will rapidly become dependent; and this is the evil which our present out-patient departments are in danger of producing, if they have not already brought it about.

It is to meet this evil that the authorities of the Poplar Hospital have adopted the vigorous measure to which we have alluded, and closed the doors of their out-patient rooms altogether. But they could hardly have acted as they have done unless the neighbourhood had offered facilities whereby the poor could receive medical relief on terms suited to their wages. The "Poplar Medical Association" has existed for thirty years, and has taken firm root in the district. It is in effect a provident dispensary; and here those who are above the grade of paupers, but who are yet unable to pay the charges of a local practitioner, can obtain good medical attendance and medicine on payment of a few pence per week.

In both the points put forward by Mr. Kitto, we believe him to be advocating the soundest principles of reform. We want more provident dispensaries to meet the requirements of the industrious poor; and we want to see the out-patient departments of our hospitals reduced to something like the limits which they occupied before the revision of the Poor-law in 1834, and their benefits restricted to those applicants who properly have a claim upon charitable relief.

### VACCINO-SYPHILIS.

WE have received from Dr. Cheadle of St. Mary's Hospital, London, the following details bearing upon this highly important subject.

In March last a strong healthy girl, aged 24, was vaccinated with lymph procured from one of the London hospitals. A fortnight afterwards she came to consult Dr. Cheadle about the state of her arm and her general health. He found great redness and tenderness around the seat of vaccination, and the arm was much swollen, even below the elbow. The vesicular marks—four in number—had only partially healed, but there was nothing suggestive of syphilis in the appearance of the sores. The constitutional disturbance was no more than naturally resulted from the inflammatory action going on. The patient went out of town, and he did not see her again for nearly five months, when she again consulted him about her arm, which still troubled her. On examining it, he found the site of each vesicle exactly occupied by a circular tubercular elevation of a dull red colour with a bronzy tint; it presented, in fact, the exact, the perfect, type of a tubercular syphilitide. The surrounding parts were tender, somewhat swollen, and hard, the immediate neighbourhood of one tubercle, larger than the rest, especially so; and this elevation was also softer to the touch and more gelatinous in appearance, as if on the point of breaking down into ulceration. The patient told him that she had been strong and well up to the time of vaccination, but that she had been ailing ever since, troubled with headache, and without appetite. Her face was of the muddy complexion suggestive of syphilitic cachexia. Dr. Cheadle learnt that the vaccination "sores" remained open for several weeks after he had seen them; but there had been no sore-throat, nor any eruption on any other portion of the body.

Fifteen grains of iodide of potassium were ordered to be taken in decoction of sarsa three times a day, and when he saw the girl again three weeks afterwards, the improvement which had taken place was most remarkable. The tubercles had nearly disappeared; the large one, which had threatened ulceration, having healed with the rest. The tenderness and hardness of the surrounding parts had gone; appetite and the feeling of health and strength had returned. At this time (three weeks ago) the patient, thinking herself entirely recovered, left off taking the medicine, and the tenderness of the part and the cachexia have in some degree returned. The eruption, which had been disappearing rapidly, remains in *statu quo*—slight, but stationary.

Is the eruption, Dr. Cheadle asks, in this case of syphilitic origin?

Its appearance, its course, the accompanying cachexia, and the rapid recovery under iodide of potassium after it had existed four or five months without change except for the worse, form strong presumptive evidence in favour of such a conclusion. He has had special opportunities at the Hospital for Sick Children for observing a large number of cases of eruptions following vaccination, but has never seen one so typically syphilitic in appearance as this. On the other hand, it must be remembered that there have been as yet no general secondary symptoms, and that the first local sores were not proved to be of a syphilitic character. When first examined, after the vaccine disturbance had passed away, the local eruption was that of secondary tubercular syphilis. The interesting question then arises, whether the external efflorescence of the syphilitic virus introduced into the body in vaccination may not sometimes be limited to the exact area to which the local action of the vaccine matter itself is limited. And is it not possible that, since experiments have shown that secondary syphilis can be transmitted by inoculation without the production of primary phenomena, the primary sores do not necessarily follow the introduction of syphilis by vaccination? It is consistent with what we know of the transmission of the disease, to expect that inoculation from a vaccinifer in the later stages of congenital syphilis—a condition in which the existence of the disease is easily overlooked—would produce different results from those set up by matter taken during the primary efflorescence. In the present instance there could, Dr. Cheadle believes, be no reasonable suspicion of previously existing syphilitic taint. The character and position of the patient, whom he had known for several years, render this in the highest degree improbable. If the eruption were specific, the poison was introduced by vaccination. The vaccinifer cannot be traced. The lymph used had been preserved upon points, and the individual source of supply could not be ascertained. Dr. Cheadle informs us that extreme care had, however, been taken in the selection of lymph-bearers, and all points which showed the slightest blood-stain or opacity in the lymph were rejected and destroyed as unfit for use.

DR. J. CRICHTON BROWNE has issued cards for a medical *conversations*, to be held in the hall of the West Riding Asylum, Wakefield, on the evening of Friday, Oct. 13th, at eight o'clock.

THE total number of students in the University of Vienna in the winter session of 1870-71 was 4137, of whom 1653 were medical. In the summer session of 1871, there were 1460 medical students in a total of 3664.

A TELEGRAM from Constantinople, dated Saturday, says:—"Three cases of cholera were reported yesterday, but none to-day. The epidemic may be considered at an end. It has only proved fatal in one hundred and fifty cases."

THE mortality in Paris is still diminishing. The return for last week shows 764 deaths, including thirty from typhoid fever, fifty-three from bronchitis, thirty-nine from diarrhoea, being a great diminution; forty-three deaths from pneumonia were registered, thirty-four of dysentery, and four cases of infantile cholera.

#### CHARING CROSS HOSPITAL.

IN consequence of the promotion of Dr. Silver as Physician to the Hospital, a vacancy is created in the appointment of Assistant-Physician. Dr. Poore, who at present fills the post of Medical Registrar to the Hospital, will most likely be the successful candidate for the vacant appointment.

#### "THE PSYCHIC FORCE."

MR. CROOKES has continued his experiments on the psychic force; and, by the aid of improved apparatus, he has registered in further detail, and by automatic instruments, the movements of a heavy plank upon which Mr. Home and another person not named operated. Their

hands were placed in a metal cage suspended in bowls of water so fixed in contact with one end of the plank that he believes it clearly and demonstrably impossible that they could have exerted any pressure on the plank. The dynamometer nevertheless registered a pull on the distal end of the plank amounting, in some instances, to some pounds weight. It is to be regretted that Professors Stokes and Sharpey, or some other equally eminent physicists, do not consent to investigate these experiments, which they have been invited to scrutinise. Mr. Crookes complains that his papers describing them have been refused at the Royal Society, of which he is a member.

#### A NEW THEORY OF DISEASE.

THE Sanitary Committee of Wolverhampton have laid before the Town Council a detailed report on the sanitary state of that important town. It presents a dark picture indeed. There is the old sad story of filth and neglect—excrement-sodden soil, air, and water. There has been a recent considerable rise in the mortality; and one of the Council expressed a strong opinion as to the origin of this mortality, which is interesting to those who are now discussing the origin of specific diseases. Ordinary persons attributed them to the foul cesspools and middens, and the polluted soil and water, which, it had been prophesied, would produce this effect. There has been a local epidemic of small-pox; and its extension was attributed by Mr. Turton and Mr. Collins, two medical members of the Council, to the fact that there are no means of isolating the existing small-pox cases, and no fever or small-pox conveyances. It was the conviction of Councillor Willcock that it was not the nuisances themselves which caused the mortality, but the publication of the reports describing them. The mortality had doubled during the last three months, in which these reports were published, or, as he put it, "since they had stirred up the nuisances," which had "a detrimental effect upon the nervous system of nervous people." This new development of the theory of a variety of "psychic force" did not, however, we are glad to say, find favour with the majority of the Council. We are glad to see that there is reason to hope that the rulers of Wolverhampton will provide themselves with a medical officer of health, and try to save the lives of the people, without fear that their efforts to clean the cesspools and to purify the wells will injure the nerves of the most sensitive of "nervous people" or the blindest devotees of zymotic poison.

#### ROYAL COLLEGE OF SURGEONS.

THE Hunterian Museum has just received a valuable addition through the liberality of Mr. Francis Kiernan, F.R.S., a late member of the Council of the College, who has presented the whole of his museum of wet and dry preparations. This collection is especially rich in illustrations of the structure, normal and morbid, of the liver; for his discoveries in which important organ, he justly obtained the Fellowship of the Royal Society. We congratulate Mr. Kiernan and the College, the one on his wise liberality, and the other on a valuable addition to the treasures of the Hunterian Collection.

#### THE HEALTH OF LONDON.

THE deaths in London last week were 83 below the average, the total number having been 1,283. The deaths from diarrhoea have steadily declined from 487 in the week ending August 26, to 80 last week; this, however, was more than double the number referred to the disease in the corresponding week of 1870. Of the 80 cases last week, 72 were of infants under two years of age. The fatal cases of small-pox, which in the three previous weeks had been 57, 89, and 51, were last week 72, or 57 above the corrected average number in the corresponding week of the ten years 1861-70. There were 38 deaths from scarlet fever, 5 from diphtheria, 36 from whooping-cough, and 32 from different forms of fever (of which 4 were certified as typhus, 21 as enteric or typhoid, and 7 as simple continued fever). The mean temperature was 51.9 deg., or 1.4 deg. below the mean temperature of the corresponding week in fifty years.

## MEDICAL OFFICER OF HEALTH FOR ISLINGTON.

WE learn with sincere pleasure that Mr. Haviland, author of the lectures on Medical Geography, to which we have more than once called attention, has been elected Medical Officer of Health for Islington, in the room of Dr. Ballard. Mr. Haviland had worthy competitors, and either of the two gentlemen selected with himself for final competition, would have done honour to the office. But they are younger men, and opportunities will not be wanting for their just promotion, for which we sincerely trust they will not have long to wait. Mr. Haviland has not only rendered great services to public medicine; but has made great sacrifices for it. In any other country, he would have had, long before this, assistance and support in his labours from Government funds, and suitable opportunities for continuing his valuable and costly work. We must take the disadvantages of our by no means paternal form of government with its advantages, and look to local self-government to do, as far as it can, the work which a centralised government often finds more easy. It is no great prize which has fallen to Mr. Haviland—a place of much labour and responsibility and modest remuneration. But it suits the bent of his mind and his peculiar capabilities, and we congratulate him and the good people of Islington on his election as their Medical Officer of Health.

## VACCINATION PROSECUTIONS.

AT the Southwark Police-court, William Dwyer, Charles Edwards, and Richard Worrell, labourers, were summoned for neglecting to have their children vaccinated. Notices had been served on all the defendants several times, the first two years ago. A short time since, the children had small-pox, and were removed to the Small-pox Infirmary at Stockwell, cured, and restored to their homes. Worrell said he was guilty in not having had his children vaccinated; but the small-pox was brought into the house, and his wife and two other children who had been vaccinated caught it, by which he was put to considerable expense. Edwards said his child was delicate, and he was afraid it would injure her: all his other children had been vaccinated. Dwyer expressed a strong antipathy to vaccination; about nine years ago, he said, his sister had a child vaccinated, from which the arm and side festered so much that it lost the use of its side. Each defendant was fined five shillings and costs; the magistrate remarking that if they had not suffered so much from this dreadful disease, he should have imposed the full penalty.

## THE COMING SHOWER OF GOLD.

MR. GODWIN has a benevolent friend who is preparing to descend upon London in the form in which Jupiter made his way to Danaë; and the modern Danaë, we can answer, will be as anxious to embrace him as the ancient. As President of the Health Department at the Social Science Congress, in his address this week, he said: "I have for some time been authorised by an inhabitant of London to state that he is willing and ready to appropriate to the improvement of the health and condition of the poorer classes of the metropolis a sum equal to that given by the late George Peabody for a similar purpose—or, say, half a million of money—when he can see a mode of satisfactorily effecting this without fear of pauperising the classes he seeks to benefit. Means were taken to make this offer known to a limited extent, and a large number of suggestions have been sent to the proposer; but he is not yet satisfied as to the course that can wisely be taken." This opens a wide field for the largeness of those who are cognisant of the dreadful waste of health and happiness amongst the poor. Looking to the undoubted fact that the greatest sum of human misery in modern society is due to intemperance, we could wish that some efficient means could be devised for rendering the interest of this sum available for a serviceable and effective crusade against that perennial source of degradation, disease, death, and moral ruin, among the poorer classes. We should be a happy people indeed, if we could master this growing curse, and quell this rising flood which steepens a large proportion of our millions to the neck in crime, in misery, and in the slough of physical and moral death.

He would be a happy and a never-to-be-forgotten benefactor of his race who could help us to make a great beginning in the strife. The metropolis does not suffer alone. It is impossible to read without an almost hopeless sinking of the heart, that calm, clear, pitiful, and sincere report which Drs. Parkes and Sanderson have just presented to the Town Council of Liverpool, in which they describe the irresistible mass of evidence which has led them to the conclusion, that at the bottom of the fearful excess of mortality in that wealthy and intelligent city lies this one wide-spreading curse, intemperance. The people herd together like brutes; they couch at night in flocks in miserably crowded and fetid rooms; they have neither food, furniture, nor clothing; their children are killed off in hecatombs by exposure, slow starvation, and neglect, because husbands and wives, fathers and mothers, earning regularly from twenty to twenty-seven shillings a week, and often much more, waste all their substance in drink—brutify themselves with alcohol; and sink habitually by tens of thousands into the most fatal disregard of the habits of life necessary to health, morality, and public safety.

## SALFORD HOSPITAL MEDICAL SOCIETY.

THE inaugural dinner at the close of the first year of this Society's existence took place on Thursday evening, the 28th ultimo, at the Cattle Market Hotel, under the presidency of Mr. Boutflower, the senior member of the hospital staff. About twenty-five practitioners of the borough were present, including Mr. Stocks, the Honorary Secretary of the Society, to whose indefatigable exertions the Society mainly owes its formation. The usual toasts were felicitously proposed and responded to by Mr. Boutflower, the Vice-President, Mr. Somers, Mr. Stocks, Mr. Hall, and others. Some vocal and instrumental music by the more harmoniously gifted members contributed much to the enjoyment of a very pleasant and desirable *réunion*.

## THE LEGALITY OF NECROPSIES.

THE authorities of Guy's Hospital have again been summoned before the magistrates, accused of having opened a body without the permission of the friends of the deceased. It may be remembered that, to obviate the constant recurrence of such complaints as that now before the public, a rule was made by the Committee at the Hospital to the effect that they reserved to themselves the right of making *post mortem* examinations when deemed necessary. If the case were not likely to afford any very valuable pathological information, and the friends were much opposed to the examination, it was provided that a necropsy would not be insisted upon. This rule was printed and suspended in the admission-room, for the information of patients and their friends. We repeat that it seems to us an eminently just and judicious rule. Humanity and science are alike interested in the proper scrutiny of the conditions of hidden organs of those who have died of disease. It is a proper rule that patients dying in public institutions should render this last service to the humanity which has succoured them. Nothing but an unworthy and ignorant prejudice opposes it.

## ST. GEORGE'S HOSPITAL: TESTIMONIAL TO DR. THOMAS JONES.

DR. THOMAS JONES, who has for several years discharged in a very able and acceptable manner the duties of Resident Medical Officer to St. George's Hospital, has, on commencing private practice in London, received very gratifying testimony to his worth and popularity in the shape of a valuable timepiece from the nurses, and a gold watch from friends and students of the hospital. The latter was accompanied by a note from the Rev. Mr. Rooke, the Chairman of the Committee, on behalf of the subscribers, requesting his acceptance of the gift as a mark of their esteem and regard, and of the appreciation by those of them who had been students in the hospital of Dr. Jones's uniform kindness and the advantages they had derived from his instructions in the wards. A warm expression was also conveyed of their hearty good wishes for his success in the professional career on which he has just entered.

## OVIARTOMY IN MANCHESTER.

OUR Manchester correspondent informs us that in 1870 there were two cases of ovariectomy performed at the Royal Infirmary of the city, both cases proving fatal; and that this year there have also been two cases, each patient making a rapid recovery—Mr. Southam's last case, indeed, leaving the hospital within five weeks of the operation. In this case Macleod's clamp was used, and one catgut-ligature. At St. Mary's Hospital, there was in 1870 not a single case of ovariectomy; this year Dr. Lloyd Roberts has already operated five times with an uniformly successful result. He attributes his success to the fact that he has in every case succeeded in extracting the tumour through a small incision, varying from two to five inches, and to the antiseptic plan of dressing which he has adopted. Though the external wound has been so small, the tumours in some cases have been very large and heavy, varying in weight from 19½ lbs. to 43 lbs.

## COTTON-WOOL RESPIRATORS.

ONE or two of the medical men in the neighbourhood of Manchester have adopted the plan of wearing a cotton-wool respirator during their visits in cases of contagious disease—the respirator being applied on entering, and removed on leaving, the house. As, however, the nostrils are still only guarded by the natural filter afforded by the *vibrissæ*, it is doubtful whether this will prove an effectual barrier to the entrance of the poison. It does not seem unlikely, nevertheless, that the practice will become general should cholera assume serious proportions. It must be always remembered that, even though the respirator may afford some protection to its wearer, its use will not obviate the necessity of care on his part against becoming a means of conveying contagious disease.

## ASSOCIATION OF GERMAN NATURALISTS AND PHYSICIANS.

THE forty-fourth annual meeting of this Society has lately been held in Rostock. It has entered on the fiftieth year of its existence, having been founded in 1822 by Oken, who brought together twenty-one naturalists in Leipzig. Since that time, a meeting has been held each year, with five exceptions. In 1831 and 1832, the meetings were suspended on account of the prevalence of cholera; in 1848, on account of political disturbances; and in 1867 and 1870, on account of war. The recent meeting was not so numerously attended as usual, many of the members having been probably detained at their homes through a fear of their professional services being required on account of the occurrence of cholera. One of the principal features of the meeting was an eloquent address by Professor Virchow, on the position and prospects of natural science in the new national life of Germany.

## THE ITALIAN MEDICAL ASSOCIATION.

THE programme of the meeting of the Italian Medical Association, now being held in Rome, contains notice of discussions on several interesting topics. The first meeting was to be held on the 15th for the transaction of some preliminary business, among which was the nomination of a committee to visit the sanitary institutions of the city. Among the subjects to be discussed on subsequent days, is that of the reorganisation of medical education in Italy. Discussion is to take place on the questions, *inter alia*, whether general (secondary) education should be uniform in all cases, or should be modified for those who are about to enter the medical profession, and if so, how it should be modified; whether professional study should be uniform in all the higher medical schools of the kingdom, or whether any reasons exist for allowing special exceptions; and how far freedom of medical teaching may be useful in Italy. Reports will be presented, and discussions raised, on the following subjects: The surveillance of prostitution, and the means of preventing the spread of syphilis (this discussion will be held *in secret sitting*); on the noxious influence of rice-fields both on the surrounding population and on the inhabitants of places at a distance, exposed to winds blowing in a direction from the fields; on the advisability of adopting a tariff of fees for medical and surgical attend-

ance, consultations, and operations, and of submitting such tariff to the approval of the government. The Executive Committee will take the sense of the meeting on the subject of the publication of an ethical code; and, if the proposal be approved, a professional and moral code will in the course of the next six months be drawn up and presented for the approval of the several committees, as the expression of opinion of the medical profession. The Committee will also, on the suggestion of Dr. Bargiotti, submit the following proposals: 1. That a course of instruction in practical hygiene should be given in every technical school in Italy, with the object of pointing out the means of preserving operatives from the dangers inherent to various branches of industry and manufacture, and of stimulating them to devise means of obviating these dangers; 2. That the masters and mistresses of elementary schools, as being by law pupils of the normal schools, should be required to attend every year, for a period of time to be determined, a course of private hygiene delivered by medical men, so that they may have the necessary knowledge to enable them to impart the instruction to the pupils entrusted to them—for instance, by means of copy-slips containing easy and comprehensive maxims of practical hygiene.

## THE CONTAGIOUS DISEASES ACTS.

THE question of the Contagious Diseases Acts was discussed this week at a meeting of members and associates of the Social Science Congress, Mr. H. N. Mosley, Professor Amos, Mr. Littleton of Devonport, the Rev. Dr. Rigg, the Rev. Dr. Hooppell, Mr. Mundella, and Mrs. Butler, spoke in favour of the repeal of the statutes; and Mr. J. Armstrong, Mr. G. W. Hastings, Mr. Alsager Hill, and Dr. Waddilove, advocated their continuance. Finally, a resolution was carried to the effect that the Council be requested to urge upon Government the desirability of repealing the Acts, and of amending the laws relating to offences against women. During the proceedings, a gentleman drew the attention of the chairman to the fact that a number of ladies were present. The chairman said that it was intended that ladies should be there. The gentleman then said that, as the ladies would not go, he should; and, "amidst laughter and shrill hisses," he retired.—The annual meeting for the repeal of the Contagious Disease Acts was held at Leeds on Saturday afternoon. Mr. Mundella, M.P., who was one of the Royal Commissioners on the Acts, contradicted the statement made by the Home Secretary in a late speech in respect to the change brought about by the working of the Acts in Devonport. Mr. Bruce had, he said, evidently confused the information that had been forwarded to him, for he (Mr. Mundella) was sure that Mr. Bruce was the last man who would wilfully make a misstatement. Mr. Mundella expressed a firm conviction that the repeal of the Acts would soon be accomplished. Mrs. Josephine Butler and others addressed the meeting, and resolutions in accordance with the principles of the society were adopted.

## THE HAMPSTEAD HOSPITAL.

THE Hampstead Small-pox Hospital inquiry is apparently likely to last for at least another week—perhaps another fortnight. The case for the complaining medical officers is finished, and that for the managers is opened. We abstain from expressing any opinion whatever upon the case as presented. But, whether the charges brought have been justified or not upon the showing of those who brought them, we cannot but regret that the circumstances have involved these three young men in a heavy expenditure. They now declare themselves to have already expended four hundred pounds on the lawyers whom they have employed, and to be unable to bear the expense of further legal advice in cross-examining the witnesses of the managers. It will be very important to the interests of justice, and for the satisfaction of the public mind, that they should have this assistance. We see with pleasure that the managers have petitioned the Poor-law Board to allow their accusers legal assistance; and we think this is a case in which the public will not grudge the expense. If the Poor-law Board feel unable to pay the expenses of those who are attacking the administration of the Hampstead Hospital, we trust that the public will subscribe

enough for the purpose. If the final verdict be adverse to Messrs. Aikman, Greaves, and Kynaston, the moral obloquy which will attach to their conduct will be hard enough to bear; and in any case it would be regrettable that they should have to suffer in pocket.

#### REGISTRATION OF STUDENTS.

THE result of the registration of students pursuing their professional studies at the metropolitan medical schools will not be brought to a close at the College of Surgeons until Monday next. At the hour of going to press, we have ascertained that the numbers of new entries already registered are as follows:—Guy's, 78; St. Bartholomew's, 77; University College, 59; St. Thomas's, 48; King's College, 35; London, 23; St. Mary's, 20; Middlesex, 10; Westminster, 9; St. George's, 8; and the Charing Cross, 8. The total number registered up to Thursday evening was 1,039. The actual numbers of new entries at the various schools as returned to us by the respective officials of the schools up to Thursday morning are as follows:—St. Bartholomew's, present year's entries, 88. University, new entries, 81. St. Thomas's, first year, 54; total new entries, 78. Guy's, total entries, 77. King's College, first year's students, 40; St. George's, new students, 26, including 5 from Cambridge University. St. Mary's, number of entries, 23. Middlesex, first year, 14; total new entries, 18. Westminster, fresh entries, 13. Charing Cross, first year's men, 11.—The entries at the provincial schools are:—Manchester, new, 32. Liverpool, first year's men, 23. Bristol, first year's men, 17.

#### THE THERMOMETER IN GUNSHOT INJURIES.

AT a recent meeting of the Academy of Sciences in Paris, M. Demarquay stated that he had found that wounds from fragments of shells or from bullets, during the last siege of Paris, were attended with the greatest amount of lowering of temperature in persons who were, when wounded, in a state of intoxication, and who had long been of intemperate habits. In all cases where the temperature fell below 95 deg. Fahr., the patients died, whether operated on or not: if an operation were performed, there was no reaction. In six cases of penetrating wound of the abdomen, the temperature fell rapidly to 95 deg. and even to 93.2 Fahr. He also called attention to the fact which had already been pointed out by Billroth, that severe and slightly extensive burns are most frequently attended with a considerable lowering of the temperature of the body. It is M. Demarquay's intention to prosecute further researches on the causes of lowered temperature in certain conditions of disease.

### • SCOTLAND.

#### CRAIG *versus* JEX-BLAKE.

MISS JEX-BLAKE was on Monday presented with a cheque for the sum of £1030 12, the amount of the Jex-Blake Fund subscribed to defray the costs of the action brought against her by the student Craig. The presentation took place at a public meeting in the Council Chambers, Edinburgh, the Lord Provost in the chair. The honorary Treasurer, Miss Louisa Stevenson, stated that, after all expenses had been paid off, a surplus of £112 19 remained. As the subscription list had been closed in August, she had been obliged to return a large number of names sent to her since. In thanking the subscribers, Miss Jex-Blake in the course of her remarks, and after referring in some detail to the action brought against her, said, "I hear that some of our opponents have been boasting that they have heard the last of the lady students; that our cause is now hopelessly lost. I am no prophet; but I think I might venture with some confidence to predict that never has our cause been so nearly won; that almost certainly before twelve months have passed over our heads, we shall, thanks to this same British love of fairplay, this constant sympathy which never fails the weaker side when its cause is a just one, have obtained even in this very university everything that we need and desire." The surplus sum which had been handed to her Miss Jex-Blake proposed to add to the fund for the purpose of founding a future hospital for women in Edinburgh.

## THE MEDICAL INSTITUTIONS AND PREVAILING DISEASES OF VICTORIA.

[FROM A SPECIAL CORRESPONDENT.]

AFTER having spent a few months at the Antipodes, I think it may not be uninteresting to many of the readers of this JOURNAL if I describe some of the medical institutions of the colony of Victoria, which in wealth and population is by far the most important appanage of the British crown lying entirely in the southern hemisphere. To many the name Victoria conveys little more than a hazy notion of gold-fields and sheep-runs; and to eight out of ten of the inhabitants of our island the information that Melbourne is quite as large a city as Edinburgh will come as a new and striking fact. With the political, commercial, or social aspects of Victoria I am, however, in no way concerned, except in so far as they bear at the present moment on the condition and status of the medical profession in it, on the extent and efficiency of the public and private institutions for the medical relief of the sick or insane, and on the prevailing diseases.

MELBOURNE HOSPITAL.—Among the various institutions for the alleviation of the sufferings of the sick poor, none occupies a more honourable and important position than the Melbourne Hospital, founded in 1848. The great flood of immigrants in the first days of the gold fever crowded its small wards with hundreds of the worst possible surgical cases: and, as I was informed by some of the oldest surgeons, a very large proportion of those cases did badly, and no one who bears in mind the peculiar circumstances of those days can wonder at it. Men were then living in a constant condition of extreme nerve-tension, fighting and struggling for gold as for their very existence, with bad and deficient food, many of them literally living upon alcohol, or rather upon poison diluted with water, and exposed under canvas to every vicissitude of weather; so careless did they become even of their own lives that they would take no precautions, and the result became inevitably that which the Melbourne surgeons were compelled frequently to witness after even the most trivial operations.

There unfortunately are no accurate statistics of this period of the hospital's existence, and it is only upon the general impressions of the surgeons who had the greatest experience of that strange time that I rely; but how suddenly the resources of the hospital were strained to the utmost extent may be readily recognised by a glance at the total number of in- and out-patients relieved in the year of the foundation—1848—as compared with those of the first years of the gold-rush, 1853 and 1854, when the numbers were 187 in the first, and 1,748 and 3,164 in the two latter respectively. The hospital is now enormously increased in size, as may be easily seen from the records of the year 1870, which show that the number of patients relieved had then reached on an aggregate nearly 25,000. The building is, however, often necessarily overcrowded, over four hundred beds having been occupied at one time, while the cubic capacity is barely sufficient for more than two hundred and fifty.

It is a large red brick edifice, standing very centrally, and at no great distance from Bourke Street, one of the principal thoroughfares of the city; but unfortunately it has not sufficient vacant space about it—space which at the time the hospital was built was scarcely of any value, but now could not be had except for enormous sums. The older part of the hospital, having been built in 1848, is naturally on the corridor system, the central block having a couple of wings at right angles to it. The lower storey of this central part is purely administrative—offices, apartments for resident officers, etc.; but there are a couple of storeys above which are separated into two long and narrow wards by the corridor. The windows are small and open at the top, the frame of this portion being so adjusted as to direct the current of air upwards. On the opposite wall we find a fireplace, two doors, and several small windows, so that there is as good cross-ventilation as can be had on the corridor system. These wards were overcrowded, there being twenty-two beds in each, but they were very clean, the floor being waxed and the walls oil-painted, and rendered cheerful by some lithographs and prints. The present operating theatre is a small room cut out of one of these central wards, and neither spacious nor well lighted; but the plan of a new one has, I understand, been already approved of by the building committee. The west wing, at right angles to this central pile, has lately been greatly improved by the removal of the corridor between the wards, which have thus been thrown into one wide room, and by the closets and baths having been erected exterior to the wards, instead

of in them as previously. The ward is thus free on three sides, and is, in consequence, both more airy and better lighted; but four rows of beds (ten in each row) cannot be considered a desirable arrangement if possible to avoid it; and besides, in the erection of the closets and baths no attempt has been made to introduce a cross-ventilated passage between them and the ward door, so that virtually they may still be said to be in direct connection with the ward. Into the eastern wing the same improvements have not been introduced, and it is cut up into a number of small wards and rooms, one of which is used as a female lock hospital.

The finest and largest wards in the hospital are a couple of handsome two-storeyed pavilions, only recently constructed, to the east of the main building, and only connected with it by a covered passage. These wards face east and west, and the entrance and staircase are at the northern extremity. The wards themselves are very large and capacious, with opposite windows, and a great number of grated wall ventilators. The lavatory, bath-room, and closets opened off one side of the southern extremity of the ward, while at the other there was a small separate room for two patients. Nominally there are only twenty-five beds in this ward, but this number is frequently exceeded. The walls were oil-painted, the floor well waxed, and everything looked clean and neat, as was indeed everywhere the case throughout the whole building; but there was, to my mind, one great fault—the roof was made of wooden beams, varnished, it is true, but none the less capable of rapid saturation with septic germs, and fatal to the perfection of the splendid pavilion. Those four wards have only been a short time in use, and I was assured by one of the surgeons—Dr. Barker—that no cases of pyæmia or erysipelas had as yet occurred in them.

There is another completely isolated block of buildings for out-patients, the lower portions of which, besides being very well laid out for their systematic reception, contains a large dispensary. The upper storey is an ill-contrived and badly ventilated ward, containing female surgical patients and children. There is a small separate dead-house and *post mortem* room, but no special pathologist has been appointed, as each physician or surgeon is supposed to make the necropsies on his own patients; but lately, I believe, an office of Curator of a Pathological Museum has been created in connection with the University. The staff consists of five physicians, one assistant-physician, and eight surgeons.

THE ALFRED HOSPITAL, so named in commemoration of Prince Alfred's visit to Melbourne, is situated on a tract of land granted by government, off the St. Kilda Road, about two miles from the centre of the city, and not very far from the bay. The site, though airy at present, and unenclosed, cannot be called a good one, as it is only very slightly elevated above the sea-level, and, indeed, the greater part of the ground between it and Hobson's Bay is a permanent swamp. This is not of so much consequence as it might be, as the sewage of the hospital is to be received in air-tight iron tanks on Liemur's plan.

Only a small portion of the original design of the hospital has, as yet, been carried out, as the committee have not by any means the necessary funds for completing the remainder; but the part finished, consisting of a central block and one pavilion, is a handsome red brick structure, in the Elizabethan style, so much affected now-a-days in our public buildings.

On entering the central block, one finds on the staircase to the upper storey a large and gaudily stained glass window, execrable in taste, and very badly finished. The lower storey is principally administrative; but the out-patient department, patients' waiting-rooms, accident-room, and dispensary, are also contained in it. Above, besides rooms for the matron, dispenser, etc., there is one fine ward at each end of the corridor, and at right angles to it. These, being partly pavilion wards, are roomy and well-lighted. They measure 60 feet by 18; and all the rooms in the building are 16 feet high, so that those which are only intended for nine patients give nearly two thousand cubic feet to each.

To the right of the central building, and connected with it by an open passage, is one of the most admirable pavilion wards in two storeys I have ever seen. On entering at the northern extremity, there are first a number of small rooms, intended as operating theatre, nurse's-room, etc.; then one large ward, 125 feet long by 24 ft. 9 in. broad, and 16 feet high, which is beautifully lighted by eleven windows (11 feet by 4 feet) on each side, and well ventilated besides by roof- and wall-ventilators, so numerous as to afford 162 square inches of opening to each bed, even after the deduction of the grated iron work covering them. They are immediately above and below each window, and the air is directed, by a valve in the lower series, obliquely downwards, while, by an equally simple arrangement, the upper set have their valves opening towards the ceiling. Exactly facing the entrance-door, there is, at the other end of the ward, an open verandah, into

which the patients can enter from the ward, while at each side of the verandah-door there is a single window. The bath-room and lavatory open off one side at this extremity of the ward, while the closets (on Liemur's patent) open off the other, and both are separated from the entrance-door into the ward by a small passage, with cross-ventilation. As those wards are intended for only twenty-two patients, one bed being between two windows, there are more than 2000 cubic feet of air to each patient, and the constant renewal of the air seems amply provided for. The walls are covered by a kind of cement, and the floor is highly varnished.

This pavilion, which has two storeys, is, as yet, the only one which funds have permitted the committee to erect; but they trust soon to be in a condition to go on with other three exactly similar. Even with only the forty-four beds now ready, and at the disposal of the recently elected medical and surgical staff, such an opportunity is rarely offered for the fair trial, in surgical cases, of pavilion wards, with ample cubic space, excellent ventilation, and a constant supply of air nearly uncontaminated by the impurities of larger home cities;\* and the officers will be greatly to blame if they follow the bad example set by the larger Melbourne Hospital, in neglecting to enforce the utmost care in the due registration of all their cases.

THE BENEVOLENT ASYLUM, which takes the place of the London workhouse, is a very large building on an eminently good site; but when I say that it is very dirty, wretchedly arranged, and frightfully overcrowded, I am using but mild expressions for its present condition; and it may perhaps afford some consolation to the guardians of the St. Pancras Workhouse to know that there is a sister institution at the Antipodes which just as often appears as the object of attack and invective on the part of the Melbourne newspapers, and apparently with as much justice, as their own far-famed institution used to do in the columns of the London papers.

THE LYING-IN HOSPITAL, close to the Medical School, is now twelve years old, and the present physicians to it are naturally proud of the very fair statistics they have been able to publish. It must be recollected, however, that with such a new building the statistics are not of so great consequence, as almost every such building is likely to give good results at first; and it is certainly very far from being a model maternity to my mind, being built on the corridor system, with a number of small rooms, to contain four or five patients in each, opening off the passage. This is the main part of the hospital; but from each end of it, and running along two sides of a small garden-plot, there is a block of low wooden buildings, subdivided into small huts, eight of which on one side are used for lying-in rooms. These rooms, which are both low in the ceiling and diminutive in every respect, open off a narrow verandah nearly on a level with the garden-soil. The light is admitted into them through small windows in the wall opening into the verandah; and the cross ventilation is provided for by a tiny aperture—it cannot be called a window—high up on the opposite wall. In each room there are two iron bedsteads, the patient being shifted from the lying-in couch to the other immediately after delivery; while the general puerperal ward is in the lower storey of the central block. The Medical Report for 1870 mentions that the total number of accouchements in the midwifery wards up to the end of that year had been 4,183, and the mortality 53, or 1 in 80.4; while in the year ending December 31st, 1870, there were 401 deliveries, and 5 deaths, being 1 in 80, or as nearly as possible the average mortality.

THE MEDICAL SCHOOL, not far from the Lying-in Hospital, is a separate pile of buildings, in the shape of a quadrangle, lying within the University enclosure. An admirable dissecting-room, both well lighted and well ventilated, is one of its best features; and the lecture-rooms, too, seem perfectly suited for their purposes. Under the same roof there are a chemical laboratory; collections of chemical, botanical, and therapeutical specimens; a students' reading-room, with a fair show of the most recent medical works and the best periodicals; and an anatomical museum. In the latter there is a curious skeleton of a Frenchman who used many years ago to be well known in Paris, where he was in the habit of sitting at the gate of Notre-Dame playing on the flute. Besides being a deformed dwarf, this man had the ordinary number of thigh-bones; but the two united to form only one knee-joint, with a single tibia and fibula; and to the latter there was articulated only one foot. When the present Professor of Anatomy—Professor Halford—joined the University, some eight years ago, there were only two medical students, while there are now upwards of thirty. The curriculum for the degree of M.D. entails five years' study, and there are tolerably severe examinations at matriculation and in the dif-

\* Wood, it must be recollected, is very much used in Melbourne as fuel. Besides, the site of the hospital may be said to be suburban.

ferent subjects at the end of each year. Nearly all the branches of medical science, in fact, are taught; and there is ample opportunity for the study of natural history under Professor McCoy, and of botany also, the Botanical Gardens under Dr. von Mueller being admirably adapted for the student who desires to know something of the plant-life of the southern hemisphere. It is a remarkable fact, however, and one that does not speak well for the generosity or enterprise of the surgeons and physicians to the Melbourne Hospital, that, although willing to allow the students to accompany them in their visits to the wards, they one and all of them quite recently refused point-blank to give any clinical lectures, so that the students are utterly deprived of what at the present day is considered by far the most important part of a practical medical education.

[To be continued.]

## ABSTRACTS OF INTRODUCTORY ADDRESSES

DELIVERED AT

### THE PROVINCIAL SCHOOLS,

On OCTOBER 2nd and 3rd, 1871.

#### MANCHESTER ROYAL SCHOOL OF MEDICINE.

THE Introductory Address was delivered on October 2nd, by Mr. R. T. HUNT, Lecturer on the Physiology and Pathology of the Eye, and consisted of an exposition of the lecturer's views on medical education, which were, he said, in some respects, different from those generally entertained.

Speaking of lectures, he said that their utility had been acknowledged from the earliest times of civilisation; and, as attendance upon them was required by all the examining bodies, it became the duty of every student not merely to be regular in attendance upon them, but also to reap all the benefit which might accrue from this mode of tuition. By directing the mind to a fixed subject at a fixed hour the valuable habit of concentration of thought was much strengthened—a habit which would be found of the highest importance in the future practice of the profession. Attendance upon lectures at a fixed time was a great check, if not a complete remedy, for the disposition to procrastinate. The answer to the question whether it was useful or not to take notes of a lecture would require modification, according to the nature of the lecture. When a lecture consisted in demonstration of the structures of the body, or of models or drawings, taking notes would materially interfere with that attention which ought to be given to the descriptions. The same remark would apply to lectures on chemistry, materia medica, and botany, but not to the same extent. In all these instances very short notes were quite sufficient. But a careful taking of notes of lectures on medicine, surgery, pathology, and forensic medicine, provided the notes were not too copious, would much facilitate private study. The limited number of lectures upon each of these subjects required a condensation and arrangement by the lecturer, which would be an excellent guide to the student in directing him in his reading. The student should as much as possible confine his attention to the elementary branches until these were thoroughly mastered; and this would be the only good preparation for afterwards acquiring a knowledge of the more complicated branches of medical study. The student's reading should be confined chiefly to those subjects which have engaged his attention at lectures during the day; but evening studies should be restricted to the revision of notes. After the mind had been engaged all day in acquiring knowledge, it was not in so good a state for steady and serious reading as after the refreshing sleep of the night. The ideas then were clear, the judgment sound, and by an hour or two of real study, not mere reading, the mind was admirably prepared for the labours of the ensuing day. On the contrary, night study could only be carried on by a degree of excitement which, if long continued, impaired the mental powers and was highly prejudicial to the general health. The examples of the advantages of early morning study to men of science were numerous; as examples, the lecturer mentioned John Hunter and Sir Walter Scott. It is probable that the medical students of Manchester would in future possess the advantages of university education by means of Owens College. The lecturer was of opinion that instruction in classics, mathematics, or other departments of science should be given previously to the commencement of medical studies. He feared that the attention of students of the present day was too much devoted to minute or microscopic anatomy, before having thoroughly acquired a know-

ledge of elementary anatomy. He did not at all wish to discountenance minute anatomy, but during the course of medical study it was much more material thoroughly to acquire the elementary knowledge before the student attempted microscopic examinations, except under the direction of his teacher. He can rely upon these until the advance of medical science clears up many difficulties connected with minute anatomy. In physiology much remained still unsatisfactory. There being both true and false theories, it should be the business of every student, before accepting any theory, to see what there was to support it and what was said about it by those better able to judge of its correctness. Sir Isaac Newton no doubt greatly advanced the science of optics; indeed, almost all the rules of what might be called mathematical optics had only been the more distinctly proved correct by the lapse of time. But he supposed light to be a material body that passed through transparent substances; whereas the vibratory or undulatory theory is now proved to be the true one. If, therefore, a man of the transcendent talents of Sir Isaac Newton gave rise to a mistaken theory, scientific students should be very guarded in receiving any theory not yet properly confirmed by experience. Among what he might call modern fanciful theories was that ridiculous one of Darwin in regard to the origin of species and of Huxley regarding vitality. Because these theories might be wrong, that was no reason why we should rashly conclude that other theories were not right; but it should at all events be remembered that the only truly useful theory was that which was not made for facts but was founded on them. While appreciating in their work the value of such mechanical assistances as the microscope, stethoscope, and ophthalmoscope, the students must not place too much reliance upon these aids, to the neglect of their own natural means of acquiring information by observation in the science of anatomy, in *post mortem* examinations, etc. With regard to the moral and general conduct of medical students, he would only offer his assent to the general views, and say that his firm conviction was that no man who was not a good member of society could be an useful and honourable member of our profession.

#### QUEEN'S HOSPITAL, BIRMINGHAM.

THE following is an abstract of an introductory lecture to the clinical course, delivered by Mr. FURNEAUX JORDAN, Surgeon to the Hospital.

The lecturer congratulated his pupils on entering the medical profession at a time when the vocation stands higher in public esteem than it has ever promised to do. Having insisted on the necessity of a good preliminary training—in which he assigned a high position to the study of metaphysics (*e.g.*, Sir W. Hamilton's Essays) in early manhood—he pointed out the special qualifications necessary for the study of disease. A complete knowledge of anatomy, physiology, and human chemistry, was stated to be the true foundation on which to build a knowledge of disease. This basic knowledge having been obtained, the student proceeds to learn his "highest, and best, and life-long lesson, the truths of disease." In a hospital, the lecturer said, the student will find practical illustrations of every mode in which physiology can go wrong; and will see that work done, in the way of the investigation of the causes of disease, their pathology, diagnosis, and treatment, which they will themselves have to do in after-life. And not only this, but, if able and willing to learn, they will be taught to do all that they see others do.

"And now comes the most important question that can be asked to-day. How are you best to be taught, and how are you best to learn all about disease—to learn, in short, the science of medicine? My reply is, in the same way in which you would best be taught and best learn any science, or art, or calling, or trade, or language, or anything which men can be taught, and which they can learn. I shall be glad if I have excited your curiosity to ask what is the best way? I will answer by giving you in three words the opinion of, as I believe, the highest living authority on such a subject; the opinion, namely, of Mr. Stuart Mill. In learning anything, three things, he observes, are necessary—models, rules, and practice. The most difficult callings are best learnt as a child learns its mother tongue. It imitates such models as are near it, then it is taught rules, then it puts them into practice. If it be given the best models, taught the best rules, and afforded sufficient opportunities for practice, it best learns the language. The most successful clinical instruction, then, I venture with confidence to affirm, is that which supplies the best examples of how diseases are investigated, discriminated and treated, which teaches the best and truest rules for the observation, detection, and treatment of disease, and which affords the fullest opportunities of imitating the examples, and applying the rules. It is the appropriate combination of these methods of study which leads to success. Both teachers and learners frequently adopt one method to the exclusion of all others. One teacher, if he can be

called a teacher, for instance, will set an example only of what has to be done, and neglect to instil rules, or give opportunities for practice. Another teacher is indifferent to the importance of models, but will supply rules, perhaps to an indefinite extent, in the shape of formal lectures, in a room in which there is not a single illustration of disease. Another will set examples and teach rules, but will not encourage the pupil to imitate the examples, or apply the rules. I am compelled to say that pupils still more frequently fall into similar errors. A certain number are quite willing to witness the models, medical or surgical, and sometimes even to imitate them, but they shrink from the labour of learning the rules. These are the so-called practical men. Others see only the importance of the rules, and labour under the delusion that copious notes of systematic lectures and industrious reading by their own firesides will take the place of the imitation of models and of the practical examination of cases of disease. These are the so-called book-men. Incredible as it may seem, a few will neither witness the examples, nor learn the rules or principles, but will actually in their own sweet way examine and treat cases. It is difficult to say other of these men than that they are vain and ignorant. It is our duty as teachers to set the example of how facts are ascertained. Every method we adopt is the application of some fact, or rule, or principle; and it is our duty to explain these to you. We have, or ought to have, a reason for everything we do; the reasons are the rules.

"The perfection of clinical teaching is this: that the teacher shall set the best example and the pupil shall follow it; that the teacher shall instil the best rules and suggest the best books, and the pupil shall diligently learn them; that the teacher shall freely furnish, and the pupil freely embrace practical exercises, on the imitation of examples and the applications of rules."

Mr. Jordan then went on to inquire what are the respective peculiarities of a good teacher and of a good pupil. Good pupils, he said, develop good teachers almost as much as good teachers develop good pupils. "A teacher must be full of information; he must be accurate; he must be ready in putting his ideas into words; his mind must be clear and direct; his language must be terse and to the point; he must love his work. . . . He must frequently point to the line which divides the known from the unknown." But here the teacher (and the advanced pupil) is often placed in the difficult position of having to decide what is known and what is unknown; and, in examining new views, it is necessary to be neither too deferential to authority, nor too independent; neither too credulous nor too sceptical. The clinical teacher must make his own model of investigation, and teach the rules which have guided his actions. The teaching of rules may be difficult. "But the rules which enable the beginner to study and treat diseases are nothing more than the facts of those diseases. When the teacher elicits the facts of a disease, he is teaching and applying the rules by which the disease may be recognised. One great art in clinical teaching the rules or facts of disease is to classify them according to their importance." The lecturer pointed out that different modes of clinical teaching might be advantageously combined, and that the teacher should from time to time suit himself to the various mental characters of his pupils. The value of examinations—in which the teacher should sometimes take the place of the pupil—was also referred to.

The clinical learner should be well prepared with preliminary knowledge, and should be capable of investigation and correct inference. "A pupil should not let his teacher look at, or touch, or say, or do anything without asking the reason why, without eliciting the principle which guides the look, or touch, or question; a teacher often fails to do all the good he might by insensibly assuming that that which is extremely familiar to himself is known to others. If the pupil be critical, when his criticism is founded on knowledge, all the better. A body of advanced, informed, critical, students give rise to benefits which are not confined to themselves, they reach teachers, hospital authorities, and the poor. With such a body, there can be no indolence, no slovenliness, no inhumanity."

In the course of some further remarks the lecturer said:—

"To get knowledge, however, is not enough. It is well to cultivate every nerve-function through which knowledge may be obtained. I may say more, by way of parenthesis, that we err in unduly cultivating the ideational aspect of our nervous system. Because in pigs sensations predominate over ideas, we must not, therefore, grow ashamed of our sensations. There is at present a tendency to underrate animals, and to make ourselves as unlike them as possible. Man, however, was not intended to become a helpless bundle of ideas; although the paragon of animals, man is nevertheless an animal. Acuteness of touch, of the muscular sense, of sight and hearing, quick action, endurance, courage, are all necessary to give ideas their fullest value. Trained sight for the use of the microscope, ophthalmoscope, and laryngoscope; trained hearing for the stethoscope; trained touch for the detection of fluctua-

tion, elasticity, doughiness, crepitation and crepitus, are necessary adjuncts to trained observation and trained reasoning power. I have a strong impression that high nerve-functions run together. Often in the same man are combined the most delicate touch, the truest eyesight, the keenest emotions, the clearest ideas, the strongest will, the promptest action."

Mr. Jordan then gave some good advice, as the recording of cases, the advantage of conciseness, and the necessity of work. Speaking of knowledge and experience, the lecturer said:—

"Knowledge must be pertinent to our purpose. In the history of medicine there is no pleasanter fact to contemplate than this. When medical men have specially pursued sciences which only indirectly bear on clinical work, they have shaken off the responsibility of treating the sick. Men have been too magnanimous to grasp in one hand human life and high classics, or human life and botany, or human life and zoology, or human life and theology, or human life and active politics. Recreation and general culture are not unimportant. A rested and a cultivated mind will best pursue any profession. But if recreation and general culture rise to the first place, medical science and human life will go down to the second."

"Experience has constantly been used to imply something more than knowledge. It may be described in a medical sense as something more than a keen personal knowledge. It is not a simple act of intelligence. Experience is knowledge intensified by feeling, emotion, life. An idea will pass away; an idea associated with emotion will remain. Disease which has been personally observed, personally pondered, personally treated, is the most vivid clinical experience. To get this kind of experience should be your constant aim. To be of value, clinical experience must be personal, intense, and thorough. To examine a large number of cases superficially and hurriedly is not experience, but a spurious and dangerous imitation of it. There is unquestionably a difference between bedside experience and book-knowledge, but I think a little too much stress has been laid upon it. To a thinking man book-knowledge is experience. The written statements of competent observers give results similar to those derived from bedside observation. An active imagination is closely allied to observation, and by it the phenomena of disease, even when described by others, may be made to take a living and a breathing form. When a Watson describes the attack and the progress of an apoplexy, is it not experience? When a Paget pictures the growth and features of a cancer, is it not experience? When a Syme tells how he directly cut into an aneurism, filled the wound with his hand, quickly, yet deliberately, put his finger on the rushing orifice, and completed one of the greatest of modern operations, is it not experience? When you are reading or listening to portraits of disease, picture to yourselves the countenance, the figure, the posture, and the movements which are associated with it. Put the facts into a bed, and put yourselves at the bedside."

## SPECIAL CORRESPONDENCE.

### VIENNA.

OUR Vienna Correspondent writes to us this week as follows.

Very little has been doing at Vienna for some time, but now figures of the various nationalities of the Austrian Empire are crowding round the Krankenhaus, reading the different announcements of courses on the walls. The successor of Oppolzer is not yet appointed; but it seems pretty well decided that Bamberger is not to be the man, in spite of the recommendation of the professorial consistorium. There seems to be some political objection to Bamberger, which has favoured the supporters of another candidate. The death of Oppolzer has removed the great opponent of the therapeutical nihilism which obtains here. An elaborate physical examination, with speculations as to the pathology, histological and otherwise, and then a folding of hands with great complacency until the opportunity for corroboration by *post mortem* examination arrives, is the Austrian ideal of a physician's duty to his patient. As a school for teaching medicine as a science, the most critical could scarcely find fault; but how far medicine as an art is much furthered, may easily be questioned. It is not apparently any particular scepticism as to the efficacy of drugs, but merely a part of the scepticism prevalent here from theology to therapeutics.

In these days of inquiry into hospital accommodation as regards sanitary arrangements, ventilation, and "the hospital question," the Vienna Hospital, which is by no means a new one, holds an important position. The exterior is a hollow square of two stories, and within the enclosed space are blocks of buildings—perfect streets indeed—and in the intermediate spaces gardens, shrubberies, and leafy walks, of no

mean size. Here are to be seen patients innumerable, sitting smoking or strolling about smoking the universal pipe (the question of the effect of tobacco on German intellectual development may seriously be raised); boys engaged in gambling, and 'groups' of women gossiping; while children are pursuing games suitable to their age. The best proof of the local belief in the healthiness of their hospital is, that many authorities and teachers live within its walls—notably old Rokitansky. Within, the wards give the impression of being somewhat crowded, but are very cosy-looking, with their shaggy blankets and big stoves. There are ventilators, with indicators attached; I do not know on what principle the ventilation is conducted, but the wards are very free from hospital smell. If rigors follow us into another world, the shade of Sir James Simpson will feel very uncomfortable at many things in Vienna, and not the least at the cool way in which teachers and students pass from obstetrical operations on human forms to the obstetrical wards, after merely a good wash with soap and water. The opportunities of learning obstetrics are excellent, and to those wishful to study obstetrics and gynaecology a residence here is very desirable. The student is made to examine the patient, and to give his opinion, and his reasons for it, both regarding the nature of the case and the measures to be adopted, to the professor at the bedside. Those who wish it can easily arrange to be present at the different operations at all hours, and have opportunities of personally performing many of them. A new Pathological Institute is an additional inducement to strangers, and was yesterday visited by the ubiquitous Emperor of Brazil. Here every morning, superintending the *post mortem* examinations, is to be seen the hale and active figure of the veteran Rokitansky, whose mind is as active as his body, neither apparently impaired by either years or by honours.

## ASSOCIATION INTELLIGENCE.

### BATH AND BRISTOL BRANCH.

THE first ordinary meeting of the Session will be held at the York House, Bath, on Thursday evening, October 26th, at seven o'clock: CROSBY LEONARD, Esq., President.

R. S. FOWLER, Bath, } *Honorary Secretaries.*  
E. C. BOARD, Clifton, }  
6, Belmont, Bath, October 1871.

### CUMBERLAND AND WESTMORLAND BRANCH.

THE autumnal meeting of the above Branch will be held at the King's Arms Hotel, Wigton, on Wednesday, October 25th, at half-past twelve o'clock. The President, Dr. ELLIOT of Carlisle, will occupy the Chair.

Gentlemen intending to read papers or cases, are requested to communicate with the Secretary at their earliest convenience.

HENRY BARNES, M.D., *Honorary Secretary.*  
Carlisle, October 3rd, 1871.

### SOUTH WALES AND MONMOUTHSHIRE BRANCH: ORDINARY MEETING.

THE next Ordinary Meeting of this Branch will be held on Tuesday, November 7th, at the Town Hall, Cardiff, at 1.30 P.M. The Council will meet at 12.30 P.M.

The Dinner will take place at 5.30 P.M.; and members may introduce professional friends to the meeting and dinner.

Members intending to read papers or notes of cases are requested to communicate the titles thereof as soon as possible to one of the Honorary Secretaries.

All members who purpose joining the dinner, will oblige by communicating their intentions to one of the Honorary Secretaries before the 31st instant.

ANDREW DAVIES, } *Honorary Secretaries.*  
ALFRED SHEES, M.D., }  
October 4th, 1871.

### SHROPSHIRE SCIENTIFIC BRANCH.

THE annual meeting of the members of the above Branch will be held in the Museum, Shrewsbury, on Friday, October 27th, at 2 o'clock: Dr. J. W. MASON, in the Chair.

Several papers have been presented; and some photographs and interesting preparations will be exhibited.

Gentlemen intending to contribute, are requested to communicate with the Honorary Secretary.

The dinner will take place at the Lion Hotel at 4.30. Members intending to dine or introduce friends, are requested to send in their names not later than the 24th instant.

SAMUEL WOOD, F.R.C.S., *Honorary Secretary.*  
Shrewsbury, October 10th, 1871.

### SOUTH-EASTERN BRANCH: WEST KENT DISTRICT.

THE first meeting of the fifteenth session was held at Rochester on September 26th; J. J. D. BURNS, M.D., in the Chair.

The next meeting was appointed to be held at the General Hospital, Maidstone, on November 28th; and Dr. Davies was elected Chairman.

*Medico-Ethical Committee.*—Dr. Frederick J. Brown was unanimously elected a member of the Medico-Ethical Committee of the West Kent District, *vice* Dr. Adam Martin, deceased. The Honorary Secretary announced the withdrawal of Henry W. Joy, Esq., from the Committee. It was resolved by the meeting to fill up the vacancy at the next meeting.

*New Member.*—Dr. Alfred Wiltshire, already a member of the Association, was elected a member of the South-Eastern Branch.

*Communications.*—1. Mr. John H. Lyddon related a case of Hepatic Abscess occupying the Right Lobe, following on Dysentery, in a man that had been in hot climates. The large intestine, cæcum, and ascending colon were thickened, but not ulcerated.

2. Mr. A. W. Nankivell related a case of Traumatic Erysipelas in which 255 grains of chloral hydrate were given by mouth and rectum within six hours.—In the discussion on this paper, Mr. Hoare of Dartford related a case in which he gave 60 grains every hour for forty-eight hours.—Dr. White mentioned a case in which five grains nightly acted as an hypnotic.

3. Mr. Nankivell also read a paper on a case of Partial Luxation of the Atlas. [Mr. Nankivell's papers are published at page 437.]

4. Dr. James V. Bell read a paper on Thermometric Observations on Fever, in Relation to Prognosis. The observations were confirmatory of the following propositions. *a.* Morning temperature persistently higher than evening—almost certainly fatal. *b.* Fluctuation of temperature (accompanied by considerable range) from day to day; such as 105 down to 98 deg.; then up to 103 deg., and down again—very grave. *c.* Sudden fall of temperature in the second or third week of enteric fever betokens one of two conditions as imminent; viz., remission or intestinal hæmorrhage.

5. Dr. F. J. Brown related a case of Internal Strangulation in a man aged 66, from effusion of blood between the serous surfaces of two folds of the ileum, occurring under tormina brought on by eating old peas. Death took place in five days, with painless ileus of four days' duration. There was effusion of lymph or of serum; and the obstruction was entirely mechanical.

### WEST SOMERSET BRANCH.

THE autumnal meeting of the above Branch was held at the Railway Hotel, Taunton, on Tuesday, October 3rd, at 5 P.M. There were present W. H. AXFORD, M.B., President, and eight other members.

After dinner, the Secretary read the notice convening the meeting, which had been sent to each member of the Branch, on the 3rd of Sept., and published in the JOURNAL weekly since that date. He stated that he had not been deputed to communicate to the meeting any replies from absent members.

*Discussion on Carbolic Acid.*—The Chairman, having shortly introduced the question as settled by the Council, viz., "Does the application of carbolic acid favour the healing of wounds?" called on each gentleman in succession to speak on it. The general opinion expressed was to the effect that no healing property existed in carbolic acid; but that, on the contrary, if applied in a concentrated form, it was very irritant and destructive. From its remarkable antiseptic properties, however, when used in a diluted form (1 to 4 or 5 or oil, and 1 to 50 or 100 of water), it exercised a very salutary influence, and was a most valuable aid in the treatment of wounds. Mr. Randolph, Mr. Winterbotham, Mr. Garland, and Mr. G. Norris cited cases in support of the opinions which they gave; and Mr. Ridden exhibited the carbolic acid gauze and other of the latest improvements in the dressings employed by Mr. Lister in his plan of antiseptic treatment. Dr. Cordwain read an elaborate reply to the question, in which he stated reasons for not agreeing with the generally received theories on the subject under discussion; and lastly, the President summed up and gave his own opinion in accordance with that expressed above.

*Specimens.*—Mr. Ridden exhibited an Ovarian Cyst, which, by its

rupture, had caused sudden death. The cyst was shown to be so intimately adherent to the left side of the uterus, that if an operation for removal had been attempted during life, the uterus itself must have been removed with the cyst.

A specimen of Acute Tubercular Disease was also shown by Mr. Rigden.

A paper by the President was postponed to the next meeting.

#### SOUTH MIDLAND BRANCH: AUTUMNAL MEETING.

THE fifteenth Autumnal Meeting of this Branch was held at the Town Hall, Wellingborough, on Tuesday, October 10th; WM. W. CLARK, M.D., President, in the chair. There were also present nineteen other members, who were handsomely entertained at luncheon at the President's house previously to the meeting.

The PRESIDENT gave an address, referring more particularly to sanitary measures now mooted and being carried out, and more particularly to the utilisation of sewage.

The question was raised, as to having honorary secretaries at Bedford and Buckingham, in addition to the present two (Dr. Bryan and Mr. Moxon of Northampton), but was negative.

The PRESIDENT remarked that the medical profession ought to join the Association more freely than at present, as it has great influence in Parliament, as shown by the proceedings which have taken place there with regard to medical legislation.

*Proposed conjoined Meeting of Branches.*—It was proposed that a joint meeting of the Cambridge and Huntingdon Branch with the South Midland be held in 1871; and that the secretaries of this Branch communicate with the secretary of the Cambridge and Huntingdon Branch; and that the meeting should be the annual one of the Branches, at Peterborough, or wherever decided.

*New Member.*—Mr. George Lawrence of Towcester was proposed, and duly elected.

The question of dispensing with a dinner was raised; and it was decided that one shall take place as usual, but at the annual meeting only.

On the suggestion of Dr. Bryan, it was determined that the meetings should commence earlier than heretofore; viz., twelve to half-past, the dinner being not later than four P.M.

*Papers.*—The following papers were read.

1. The Antiseptic Treatment of Wounds; with cases. By W. Newman, M.D., Stamford. Dr. Newman, having spent most part of his fortnight's holiday this year in Mr. Lister's wards at Edinburgh, was convinced that the results outweighed all others.

2. On the Topography of Goitre. By C. E. Prior, M.D., Bedford.

## CORRESPONDENCE.

#### SMALL-POX AND VACCINATION.

SIR,—I have always maintained that Vaccination is at least as good a preventive of Small-pox as a previous attack of the disease itself. In the following instances neither has acted prophylactically.

This morning a letter-carrier presented himself to me, who has two children, aged respectively nine and five. Not only, he assures me, were they both successfully vaccinated in infancy, but both subsequently took small-pox, and are again attacked with it at the present time.

I am, etc.,  
WALLER LEWIS,  
Medical Officer in Chief.

Medical Department, General Post Office, October 9th, 1871.

#### NITRITE OF AMYL AS A REMEDY FOR CHOLERA.

SIR,—It appears to me quite reasonable and right to make a fair trial of nitrite of amyl in the collapse stage of cholera, as suggested by Dr. Talfourd Jones. I must confess, however, that I am not very hopeful as to the results of the experiment, for reasons which I will endeavour to state as briefly as possible.

Experiment proves that this agent has a remarkable power of relaxing the systemic arterioles, and so causing congestion of the subcutaneous capillaries; but I am not aware of any experiments which show that it has a like influence upon the pulmonary arterioles and capillaries. It is well known that an agent which has a powerful influence upon the systemic arteries and capillaries may have no direct effect upon the pulmonary vessels, and *vice versa*.

Then, even assuming that the nitrite of amyl has the power to relax the pulmonary arterioles in the normal state, it does not follow as a matter of course that it could exert this influence when those vessels

were abnormally contracted under the influence of the cholera poison, or that the relaxing effect, if it occurred at all, would be sufficiently durable to assist the patient's recovery. These considerations, while they render it doubtful whether the remedy in question will prove to be a physiological antidote for the cholera poison, yet rather suggest than forbid a careful trial of the drug, if such trial have not already been made.

I am, etc.,  
GEORGE JOHNSON.

Savile Row, October 1871.

#### THE WESTMINSTER HOSPITAL.

SIR,—As I find that an erroneous statement which appeared in your JOURNAL some weeks since, to the effect that the Westminster Hospital is about to be removed, is still being repeated, to the detriment of the hospital and school, you will oblige my colleagues and myself by kindly inserting this contradiction of the report.

I am, etc.,  
OCTAVIUS STURGES,  
Dean of the Westminster Hospital School.

Westminster Hospital, October 10th, 1871.

\* \* \* The statement appeared first in the daily papers. We can only regret that Dr. Sturges did not address this letter to us at an earlier date.

#### "CONTAGION" AT UNIVERSITY COLLEGE.

SIR,—Dr. Charlton Bastian's lecture on the Nature and Mode of Origin of Epidemic and Contagious Diseases marks, as you say, "an era in medical thought." It will doubtless be discussed as fully as the position of the lecturer and the power of the lecture deserve; and it is with the desire of seeking information, not of giving it, that I make these few remarks.

I conceive that Dr. Bastian's argument may be epitomised as an argument *against* the germ-theory of disease, and *in favour of*, so to speak, the catalytic nature of disease. He first of all brings arguments against the germ-theory, and afterwards other arguments in favour of the chemico-physical theory, hitherto applied to the processes of putrefaction and fermentation. His arguments against the germ-theory are four in number.

1. Dr. Bastian first argues that, as one disease where organisms are shown to exist—viz., "malignant pustule"—tends to death, so ought all diseases due to the presence and multiplication of cells tend to a fatal termination.

2. His next argument is that, as there are about twenty different zymotic diseases, therefore the germ-theory requires twenty different kinds of germs; none of which, however, have at any time been seen.

3. The third argument which he employs against the germ-theory is, that *bacteria* flourish in carbolised lotions.

4. Dr. Bastian's last argument is, he considers, his strongest. It is to the effect that, in a disease so virulently contagious as sheep-pox, the blood does not carry the disease from one animal to another, as it would be expected to do if the disease depended on the presence of living organisms.

Without attempting to fully answer these arguments, which are doubtless strong, as they are strongly reasoned, I should be glad to make one or two brief comments upon each.

1. In regard to the first, it does not appear *primâ facie* why the presence of cells other than those of the blood should tend to death, more than that they should tend to elimination. The argument would, indeed, be of precisely the same force, if it were demonstrated that in some one disease germs were eliminated, to infer that, if present, they would be eliminated in all. Further, it is by no means certain that every case of "malignant pustule" does terminate fatally. On the other hand, so far as we know, hydrophobia does invariably cause death; and yet I imagine Dr. Bastian does not see in this circumstance any evidence of the presence of germs in the blood.

2. Referring to the second argument, there is nothing more inherently improbable, so far as I can see, in the existence of twenty different living organisms of an invisible character, than there is in the existence of but one. The low forms of algae and fungi are very numerous, and yet, as a rule, breed true. Doubtless evolution has gone on here, as in the rest of the organic world; but, at the present day, persistent types exist, whether we speak of zymes or of fungi. It is no more difficult thus to conceive a cell, as yet invisible, endowed with the potentiality of typhus or scarlatina, than it is to conceive (what we know to be true) that a single sperm-cell and germ-cell contain all the morphological units of the future being.

3. That *bacteria* flourish in carbolised lotions will be new to many; and I shall look for Professor Lister's remarks on this head with great interest. In the meantime, I would observe that, far from *bacteria*

being the common cause of the different zymotic diseases, the contrary is probably true—that bacteria are never the cause of zymotic disease. The simple fact that bacteria are always and every where present, while zymotic diseases are only occasionally epidemic, would in itself render it improbable that this character of organism gave rise to contagious diseases.

4. Dr. Bastian's fourth argument is undoubtedly a very powerful one; and here again I shall await further discussion with much interest. It certainly appears to me that further evidence on this head is very much called for.

Passing to the later part of his subject, Dr. Bastian argues in favour of the catalytic character of contagious disease. But, sir, is it not legitimate to object to this, that he demands for himself exactly what he refuses to grant to others? for the establishment of his theory requires, equally with the germ-theory, the introduction of something into the blood—in the one case an organic ferment, in the other case a cell. In neither case are they demonstrated. The mind forms a distinct conception of a cell, even if it is invisible; but Dr. Bastian does not tell us what he wishes us to conceive by an organic ferment. I cannot but consider that Dr. Bastian's theory requires the existence of twenty different organic ferments, just as the germ-theory necessitates the belief in twenty different living organisms. The natural evolution of disease is certainly as comprehensible on the one theory as on the other.

I am, etc., S. MESSENGER BRADLEY.

Manchester, October 10th, 1871.

SIR,—It seems to me a matter to be regretted that Dr. Bastian should have chosen for the text of an address to neophytes about to commence their medical studies a subject much open to controversy, and concerning which many of his professional brethren, with the same evidence before them, arrive at opinions entirely opposed to his own. I beg you will allow me space for a few brief remarks on the "germ" side of the question, even though by such hardihood I should be placed, according to Dr. Bastian, on the scientific level of those who uphold homœopathy and phrenology. (*Vide Address, BRIT. MED. JOURNAL, Oct. 7th, 1871, p. 402.*)

The first objection adduced by Dr. Bastian against the germ-theory of disease is, that the maladies which depend upon the proliferation of germs within the body ought, from the very fact of such continuous proliferation, to be fatal to the host. But on this point Dr. Bastian answers himself: he concedes that malignant pustule in cattle depends upon living germs; but this disease, he says, is almost invariably fatal. The qualifying word "almost" proves the case of the other side, for it demonstrates that, in the case of a disease which depends upon the growth and multiplication of myriads of germs within the host, a condition of things may be brought about, *quoad* such host, leading to the arrest of the life of the germs, and so the arrest of the disease which they occasion.

The second objection is concerning the specificity of germs—a question which I have considered elsewhere (*The Antiseptic System*, chap. ix, p. 176), and in regard to which I will here only say that a belief in the germ-theory in no way renders necessary a belief in a multitude of disease-germs botanically distinct: it is far more probable that germs in the specific diseases owe their properties to the material which nourishes them. Just as a common fungus may be rendered poisonous by matter on which it grows, so the disease-germ may acquire its properties from the fluids of the organism in which it lives. Nor does the germ-theory postulate the doctrine that infectious diseases cannot arise *de novo*; it simply postulates a particle of living matter, which, with certain surroundings, can acquire special morbid powers with self-increase in the bodies of those whom it attacks.

The last objection—the final blow—is derived from the observation of Chauveau and Sanderson, that the blood in sheep-pox is non-infecting, whilst the fluids of the tissues, which are the seat of the disease, are highly infecting. To assert that this observation is fatal to the germ-theory appears to me about equivalent to asserting that the current of a river does not carry the seeds of plants which dot its banks, because observation and cultivation of a tumblerful of the water fail to demonstrate such seeds or plants. The *contagium* of sheep-pox, once absorbed, is carried by the blood-stream to the tissues, where, and where only (in this special disease) it develops, multiplies, and exercises its morbid action. By parity of reasoning, Dr. Bastian, discovering no ova of trichine in the blood of a hog, could deny the germ-origin of trichinosis disease.

Dr. Bastian persistently quotes Liebig as the opponent *par excellence* of the germ-theory of fermentation, and places the two theories—the "vital" of Pasteur and the "physico-chemical" of Liebig—as if they were absolutely antagonistic the one to the other. I beg to ask Dr.

Bastian's authority for this. In his latest paper, Liebig distinctly asserts that in the case of saccharine fermentation it is *only* by the agency of the plant-organism that the phenomena are induced. The state of molecular motion by which fermentations are initiated is supplied by *vital activity*; and "in this sense," says Liebig, "Pasteur's view is neither inconsistent with mine nor antagonistic thereto". I am not aware that Liebig has ever given his adherence to the hypothesis of spontaneous generation. Clearly, therefore, Dr. Bastian must not fight behind the shield of Liebig, but must take the field alone.

There is a portion of Dr. Bastian's address which gives hope and joy to the "vital" school. He admits that such zymotic maladies as the silk-worm disease and malignant pustule are essentially due to germs. Will his further conversion be long delayed?

I am, etc.,

Oct. 9th, 1871.

A. ERNEST SANSOM.

## THE DENTAL PROFESSION AND THE COLLEGE OF SURGEONS.

SIR,—Your admirable article on Dental Diplomas in the last number of the BRITISH MEDICAL JOURNAL, cannot but be gratifying and encouraging to all who take an interest in the progress of dental surgery. But the statistics upon which you base your statements are not quite correct; and, as you have done me the honour of mentioning my name with the figures, you will excuse my wishing to rectify them as far as I can, though, unfortunately, we have as yet no trustworthy source of accurate information. At the request of the Dental Diploma Committee, I am endeavouring to compile a list of all persons calling themselves dentists; but, as yet, I can only furnish you with approximate numbers. Thus, in England I have collected over 1600 names; but, from the additional information which I am constantly receiving, I should say that the number of individuals of all classes calling themselves dentists are between 2000 and 3000. As to Scotland and Ireland, I have only been able to find the names of 150 practitioners in Scotland and 25 in Ireland (your printer has accidentally transposed these numbers); but I feel sure there must be many more.

Permit me to say one word more upon this list which I am compiling. Many qualified men practising as dentists, and many unqualified, but highly respectable and skilful dentists, feel aggrieved at the bare notion of their names being associated, even in a manuscript list, with hundreds of ignorant and unskilful men, who call themselves, and practise after a fashion as, dentists. In the present anomalous condition of dental surgery, however, this is a grievance of which they cannot complain with justice. If you take the *London Post Office Directory* you will find the *élite* of the dental profession in the same list as their mechanical workmen and those who combine dentistry with the business of a chemist; and the public have no means of judging as to the relative merits of these respective professors of dental science. It is the same in all provincial local lists; and even in our dépôts whence we are supplied with materials, all classes alike are reckoned as dentists on the lists of their customers. These lists are not open for our use, nor of service for statistical purposes; and it was imperative before the Dental Diploma Committee could advance one step on its course that it should be in possession of certain trustworthy statistics. This is the work, as yet incomplete, from which I have given you such particulars as have hitherto been collected, with more difficulty than anyone who did not actually do the work could conceive. For the satisfactory completion of this compilation I earnestly request the assistance of everyone who has the interests of the dental profession at heart. In a few days a rough list of the dentists in his neighbourhood will be sent to every known dental practitioner, so that he may make what additions and corrections are needed; and I trust that by each individual taking a little trouble, much of the collective labour which falls to me will be lightened. Thanking you once more for your able advocacy of our cause,

I am, etc., CHARLES JAMES FOX, M.R.C.S., L.D.S.

27, Mortimer Street, Cavendish Square, W.

THE MIDDLESEX HOSPITAL.—A gift of fifty brace of partridges has been kindly sent for the use of the patients of the Middlesex Hospital, by G. A. Dodd, Esq.

TESTIMONIAL.—Dr. James Sawyer, who has lately been appointed Physician to the Queen's Hospital, Birmingham, and Extra Acting-Physician to the Birmingham and Midland Free Hospital for Sick Children, has been presented with an address, a microscope, a time-piece, and the publications of the New Sydenham Society (forty volumes), as a "testimony of the high appreciation of the manner in which, for the last three years, Dr. Sawyer had filled the office of Resident Physician to the Queen's Hospital."

## OBITUARY.

### FRAZER THOMSON, M.D., PERTH.

WE announce with regret the sudden death on Tuesday afternoon, from disease of the heart, of Dr. Frazer Thomson, of Perth. He had just arrived by train from Edinburgh, and expired in the railway station. For many years Dr. Thomson acted as out-door surgeon to the Perth Infirmary, but he had resigned the office some years ago. He was engaged in an extensive practice. Benevolent, and taking an active and earnest interest in many of the philanthropic institutions of the city, Dr. Thomson gained the respect of the community.

### THOMAS BUSHELL, M.R.C.S.Eng.

THE late Thomas Bushell was apprenticed nearly sixty years since to Mr. Coles, a surgeon, near Covent Garden. He was a pupil of the late Joshua Brookes, and of St. George's Hospital. Having passed the examinations at the Apothecaries' Hall and the College of Surgeons, he commenced, fifty years ago, practice at 117, Crawford Street, and continued there to the time of his death, being highly esteemed by all around. On the formation of the Royal Botanical Society in Regent's Park, he became one of its earliest members. Being much attached to botany, he was soon elected on the Garden Committee of the Society, to the welfare of which he was much devoted. He was constant in his attendance; and, on the day previous to his death, he was present at a meeting on business. Early on Thursday morning, the 5th instant, he awoke, and feeling ill, rang for assistance, but expired very shortly afterwards, in the 75th year of his age. He was buried at Highgate Cemetery.

### ROBERT BUCHANAN, M.D., KNOXLAND, DUMBERTON.

THE subject of this memoir was born in Glasgow on April 13th, 1794. He was the son of Mr. William Buchanan, a much respected citizen. He received his education at the Grammar School, and completed it in the University of that city. As was once the practice with students of medicine, he served an apprenticeship to Dr. M'Dougall, a surgeon and druggist in Glasgow. In 1815, after being duly qualified, he commenced practice in Dumbarton, then a very limited field in population. He became well and favourably known not only in the town of Dumbarton, but throughout the county, and gained an extensive practice among all classes. In these times the means of transit were very limited, and many a long, exhausting, and ill-requited journey he cheerfully undertook wherever and whenever his aid was sought. Many years ago, he received the appointment of Surgeon to the garrison in the Castle of Dumbarton and to the County Prison. He was the official surgeon of the local magistracy; and often at the assizes he received high commendation from the judges for the simplicity, skill, and accuracy of his reports in criminal cases often of much delicacy. He was placed on the Commission of the Peace for the county at a period when its roll was very select. He possessed a very refined taste for music and painting, and other branches of the fine arts, to which he devoted his leisure hours to the close of his life. Of a manly frame, he had the frank and easy manners of the perfect gentleman of the olden school. In all circles, his acquaintance and company were eagerly sought and much appreciated. In 1829, he married Mary, the second daughter of Mr. John Dixon, of Levensgrove; she survives him with two daughters, one married and resident in England. Some years ago, on his completing his fiftieth year of practice, his medical brethren of the locality, as well as from a distance, presented him with an address at a public dinner. A year before his decease he had a severe attack of illness; but this gradually abated, and his friends were hopeful that he had recovered. In the latter end of the summer of the present year, his malady returned in an aggravated form; and, after much suffering, he died on September 10th, and was interred in the new cemetery of Dumbarton on the 15th. A numerous company followed the body. A party of the Royal Artillery showed their respect to his memory by carrying the coffin from the gate of the cemetery to the tomb. In passing to the cemetery, the shops were shut and the streets of Dumbarton were crowded by the inhabitants. In politics, Dr. Buchanan was a decided and consistent Tory, and a staunch member of the national church; but he never obtruded on others his opinions either political or ecclesiastical, and was ever as ready to allow liberty of judgment and free expression of sentiment to others as he claimed for himself.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received their certificates to practise, on Thursday, October 5th, 1871.

Addy, Boughton, Southport, Lancashire  
Bradbury, John Bailey, Leeds  
Marshall, John, Bolney, Suffolk  
Slater, John Samuel, Bath  
Vores, William Mallam, Great Yarmouth

The following gentlemen also on the same day passed their first professional examination.

Clyma, Handsford Hosking, Guy's Hospital  
Welch, Samuel, London Hospital

### MEDICAL VACANCIES.

THE following vacancies are announced:—

ABERDEEN ROYAL LUNATIC ASYLUM—Assistant Medical Officer.  
ARDWICK AND ANCOATS DISPENSARY, Manchester—Junior Surgeon.  
ATCHAM UNION, Salop—Medical Officer for the St. Mary's District.  
BALTINGLASS UNION, co. Wicklow—Medical Officer for the Kiltegan Dispensary District.  
CAVAN UNION—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Ballyhaise Dispensary District.  
CHARING CROSS HOSPITAL—Assistant Physician.  
CORNWALL LUNATIC ASYLUM, Bodmin—Assistant Medical Officer.  
GOVERNMENT DIOCESAN TRAINING COLLEGE FOR GOVERNESSES, Derby—Surgeon.  
DEVON COUNTY LUNATIC ASYLUM—Assistant Medical Officer.  
ENNIS UNION, co. Clare—Medical Officer for the Newmarket-on-Fergus Dispensary District.  
GENERAL HOSPITAL, Nottingham—Resident Surgeon-Apothecary; Assistant House-Surgeon.  
GORT UNION, co. Galway—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Ardahan Dispensary District.  
GREAT NORTHERN HOSPITAL—House-Surgeon.  
GUEST HOSPITAL, Dudley—Resident Medical Officer.  
INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, Margaret Street, Cavendish Square—Visiting Physician.  
LAMBETH, Parish of St. Mary—Medical Officer of Health.  
LIVERPOOL NORTHERN HOSPITAL—House-Surgeon.  
MALE LOCK HOSPITAL—Resident House-Surgeon.  
MARLBOROUGH UNION, Wilts—Medical Officer for District No. 2.  
OMAGH UNION, co. Tyrone—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Eastern Division of the Omagh Dispensary District.  
PEMBROKE UNION—Medical Officer for District No. 5.  
POCKLINGTON UNION, Yorkshire—Medical Officer and Public Vaccinator for the Pocklington No. 2 District and the Workhouse.  
PRESTON AND COUNTY OF LANCASTER ROYAL INFIRMARY—Two House-Surgeons.  
RATHDOWN UNION, co. Dublin—Medical Officer for the Killiney Dispensary District.  
ROMFORD UNION, Essex—Medical Officer for District No. 7.  
ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road—Surgeon.  
ROYAL SURREY COUNTY HOSPITAL, Guildford—House-Surgeon.  
ST. GEORGE DISPENSARY, Mount Street, Grosvenor Square—Physician-Accoucheur.  
SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY—Assistant House-Surgeon.  
TIVERTON UNION, Devon—Medical Officer for the Silverton District.  
WARMINSTER UNION, Wilts—Medical Officers and Public Vaccinators for the Corsley and Warminster Districts and the Workhouse.  
WARNEFORD HOSPITAL, Leamington—Medical Officer.  
WEYMOUTH UNION, Dorset—Medical Officer and Public Vaccinator for the Melcombe Regis District.  
YORK COUNTY HOSPITAL—House-Surgeon,

### MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.*

CARRE, Fenwick, L.K.Q.C.P.Irel., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Bellaghy Dispensary District of the Magherafelt Union, co. Londonderry.  
KISBY, Wm. J., L.F.P.S.Glasg., L.A.H.Dub., appointed Apothecary to the Workhouse and the Gort Dispensary of the Gort Union, co. Galway.  
\*TAIT, Lawson, Esq., appointed Surgeon to the Birmingham Lying-in Charity.

### BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.*

#### BIRTHS.

DAY.—On September 1st, the wife of \*W. Henry Day, L.R.C.P.Ed. Chapel Street, Pentonville, of a son.  
MAPOTHER.—On October 11th, at Merrion Square North, Dublin, the wife of \*E. D. Mapother, M.D., of a daughter.

#### DEATHS.

GREAVES, Augustus G., Esq., Surgeon, at Derby, aged 59, on October 1st.  
YOUNG, Andrew Kerr, M.D., late of Glasgow, at Southend, Essex, aged 69, on October 1st.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY** .....Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**TUESDAY** .....Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**WEDNESDAY**..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**THURSDAY**....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**FRIDAY**.....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.

**SATURDAY**....St. Thomas's, 9.30 A.M.—St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY**—Medical Society of London, 8 P.M. Casual Communications. Mr. John Gay, "On Cruel Venosity"; Dr. Richardson, "Preliminary Notes of a Research as to the possibility of Destroying Animals intended for Human Consumption without the infliction of Pain."

**TUESDAY**—Pathological Society of London, 8 P.M.

**THURSDAY**—Harveian Society of London, 8 P.M. Clinical Communications.

## NOTICES TO CORRESPONDENTS.

*All Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.*

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**TO PURCHASERS**—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with halfpenny stamps for the amount.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

**MR. W. BOURNE** (Ambletside).—The Swiss condensed milk is a sufficient substitute for fresh milk (when the latter is not procurable) for hand-fed infants. It is made from cow's milk, and its price is rather below that of fresh milk in great towns.

## THE TESTIMONIAL TO SIR JAMES PAGET.

**SIR**,—I have just read "A Charitable Proposition" of H. F. S. referring to the above-mentioned testimonial, in which he advocates its being thrown open to the whole of the profession, instead of being limited to those who have been connected with St. Bartholomew's. I do hope this suggestion may not be carried into effect; at any rate, so long as it has been submitted to the approval of all those who, like myself, have already subscribed to the testimonial, on the understanding of its having a special connection with the hospital.

I am quite ready to agree with H. F. S. that Sir James Paget belongs to the "scientific world, both here and abroad," as well as to the "profession at large"; and if H. F. S. will only take the necessary steps to start the matter, I have no doubt he would have no difficulty in getting up a handsome testimonial from the whole of the profession; but I trust he will not think me selfish in expressing a hope that we may keep ours to ourselves.

As an old student of St. Bartholomew's, and a resident in the College there during part of the time that Sir James was Warden, I think he belongs more especially to us; and I do believe that there is a special corner in his heart, and a large one too, for dear old St. Bart's, and every one connected with it; and that a testimonial from the old students would, for this reason, give him especial pleasure.

I have written this entirely on my own responsibility, and without having been able to communicate with any one on the subject. Your columns will show whether I represent the views of the old students, or not; I feel sure I have not mistaken the feelings of Sir James Paget.

October 9th, 1871.

I am, etc., G. T.

## FOREIGN DEGREES.

**SIR**,—In reply to your correspondent "Physician," I would tell him not to expect to get the Baccalauréat degree easily. He will have to undergo an examination very like that for the Licence of the Royal College of Physicians of London, embracing all subjects of medical study, and extending over a week. Besides, he will be questioned at the bedside, and have to do operations on the dead body; and then, if he be not well up, he is plucked. In fact, one has to know and do a great deal more for the Baccalauréat M.D. than many of our seniors who obtained their Scotch degrees on much more reasonable terms, and when they were just as useless in England as the Continental ones are now. It is, indeed, high time that some British University should do the right thing and admit qualified men, without the baggage of nonsense, to the examination for its degrees. The rising generation of medical men will never be satisfied till this is done.

I am, etc.,

ANOTHER PHYSICIAN.

**NOTICES of Births, Marriages, Deaths, and Appointments, intended for insertion in the JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.**

## LUNACY CERTIFICATES IN IRELAND.

**SIR**,—Would you or some of your numerous correspondents kindly inform me if the Bill introduced by Sir Dominic Corrigan last Session, by which Irish Poor Law Medical Officers are entitled to a fee of two guineas for examining and certifying in cases of lunacy at the request of the local authorities, has yet become law; and if so, how is the fee to be obtained? I am, etc., A MEMBER.

\* The Bill was withdrawn, and will be reintroduced.

## POOR-LAW MEDICAL OFFICERS AND THE SANITARY SERVICE.

**SIR**,—I entirely agree with Dr. Gourley and with the recommendations of the Royal Sanitary Commission, that the medical officers should be the local sanitary officers for their district. Not only would the appointment improve their usefulness, influence, and position; but, whatever be the future sanitary organisation of the country, the district medical officer is far the most likely to foresee the propriety or necessity of sanitary alteration or improvement; he alone can carry them out promptly; and, in crushing out the origin of a contagious epidemic, for instance, promptitude is of the last importance. An officer for a large district, as a county, could not carry out sanitation with sufficient promptitude.

I have always thought it a great pity also that the Poor-law medical officers who are public vaccinators should not be registrars of death also for their district. Such an arrangement would secure the proper vaccination of infants, without the inconvenience which is now often experienced.

I am, etc.,

POOR-LAW MEDICAL OFFICER.

## MEDICAL WOMEN.

**SIR**,—Presuming that you will give fair play to this discussion, I ask you to publish the following reply to the editorial comments which are annexed to my letter at page 396.

1. I have not surrendered any point for which I have ever contended. To make clear my own position, I cite the following extracts from an address delivered by me at the Hanover Square Rooms, in October 1866:—

"The teaching operations recently commenced by the Female Medical Society have been described as 'an attempt to revive the old midwives'—a description as false as to say that the Royal College of Surgeons was designed to revive barber surgery. The Female Medical Society, without setting any limits to the medical education of women, or to the future extension of the college it has recently commenced—without in any way obstructing, or even refusing to co-operate with, those who wish to agitate for the admission of women to University degrees, and to the general practice of medicine and surgery, precisely as now followed by men—has organised its present rudimentary teaching operations for the purpose of meeting a great and pressing social want, and of superseding what of the 'old midwife institution' has not necessarily perished, in presence of the educational advantages which have long been monopolised by men. It is now working to induct educated intelligent women into a full knowledge of modern obstetric science and the accessory branches of medicine; and, while attempting to do for female midwifery what the now wealthy and powerful corporation of the Royal College of Surgeons has done for barber surgery, and thus to raise women to a level in midwifery with medical men, it will rest for the present on the assurance that, if a good and true basis be laid down, the requirements of society will bring about a natural development of the plan. . . . Supposing a separate and complete medical school accessible, woman—in order to make herself passably acquainted with the whole circle of medical science, and to obtain the status of a general medical practitioner—must devote a term of five years to study, in displacement of many pursuits which, by common consent, are considered to be more appropriate for her probable future. She must expend a sum of at least £500 in supporting herself during that time, and in payment of professional fees; and, when legally qualified—unless accidental notoriety or personal genius enable her to outstrip average men—she must be prepared to devote a second five years to converting general information into practical knowledge, and to acquiring skill in her profession and confidence from the public; then, and then only, does a really professional education begin to return a profit upon its cost. In fact, nothing is clearer, to those who know the bearings of this question, than that general medical practice is the work of a lifetime, and that its responsibilities are not a something to be set down and taken up again at convenience. . . . But, beyond the organisation of a separate medical college, in conformity with the regulations of the Apothecaries' Company, there is nothing to obstruct women from entering fully into the profession, and undertaking all cases which are now treated by men. Many exaggerated statements have recently been floated upon the organs of the general press, and the passing of the examination for an apothecary has been represented as a prodigious feat. . . . Practically, there is nothing in that examination which may not be passed by any fairly educated person of ordinary capacity."

The objects which I have advocated are strictly practical ones. They are—1. To supersede the present ignorant midwives by skilled obstetrices. 2. To add to the employments now open to the women who turn governesses. 3. To do away with the unjust exclusion by which women are now prevented from practising medicine—an exclusion totally uncalled for, and which violates the broad principles of free trade and personal liberty, while it imposes a disability and injustice upon the weaker sex. How far, when this exclusion is done away with, women may avail themselves of their liberty, is another question, and one which they should settle for themselves.

4. That the present exclusion is supported by an *animus* on the part of the medical men is, I think, shown by the whole current of affairs. Take the tenor of your own editorial in the JOURNAL of March 9th, 1867. There—referring to the action of the Apothecaries' Company—you remark approvingly:—"This amounts, as it is avowedly intended, to an exclusion of female candidates from the only diploma hitherto open to them." As the JOURNAL informs us that you interpret the sentiments of "more than four thousand medical men, the *élite* of the profession," your *dictum* must be conclusive. Last Saturday, also, you pounce upon our skeleton prospectus for a course on obstetrics and its accessories, and you tear it to pieces, as if we were clamouring for its recognition as a full medical school. Then, after demonstrating the non-existence of that which had never been asserted, you say—"The colleges cannot be blamed for not recognising what does not exist."

5. You ask as to the number of lectures. The obstetric course by Dr. Murphy comprises seventy-five lectures, and is equal to that given by him at University College. The supplementary course—of three sections—comprises forty-eight lectures; and the extra courses on chemistry, materia medica, diseases of women,

and diseases of infants, each comprise twelve lectures. There is also the following general provision, which you must have overlooked:—

"The minimum curriculum recommended for ladies intending to practise midwifery comprises:—1. Attendance during two winter sessions upon all the obstetrical and supplementary courses of lectures. 2. Attendance during the intervening summer upon clinical practice at a lying-in hospital or maternity charity, with personal attendance upon at least twenty-five deliveries, under the superintendence of an adequately qualified midwife or registered medical practitioner.

"Additional classes will be formed at the request of twelve students."

4. As to what ladies should do: if they will only take to heart the last sixteen lines of your article "*Minerva medica*", they will adopt what I have continuously urged. But, unfortunately, certain ladies, holding what are called "advanced views", have joined in depreciating the obstetrical work of the Female Medical Society, simply because it did not put upon paper a big, hollow scheme like that for the Women's College at Hitchin, which has now failed so disastrously.

4. Fitzroy Square, W., October 2nd, 1871. I am, etc., JAMES EDMUNDS.

\* \* Dr. Edmunds has a singular mode of expressing himself; but we shall not quarrel with his form of speech. We shall only reply briefly:

1. That we do not approve of the exclusion of women from examination for medical or any other degrees, when they have gone through the required curricula of study, and are able to satisfy the same intellectual tests as men. We do strongly disapprove of mixed classes of the two sexes for medical instruction.

2. That we did not "pounce upon" the prospectus of the "Female Medical Society", but that it was forwarded to us by Dr. Edmunds, who expressly challenged our opinion of it. Our candid opinion is, that it describes a farcically incomplete course of education, dangerously delusive in essence, in title, and in method; that the treatment of the diseases of women and children requires the same amount of medical education as the treatment of the diseases of men; and that for this purpose, the sort of education described in the prospectus is rather worse than nothing, and more dangerous than can easily and shortly be stated.

3. We cannot approve of the use made of the name of an aged gentleman, once a professor at a medical school, but who has fallen in the battle of life, and for whom a collection, to enable him to end his days in peace, has now for some months been actively and publicly made among the charitable members of the profession and through the columns of the medical journals.

4. We look upon the Female Medical Society, judged by its own prospectus, as the greatest obstacle which has yet been raised to the true interests of female medical education; and, however good may be Dr. Edmunds's intentions, we hold him to be in effect the worst enemy of the cause which he comes forward to champion.

#### THE TREATMENT OF CHOLERA.

SIR,—Having read with interest accounts of treatment in cholera in your JOURNAL lately, I think the following case may be of interest. Hearing, while at a midwifery case, that a man had been seized with sickness and purging, and cramps in his limbs and body, I sent a dose of chlorodyne, which I always carry with me at this time of year; and, as I returned home, called to see how he was. The purging still continued, though not so severely, and the sickness was rather better, but the cramps continued, and were very distressing. I left another dose of chlorodyne, and gave directions to let me know if he were no better in the morning. I then sent a mixture of carbonate of soda, with small doses of hydrocyanic acid, and ordered his body to be fomented, and rice and milk to be given as food, and toast-water *ad libitum*. The following day, he appeared something better, as, the cramps having quite left, he was free from all pain, the motions being reduced to a thin watery discharge, that ran from him as he lay; it was colourless, but of a very offensive odour. His tongue was warm, but the pulse fluttering and scarcely perceptible. He was ordered brandy in the rice-milk. The next that I heard of him was, that he was dead, after about fifty-six hours' illness. It appeared that, some weeks previously, he had been employed to empty a well into which sewage had for some time found its way; that, when opened, the stench from it was particularly offensive, causing, at the time, sickness to one of the bystanders, and subsequent ill effects to others present. The case was undoubtedly one of blood-poisoning from local cause; and I returned it as choleraic diarrhoea. I was very sorry afterwards that I had not given a dose of castor oil, which I was as near as possible doing when the discharges became offensive. The reason of my writing this is to further endorse the eliminative treatment in cholera as a blood-poison; it may be instructive in a negative point of view. In ninety-nine cases out of a hundred, I find small doses of tincture of opium, chalk mixture, or chlorodyne and mint water efficacious in the sickness and purging so common at this time of year. Beeston, Notts, 28th September, 1871. I am, etc., JOHN ORTON.

#### HOSPITAL TENTS FOR EPIDEMIC DISEASE.

SIR,—I am glad to see your suggestion that it would be wise to pitch a hospital tent near Bridgwater, if a small-pox hospital be needed before a permanent structure is provided. It is an excellent suggestion, and might be wisely adopted to a larger extent than you propose, and at other places. A friend, who was engaged with the American ambulance corps during the siege of Paris by the Germans, informs me that their hospital-tent was at once well ventilated, sufficiently light, without glare, and comfortably warm. It consisted of thin double canvas; the air interposed, being almost motionless, greatly obstructed the passage of heat, except what was necessarily lost by a free but gentle passage of air through the canvas, and by its ventilating openings. The tent had no windows, and needed none, as the thin canvas allowed a gentle light to pass. Another tent with windows was used for operations. The tent was warmed by a stove, with long piping passing in a sort of channel in the ground underneath its floor. This mode of warming, and the double canvas for retaining the heat, seem to be the only important peculiarities, but they are important; as, when air is not chilled by contact with cold walls or windows, that which has been warmed by respiration or contact with the skin is not cooled and made to descend so as to be breathed again, but is at once carried away by the ventilating openings, and its place supplied by fresh and pure air warmed from below; moreover, by warming from below, the floor was always, as it ought to be, the warmest part of the room: while, the stove and flues not being near anything inflammable, the danger of setting the hospital-tent on fire was avoided, a subject of great anxiety when those unable to move are in a tent with an ordinary stove. Moreover, the economy of fuel is often a matter of great consequence, as, indeed, it was in Paris.

Such hospital-tents would be invaluable for all cases where an unusual amount of hospital accommodation is needed for a short time only, as they can be quickly and cheaply erected wherever required, easily removed when wanted elsewhere, and easily disinfected after having received cases of infectious disease; for example, by soaking the canvas in chloride of zinc solution, by which, also, it would be rendered unflammable. I am, etc., P. H. H.

NOTICE TO ADVERTISERS.—Advertisements should be forwarded direct to the Printing-Office, 37, Great Queen Street, W.C., addressed to Mr. F. H. HEATHCOTE, not later than *Thursday*, twelve o'clock.

#### OFFICIAL OBSTRUCTIVENESS TO VACCINATION.

SIR,—At a juncture when small-pox has been raging from John O'Groat's to Land's End, that any arbitrary regulations as to the periods of vaccination and in distinct contravention of the Act should be enforced by the Inspectors of Vaccination, seems inexplicably contradictory.

Allow me to instance my meaning by informing you that last spring one of the Inspectors made his periodical visit and inspection in my district, and, having satisfied himself, informed me that the Board of Guardians would make a new contract for the performance of vaccination, which at midsummer they accordingly did with me, and with the other medical officers of the union. The terms of the contract were that all patients were to be brought to my surgery to be vaccinated, only during the months of April and October in each year; thus at once violating that clause of the Act which expressly directs that children are to be "vaccinated within three months of the date of birth." A child born at the beginning of May would be five months old by the end of September. Now, in country districts it is found most convenient to vaccinate when a few cases present themselves, so as never to have any over three months unvaccinated.

I have always satisfactorily performed vaccination from arm to arm after having first procured well-charged points, which I generally have done for many years from the establishment in Russell Place, Fitzroy Square. Two preceding Inspectors had awarded me the extra gratuity from the Privy Council for successful vaccination.

As to making it compulsory for children to be brought to the surgery in all cases, this is almost impracticable, as parents cannot at all times leave their homes; the weather may be too inclement sometimes, especially at these months. Under these circumstances, to prevent trouble and delay, I contrive, as often as possible, to have a child vaccinated near where others require to be done, so that they may more easily be brought together; and have in some cases carried recent lymph, not quite dry, in a bottle.

I feel sure that, if mischievous impediments be thrown in the way, it will increase the difficulties with which medical men already have to contend, as well as perpetuate the scourge which we are endeavouring to stamp out.

October 1871.

I am, etc.,

A MEMBER.

DR. B. W. FOSTER is thanked for his courteous letter.

#### GRATUITIES TO VACCINATORS.

SIR,—From time to time, we see notices in the papers of bonuses or extra grants to public vaccinators. Now, I have been for some years a vaccinator in a small way under the Poor-law Board, but have not had the good luck to see a penny of any bonus. I am just now entering on a fresh contract with the guardians, and have been supplied with the modern form of register-book; so I hope that, under the new régime, I may come in for what I have only yet heard of. Will you kindly inform me, through the medium of our JOURNAL, what I must do to gain the desired end? I am, etc., ASSOCIATE.

\* \* Observe strictly the rules of the department, and vaccinate carefully and successfully.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Altrincham and Bowden Guardian, Oct. 7th; The Philadelphia Evening Bulletin, Sept. 15th; The Wolverhampton Chronicle, Oct. 11th; etc.

#### COMMUNICATIONS, LETTERS, ETC., have been received from:—

# IMPORTANT NOTICE TO THE PROFESSION.

**DR. RIDGE'S FOOD** is rich in solids and earthy salts. The phosphates of potash and magnesia exist naturally, and are not introduced by any chemical process. As nature has produced them, so are they conserved and kept free. The nitrogenous substances are varied, consisting chiefly of soluble albumen and gluten. In the preparation of this Food, the outer covering of the grain used is carefully removed, for it is well known that the smut (which is a species of puccinia) lives upon the surface of wheat, and is apt to cause diarrhoea in children. The Food is so thoroughly desiccated that neither the *Acarus Farinae* nor the *Vibroni* can live in it. This renders this article of diet superior to all others, for it not only builds up healthy tissue, but prevents the introduction of any vegetable or animal parasite, which is often the cause of the incessant diarrhoea of children. Medical men, by sending their card to the Manufactory at Bermondsey, can receive a tin of food for trial, free of charge.

**Sold in Packets and Canisters by respectable Chemists and Grocers.**

## Tasteless Pills.—Cox's Patent.

Surgons and Chemists supplied with an excellent Aperient Pill, the formula for which will be forwarded, covered with a thin non-metallic film, rendering each pill perfectly tasteless, at 1s. 6d. a gross. Postage 2d. They present an elegant pearl-like appearance, and may be kept in the mouth several minutes without taste, yet readily dissolving in a short time, even in cold water. Any formula dispensed and directed, and samples, with a list of pills, from our formulae which are kept in stock, forwarded free on application.

Now ready, a strong leather-covered Pill Case, resembling a pocket book, filled with Tasteless Pills (exactly 7 gross), from 1s. daily used formulae, sent on receipt of remittance for £1 1s. Empty, 10s.

Cox, Son, and Co., Tasteless Pill Manufacturers, Brighton.

## KINAHAN'S LL. WHISKY.

This celebrated and most delicious old mellow spirit is the very CREAM OF IRISH WHISKIES, in quality unrivalled, perfectly pure, and more wholesome than the finest Cognac Brandy.

Note the words "Kinahan's LL. Whisky", on Seal, Label, and Cork.

Wholesale Depot, 6A, Great Titchfield Street, Oxford Street, W.

## Vaccine Lymph, preserved in

Glycerine, in Glass Tubes, 1s. each, or three for 2s. 6d. Fresh Points every Thursday, 2s. 6d. per doz.

Apply to Dr. WOODWARD, Public Vaccinator, Worcester.

## SAVORY AND MOORE'S PANCREATIC EMULSION.

Readily miscible in Milk, Water, and Wine.

**NOT DETERIORATED BY KEEPING.**

## PANCREATINE,

IN POWDER, WINE, AND COCOA.

See "Experiments with Pancreatic Juice."—*The Lancet*, October 16, 1869.

## IMPROVED LIEBIG'S FOOD.

"RESEMBLING MOTHERS' MILK as closely as possible."—Dr. T. H. BARKER.

No Boiling or Straining. Tins, 1s., 2s., 5s., and 10s.

## PEPSINA PORCI PUR.

Free from Starch. Requires no Lactic or Hydrochloric Acid to ensure its digestive activity.

Has more than **EIGHT TIMES** the digestive activity of the best specimens of the so-called Medicinal Pepsine, or Nutrientative Powder.

**143, NEW BOND STREET,**  
And all Chemists.

## BASS'S EAST INDIA PALE ALE.

**BARCLAY'S STOUT.**

Recommended by the first medical authorities for Invalids and Ladies nursing.

In 18 Gallon Casks, Bottles, Half-bottles, and Imperial Pints.

Also, **DEVONSHIRE CIDER.**

**BERRY BROS., & Co., 3, ST. JAMES'S STREET, LONDON S.W.**

# AN ADDRESS ON PUBLIC HEALTH AND ITS MODERN REQUIREMENTS.

*Delivered at the Annual Meeting of the Social Science Association, in Leeds, October 1871.*

By GEORGE GODWIN, F.R.S.,  
President of the Health Department.

*Progress in Sanitary Matters.—The Local Government Board.—Sir Charles Adderley's Scheme.—The Metropolis Water Act.—Sanitary Precautions.—Impure Water.—The Sanitary State of Leeds.—Partial Improvements.—The Example of Saltaire.—The Prevention of Diseases.—Dwellings for the Very Poor.—Recreation and Amusement.—Conclusion.*

It is tolerably well known that one department of the Social Science Association devotes itself to the consideration of questions relating to public health, discusses improvements in house-construction, drainage, and ventilation; means of recreation and amusement; the influence of external circumstances generally on health, and the legislative machinery necessary to effect desired ends in that direction. Called to the position of President of this department, it becomes my duty to address the Association; and I assure you I approach that duty with a full sense of the responsibility attaching to the position, and a vivid recollection of the admirable manner in which its obligations have been discharged by the able men who have preceded me; including, to speak only of recent times, Mr. Edwin Chadwick, Dr. Farr, Dr. Rumsey, Dr. Lankester, the late Dr. Symonds of Bristol, and Mr. Robert Rawlinson. Their labours, I do not hesitate to say, have materially assisted in bringing about an improved state of public opinion, and obtaining important enactments. The proceedings of the Association on some previous occasions have been treated as futile in journals of influence. It ought to be unnecessary now to combat on such ground. The earnest discussion of the wrongs, miseries, evils, and wants that afflict society, by men and women who have given lives of thought to the various subjects involved, cannot fail, and has not failed, to lead to good. It takes a long time to make the world listen, but it hears at last if the effort be not relaxed. If we look back over the fifteen years during which the Association has laboured, and note what has been done during that time in this special department alone—that of health—we shall feel satisfied that its labours have not been in vain, and, however depressed we may have been by the slowness of progress, and the enormous amount of work yet to be done, we shall find our views and hopes for the future cleared and strengthened.

*Progress in Sanitary Matters.*—The great object of our meetings and discussions is, by the production of facts and the collision of reasonings, to take a series of the most important subjects affecting the welfare and happiness not of this town alone, not of England, but of the whole human race, out of the domain of opinion into that of knowledge. Opinion means ignorance more or less. I may be "of opinion" it will rain to-day, but I "know" two and two make four. Gradually, but surely, this progress from opinion to knowledge has been going on in sanitary matters. Not many years ago there were numbers of educated and influential people, who were of opinion that there was no connection whatever between bad sanitary arrangements and ill health. At the present time we may, perhaps, go so far as to say that all admit, more or less fully, that this connection does exist. A whole host of questions, however, remain, correctly or incorrectly, matters of opinion; and it is with a view of their speedy removal from debatable ground, so that effective action may be at once taken, that this Association holds its meetings, and publishes the results of its deliberations. Thus: we have ceased to discuss as to the necessity of promptly getting rid of the sewage of towns, but the best mode of disposing of it is still with some a matter of opinion. This part of the inquiry, however, is gradually narrowing, and it may be hoped that the proceedings at this Congress will tend to bring about the right conclusion. In common with a large majority of those who have investigated the subject, I feel perfectly assured myself that the irrigation of land is the right use, except in some special cases, to which to apply sewage. Evidence that it may be thus applied with pecuniary advantage, and without injury to the health

of the neighbourhood, is accumulating day by day. The reports of the Sewage of Towns Commissioners, the Rivers' Pollution Commissioners, and the committee appointed by the British Association, all strengthen this view; and, amongst other indications, at a recent meeting of members of the Essex Chamber of Agriculture, it was resolved, after inspecting the sewage farm at Romford, "That, in view of the large amount of foreign wheat paid for every year by the population of this country, and the large amount of manure wasted in polluting rivers with town sewage, it is desirable that such pollution should now be prohibited by legislative enactment, and that the forty-five Sanitary Acts in existence should be repealed, and a general and comprehensive law enacted." It has been calculated by more than one competent authority that the amount we shall have to pay for foreign wheat this year will be above thirty millions sterling, a circumstance worth this passing allusion as showing the largeness of the interest involved in our inquiries.

*The Local Government Board.*—Events are tending, it may be hoped, towards the desired unification of existing Acts referred to in the resolution quoted. The new Local Government Board, of which the Right Hon. James Stansfeld, M.P., is president, will take the place of the Poor-law Board, with wider powers, specially embracing the statutes having reference to the sanitary arrangements of parishes, such as those relating to the sewers, nuisances, labour in workshops and factories, baths and washhouses, common lodging-houses, adulteration of food, and smoke-nuisances. The supervision of these matters will be transferred from the Local Government Act office and the Medical Department of the Privy Council to the new Board, and thus the government of matters relating to each other, and hitherto performed by three separate departments, will be united in one body.

*Sir Charles Adderley's Scheme.*—A new Public Health and Local Government Bill is in the hands of Sir Charles Adderley, and, when modified and added to, will probably become law. This proposes to repeal twenty Acts of Parliament, from the Public Health Act, 1848, to the Sanitary Act Amendment Act, 1870, the new Act codifying these repealed Acts, for England and Wales (exclusive of the metropolis). The several officers and clerks are placed under the authority of the new President, and will have to be amenable to him. Next session of Parliament ought to settle the mode of preventing river-pollution, and of providing the metropolitan water-supply; but this latter may probably be deferred until the local government of the metropolis is settled. It is to be hoped that by the new Act the medical officer of health will be made independent of local boards and of private practice, so that no fear of damaging or offending his patients and his masters may tend to prevent the proper and complete discharge of his duty at all times. It has been pointed out more than once, and may be usefully reiterated, that unless the medical officer of health be precluded from private practice he cannot hope to secure the co-operation of members of the same profession, to whom he must look for information of outbreaks of disease, and who would seldom be disposed to introduce another medical practitioner to their patients with the fear of his rivalry before them. The Act should also enforce in every district the appointment of a public analyst, who might do much towards the prevention of the adulteration of food, the cause of a large amount of ill-health and loss. Lead-poisoned water is another producer of illness, which such an officer would be able to detect. I must add, with reference to the contemplated new Act, that a report has just now been issued by a joint committee of the British Medical Association and the Social Science Association on the report of the Royal Sanitary Commission. This joint committee was presided over by our eminent associate, Dr. Rumsey; and its report includes various suggestions and observations that call for the serious consideration of those who are engaged in the preparation of the Public Health Bill.

*The Metropolis Water Act.*—The Metropolis Water Act passed at the close of the last session of Parliament has good intentions, but how far these will be carried out remains to be seen. After the expiration of six months from the passing of the Act, the local metropolitan authority shall, whenever they are of opinion that there should in any district be a constant supply, make application to the water-company, requiring compliance with the terms of the Act. There is a right of appeal to the Board of Trade upon the application being made to a company requiring them to furnish a constant supply. The Board of Trade may order a constant supply to be given if, after inquiry, the metropolitan authorities refuse to act, or unreasonably delay acting, or if, by reason of the insufficiency of the existing supply of water in such district, or the unwholesomeness of such water in consequence of its being improperly stored, the health of the inhabitants is, or is likely to be, prejudicially affected. Before a company is compelled to carry out the Act, however, various regulations have to be observed; and the companies seem to have the power, if so minded, to delay the desired

boon by objections which will have to be removed. Let us hope that the duty imposed on them will be loyally discharged. Of the desirableness of a constant supply I have myself not the remotest doubt. Some difficulties will probably be met with in the first instance, but these may be speedily overcome. One provision of the Act must be hailed with unmixed satisfaction—the requirement by Clause 6, that every company shall immediately supply on Sundays, as on other days, sufficient pure and wholesome water for the domestic use of the inhabitants within their limits. The amount of discomfort endured, and the evil produced, through the non-supply of water on Sundays, in the courts and slums of London and elsewhere, could scarcely be exaggerated. I have in my time visited some thousands of houses, the inhabitants of which were uniformly without a drop of water between Saturday and Monday. The story of their misery had to be told for years, with both pen and pencil, before the remedy came. The present Act, after all, can only be regarded as provisional. The great question, how best to secure an ample supply of soft pure water to London, will have to be looked fairly in the face before long and grappled with, let the cost of carrying out the decision be what it may. It is simply a question of time, and the shorter the time the better it will be for the health, the comfort, and, in the long run, the pockets of the inhabitants.

**Sanitary Precautions.**—The importance of the subject we are considering—the public health—is so great, it lies so entirely at the root of all national progress, that it is impossible to speak too strongly upon it. At the present moment, moreover, it is invested with unusually pressing interest. After a terrible visitation which has desolated homes throughout the country—a visitation which, all evidence shows, was the result of ignorance, carelessness, and wilful avoidance of a known means of prevention, or, at any rate, of amelioration—we note at no great distance from our shores the presence of a much-dreaded disease; and I should be neglecting a duty if I allowed this opportunity to pass without inviting all who have power to aid in making such preparations as experience shows to be calculated, under Providence, to mitigate its severity should it reach us. Should we happily escape its visit, we should still derive advantage from the steps taken. When there is no immediate prospect of danger the cost of precautions is begrudged. A large class of persons would sooner run the chance of death than incur the certainty of having to pay a small sum. We are all of us gamblers, more or less, and like to take our chance. The most vigorous and intelligent action is required on the part of our health-authorities, and their hands should be strengthened by public expressions and outside aid. I am anxious not to be thought an alarmist. There is no occasion whatever for alarm; it is, indeed, to be strongly deprecated. But it would be suicidal to think, ostrich-like, that if we shut our eyes, no one will see us; that if we say nothing about a possible danger ourselves, nothing will be heard of it. The way to defeat it is to meet it well prepared. "It is not known", (says the Registrar-General, in a recent report (August 1871), "that where a place is clean, where the waters are pure, where the people are not crowded, where good administrative arrangements are made for the early treatment of attacks in the first stage of diarrhoea, the epidemic is disarmed of nearly all its terrors. But as English towns are still dirty, are dotted over with cesspools or fouled by bad drains, and the waters alike of wells and of rivers, from which towns draw their supplies, are soiled to some extent by sewage, we can at present expect no absolute immunity. Commissions and committees have left our water-supply much as it was; the hard waters of the rivers are not purified by Clark's process, nor are the pure, unpolluted streams brought uncontaminated down to the cities in the plains. Still, much may be done, if cholera pursue its customary course, by commencing at once all useful works of purification, so as to mitigate its virulence. And this is what all, in their several spheres, should aid in doing. The medical officer of the Privy Council, Mr. Simon, in his instructions on the subject, recently issued—wide attention to which would prove of great value—has dwelt so strongly on the part played by polluted water in propagating the disease, as to have led to the expression of fear, by an esteemed member of the Association, that the public may be induced in attending to this to neglect other important inquiries. Mr. Simon says: "The dangers which have to be guarded against as favouring the spread of cholera-contagium are particularly two. First, and above all, there is the danger of water-supplies which are in any (even the slightest) degree tainted by house refuse or other like kinds of filth—as where there is overflow, leakage, or filtration, from sewers, house-drains, cesspools, food ditches, or the like, into streams, springs, wells, or reservoirs, from which the supply of water is drawn, or into the soil in which the wells are situated—a danger which may exist on a small scale (but, perhaps, often repeated in the same district) at the pump or dip-well of a private house, or on a large or even vast scale in the source of supply of public waterworks. And, secondly, there is the

danger of breathing air which is foul with effluvia from the same sorts of impurity."

**Impure Water.**—Without here discussing whether the objection taken to the medical officer's expressions be sound or not, the evils resulting from the use of water containing ordinary faecal impurities are well known. Outbreaks of typhoid fever have been traced again and again to this cause. In many cottages in low-lying land, by the side of stream-lets which receive the overflow of house-drainage and other refuse, it is never absent, and cripples the working power of the country to a much greater extent than might be supposed. The serious outbreak of typhoid fever at Terling, in Essex, will be remembered, where, between December 4th, 1867, and January 13th, 1868, two hundred and eight persons, out of a population of nine hundred, were attacked; and was shown to be connected with the pollution, by sewage, of wells from which the drinking-water was obtained (*The Builder*, vol. xxvi, p. 105); and many other similar cases might be adduced, some of which were made public by myself at a time when the evil was not so fully recognised. A Norwich rector has quite recently shown how, within eight days, last August, the father of a family, a labouring man, and four of his children, died and were buried; the cause being, as the writer believes, "filth percolating into the well-water". The rector adds: "I can point to four parsonage houses around me here, where deaths have occurred entirely from this same cause." I have no hesitation in saying with him that the same evil exists in thousands of houses, where nothing of this kind is suspected until some severe illness breaks out and carries off its victims—sometimes not even then. The medical officer of health for Islington, in his last report, gives the particulars of a local outbreak of fever, which serve to show how small a quantity of water so polluted will do mischief. He traced the cause of the outbreak, with much care, to sewage which leaked into an underground tank, whence milk from a dairy was adulterated with water. The dairymaster very honestly aided the officer of health by giving him a list of his customers, and it was found not only that the fever was restricted to houses supplied by this dairy, but to individuals in these houses who used that milk, while others who used a richer milk from the same dairy, not diluted with water from the tank in question, were not attacked by the typhoid fever. London must not comfort itself with the notion, founded on the amount of the recent expenditure on the main drainage, that all its cesspools have vanished, and that its sewers are now good and in a proper state. Many of them are in a dreadful condition, and thousands of old cesspools yet remain. As a rule, wells sunk into town subsoils furnish contaminated water, and should be avoided.

**The Sanitary State of Leeds.**—The fine town in which the Association is now assembled suffers greatly from the existence of middens and other dangerous accumulations of refuse. I have on more occasions than one examined Leeds, and have noted these with sorrow in scores of cases. The condition of the river Aire is very unsatisfactory, nor is this to be wondered at by those who know the amount of filth daily thrown into it. Its foul condition is a heavy tax on the cloth-makers, dyers, and other manufacturers of the town. What is the amount of the tax it lays on the health and strength, perhaps the life, of the place, I will not here inquire. It is understood that the question how best to utilise the sewage of Leeds has long been under discussion by the Corporation. Let me express an earnest hope that a wise determination will soon be arrived at and acted on, and that the abolition of deadly cesspools and middens will be effected. A lesser evil here, but still one that nevertheless touches the health and the pocket, is very distressingly observable to strangers. I mean the enormous amount of unconsumed smoke allowed to escape into the air and disfigure the town. The appearance of many of the fine buildings, which would otherwise adorn the streets, is miserably changed by it, and the effect produced by the general gloom resulting at times upon the spirits, and consequently the health of the inhabitants, must be considerable. It is a misfortune, I am satisfied, and not an advantage, that the recent Local Act for the borough contains an exemption as to the consumption of smoke in favour of certain trades carried on here. The Royal Sanitary Commission, in their second report, when deprecating this exemption, speak of the manifest injustice thus done to similar works in the adjoining districts, competing in the same market as Leeds, under the more rigorous enactments of the public general statutes. The evil wrought by it in the town will be a stronger argument here, and ought to ensure its early abrogation. Very large sums, it is not to be denied, have been spent in Leeds on sanitary works, to the great credit of the town, but so much yet remains to be done that the death-rate is painfully high. The use of cellar-dwellings, of back-to-back houses—some of which I have visited—and the incompleteness of the sewerage already alluded to, are amongst the most prominent evils calling for immediate remedy. The death-rate in the Midsummer quarter this year was 23.2 in the 1,000, very much higher than it should have been; and yet we are forced to

recollect that, in parts of the town, the rate was more than double that amount, which means that thousands of persons died simply because they were placed under more disorderly circumstances than their neighbours; and this goes on year after year—surely a frightful reflection. It is well to remember that lessening the death-rate in Leeds, say only two per thousand, means saving 520 lives annually.

*Partial Improvements.*—Disappointment is sometimes felt that, after considerable expenditure in a district, the death-rate is not reduced to the extent expected. Careful inquiry would generally serve to show that the improvement made has been only partial. If the water-supply has been attended to, the drainage has been neglected; or if deficiencies in this respect have been remedied, the sewers are unventilated, or overcrowding, a deadly evil, has been permitted to an extent that counterbalanced the good effects otherwise produced. We may rest assured, however, that every improvement of this kind made does affect health, morality, happiness, and life, and so be encouraged to fight vigorously in aid of them. The story from Calcutta recently circulated that, in consequence of the effect produced upon the health of the town by recent improvements in drainage and water-supply, the undertakers were applying for compensation for loss of business, if not true, serves to show what, in public opinion, the result of the works has been.

*The Example of Saltaire.*—Many of the subjects relating to public health and social progress still offer problems for solution of extreme difficulty, and much good remains undone for want of its being known how best to do it. In confirmation of this, and for some other reasons, I am tempted to mention that I have for some time been authorised in writing, by an inhabitant of London, to state that he is willing and ready to appropriate to the improvement of the health and condition of the poorer classes of the metropolis a sum equal to that given by the late George Peabody for a similar purpose—or say half a million of money—when he can see a mode of satisfactorily effecting this without the fear of pauperising the classes he seeks to benefit. Means were taken to make this offer known to a limited extent, and a large number of suggestions have been sent to the proposer, but he is not yet satisfied as to the course that can wisely be taken. We must congratulate this individual on holding in his hand the power to achieve a glorious end, and I would add a hope that he may speedily come to a wise determination. A noble example of what may be done by an employer to improve the condition of those engaged for him is to be found in this district—I mean, of course, Saltaire—where intelligence and far-sighted benevolence have provided healthful homes, education for the children, innocent enjoyments, and means of culture. The time is coming when the history of the results of that establishment, in a sanitary and social point of view, should be written with a view to the guidance of others.

*The Prevention of Diseases.*—We lose, on moderate computation, a hundred thousand lives annually by preventable diseases, and millions of money in consequence of these deaths, and of premature disability in cases where death does not ensue. A million paupers receive relief weekly in England and Wales. With complete study of the laws of health, preventive medicine, and improved sanitary arrangements throughout the kingdom, the number of this melancholy army would soon be materially diminished. I have spoken of disability where death does not ensue. With reference to this let me say, we want registration of it. The registration of deaths which is now enforced is of the greatest value, but we need beyond that the registration of sickness, which would show the magnitude, not only of the grief and poverty to individuals caused by disease, but of the money-loss to the public. The desirability of this is fully recognised by the Royal Sanitary Commission, so that we may hope for legislation to enforce it before long. The connection between bad sanitary arrangements and ill-health is now largely admitted, as I have said, but not fully, or we should surely not find, in unnumbered places, accumulations of filth vitiating the air, large populations drinking polluted water, and debilitated by unhealthy dwellings, and preventable diseases annually carrying off their thousands, pauperising the families left, and injuring the whole community from the highest to the lowest. What is wanted is, after all, very simple. We want clean air, clean water, clean food—purity, in fact. And as we strive for purity in life, moral purity, so let us strive to obtain for society the advantages of physical purity. "Unto the pure all things are pure," says St. Paul (Titus i. 15), which may be true in regard to conduct, but at present the belief may not be safely acted on with reference to the air we breathe, the water we drink, or the food we eat. Moreover, how is it possible for moral purity to be retained in such dens as those in which multitudes of our fellow-creatures pass their lives? The assertion, as the home so the people, denounced as almost impious when first written, has come to be pretty generally accepted; but the homes in thousands of cases remain in the most wretched condition, and the natural results continue to follow. The injury done to our agricultural population by the want of

proper dwellings can scarcely be overstated; in fact, the whole condition of this part of the people is a disgrace to the age. I must restrict myself, however, to the question of health. I have visited hundreds of cottages with rooms scarcely of the height of a man, damp, cold, undrained, and overcrowded, with heaps of decomposing matter around, and where, in short, everything was being done to counterbalance the advantage offered by nature of a plentiful supply of pure air. In parts of the country where Portland cement and gravel, broken stone, or burnt clay are readily obtainable, a considerable saving in the cost of building may be effected by the use of concrete walls. It is absolutely necessary, however, that the concrete should be properly made and rightly applied; when this is the case, it is an excellent and enduring material; otherwise, it is worthless rubbish. It may be mentioned, as it will give confidence to those disposed to employ it, that the Metropolitan Board of Works now allow the use of it within their boundaries, and that the Enclosure and Tithe Commissioners permit money lent by them for the improvement of estates to be expended in the erection of concrete buildings. In both cases, however, the work is required very properly to be done under stringent regulations. It is to be regretted that the number of builders who have applied themselves to the economic execution of such work is still very small. By lessening the cost of erecting cottages, something is done towards inducing a proper provision of them. With good plans, wise superintendence, and the choice of proper materials, much may be done in this direction. Non-absorbent walls and floors are amongst the *desiderata*, and, above all things, such arrangements for the removal of the refuse that it shall not by any possibility contaminate the water-supply.

*Dwellings for the very Poor.*—Sound and healthful dwellings are required in towns for a lower class than have yet been thought of—the multitude who are unable to pay more than, say, a shilling a week as rent. There are a large number of these who require only one room, a man and his wife without children, single men and women, and widows. There seems no valid reason why a part of the Peabody Fund should not be applied to meet this want, and it is to be hoped the trustees of that fund will turn their attention to the subject at once. The desire to produce cheap houses by speculators has necessarily this bad result, that the efforts of the builder are all directed simply to that end, to discovering the means of erecting a dwelling at the least possible cost, not in providing to the utmost extent for the health and the comfort of the occupant. If the wages of a labourer be not sufficient to enable him, by the exercise of due prudence, to pay for a decent habitation, warm, dry, airy, and well drained, calculated therefore not to destroy his health and working power, and to send him to a premature grave, and his widow and children to the union to be maintained at the expense of the ratepayers, it is time they were made so. It is found to be wise and paying policy to provide horses with good stables, and pigs with healthful styes. Surely it ought to be thought necessary to do as much for the men who drive and feed them. Among minor evils in these homes, ill-ordered dust-bins should be mentioned as the fruitful source of sickness; decomposing matter, under present arrangements, being allowed to remain in them for weeks, sometimes months, to pollute the air. Better supervision is needed here. If the occupants of houses were to see that all consumable matter was burnt the danger would be lessened, and the quantity would be so much reduced that arrangements might be made for its removal day by day. Then, again, a vast deal of ill-health, to say nothing worse, results from the too early occupation of newly built houses. In the suburban districts of London, as in many of our large towns, small houses by the thousand are planted on the ground, often on heaps of unwholesome deposits placed there to fill up hollows whence brick-earth or sand may have been removed, are finished with pauseless rapidity, and, all reeking as they are, receive a family, often before the workmen have left. The danger involved was recognised long ago. An ancient foreign proverb says, as to a new house, "The first year for my enemy, the second for my friend, the third for myself." The speculative builder of to-day too often cares for neither friend nor enemy; the houses, like certain historic razors, are made to sell; to turn a penny is his sole object, and the buyer must look out for himself. Alas! for such a state of feeling; it unfortunately prevails in modern society to a much greater extent than is consistent with the right condition of public health, giving that word its full meaning.

*Recreation and Amusement.*—Among the arrangements for furthering the object we have in view, facilities for recreation and amusement must not be forgotten. Amusement must be had—will be had; and, if that which is rational and innocuous be not obtainable, less wholesome excitements will be resorted to. The provision of open and adorned places, picture-galleries, social gatherings, flower-shows, the practice of window-gardening, facilities for obtaining books, for the enjoyment and the study of music, "penny readings," cricket, swimming, archery,

drill, are all matters calling for the fostering aid of those who desire to see a good state of health prevailing, and would contribute their share in rendering the world happy, and leading to a higher type of manhood. Popular meetings for recreation have a further value in serving to bring classes together, counteracting the tendency to severance now in operation, and which has aided to produce the great danger that threatens society at this moment. It is the opinion of some who have inquired, that we are deteriorating physically as a people; that the number of men, for example, rejected on physical grounds from amongst those who offer themselves as soldiers or policemen, is greater proportionately than it was a dozen years ago. I am not disposed to accept this belief in our deterioration without reservation. It may be, and indeed unquestionably is, true in the case of thousands of our fellow-creatures pent up in close courts, garrets, and cellars, without pure air and water, or knowledge which would lead to an improvement in their condition, and of the thousands born of this class who go to fill prematurely the hospital and the graveyard. But there are other portions of the population of whom a different story may, it is hoped, be told. Still the destruction of health and life by preventable causes is enormous; and we are again made to feel, by the belief alluded to, the vital necessity of continuous efforts to bring about a better state of things.

*Conclusion.*—Every one may assist in this particular sphere in disseminating knowledge of the kind required, and building up a proper state of public opinion. By the exercise of this alone may we hope to obtain satisfactory laws, and to see those laws properly carried out. The want of education in what affects the human frame—the operation of the agents by which it is influenced—is unfortunately almost universal. If it were not so, laws to enforce sanitary requirements would be much less necessary than they now are. Sanitary science should be taught to all from the earliest years in schools of every grade. Until this is more generally done, we shall go on, as now, destroying one another, and blind to the fact, obvious to a Latin poet eighteen hundred years ago, that “life is not to live, but to be well.” This great question of health calls for the primary and unremitting attention of statesmen and legislators; it is far above party considerations, far superior in importance to the great majority of subjects which monopolise attention. Without education and health, no nation can advance and be happy; and to bring about those conditions should be the chief object of all government.

## THE RECOMMENDATIONS OF THE ROYAL SANITARY COMMISSION.

*Extract from an Address delivered at the Meeting of the Social Science Association in Leeds, October 1871.*

By GEORGE W. HASTINGS, Esq., President of the Council.

TURNING to the subject of Public Health, I may observe that there are facts which should constitute an useful warning against any attempt to subject our sanitary administration to the close control of a central office. The Act passed during last session has a taking name, as it was meant to have. But what if a Local Government Board means the preservation of local government in name and its abolition in practice? This may not be the object aimed at, but it is the ultimate mischief to be dreaded. It is, I think, unfortunate that this portion of the recommendations of the late Sanitary Commission has been adopted by the Legislature before the rest have been adequately considered; for the whole scheme in a great degree hangs together. Those recommendations were embodied in the bill that has been laid before Parliament by Sir Charles Adderley, and they have been commented on at length in a report lately issued by our Council. I beg for that document the attention it deserves from our members; it was mainly prepared by Dr. Ramsey, whose opinion on health questions, especially on all relating to the due organisation of a sanitary service, is probably more weighty than that of any other man in the kingdom. It reviews at length the recommendations of the Royal Sanitary Commission, and enters into minute detail on questions which I can only cursorily bring before you. I will, however, ask you to bear with me for a short space in reference to one or two leading points.

Let me, before doing so, bear willing witness to the value of the late Sanitary Commission. We may feel a legitimate interest in its work, for it was in compliance with a request urged by a deputation from our Council in the spring of 1868 that the commission was issued by the Crown. A deep debt of gratitude is due to its members, and especially to its chairman, Sir Charles Adderley, for the vast labour with which they have accumulated evidence of high value, and for their

learned, able, and most suggestive report. It is at once a reward and a justification of the pertinacity with which our Council, in conjunction with a sister society, the British Medical Association, sought for an authorised inquiry into the defects of our sanitary laws and administration, that the Commission has put on record a series of facts and opinions which will absolutely compel legislation.

But it will be admitted that, if we are to consolidate our law, and remodel our administration as to health matters, it were well to do so in the best possible way. Now, at the bottom of this whole subject lies the question, What is to be the area, or, as it has been the fashion lately to call it, the unit, of sanitary administration? Is it to be the parish, or the union, or the county, or some still larger district? This is not, as might at first sight appear, a question of convenience merely, but one of principle; one which, decide it how you will, must affect the whole complexion of future legislation. It will be admitted at once that ancient prejudice, not to be disregarded without reason, is in favour of small areas of local government. But in this case there is reason to set aside the wisdom of our fathers, because the great innovator, Time, has swept away the state of things on which their ideas were founded. In old days local administration was limited as much as possible to a small space, on account of the difficulty of locomotion. When the roads were so impassable in winter that it took a day to perform a journey of a few miles, it was obvious that the more work that could be done within the boundaries of the parish the better. The creation of turnpike roads in the latter half of the last century, and the subsequent improvement of parish highways, made such an administration as that of the Poor-law unions a possibility. But at the present time the general introduction of railways, even in remote districts, has made the access to our county towns an affair of an hour or two. Probably it is now as easy to collect the necessary attendants at quarter sessions and assizes from all parts of a shire, as it was formerly to gather the ratepayers of an average-sized parish in their vestry-room. Increased facility of locomotion has enabled us to use enlarged areas of administration, with all their advantages of greater economy in time, money, and efficiency, just as easily and conveniently as we formerly used small. When, therefore, Mr. Göschen, in his bill of last session, proposed to establish the parish as the unit of local government for the future, he created nearly as much astonishment as if he had asked us to revert to stage-coaches in lieu of the rail. His project was the more remarkable inasmuch as, when he framed his bill, the report of the Royal Sanitary Commission, based on information from his own office, was already in preparation, recommending the union as the primary area of administration.

It will be admitted that the same arguments which tell against the parish apply, though no doubt with diminished force, to the union. If the union be better than the parish, is not the county better than the union? The Sanitary Commissioners do not think so; but I confess to have searched their report in vain for any solid reason in support of their decision. It seems to me a halting between two opinions, and one, consequently, which on appeal to principle cannot be sustained. The question involves the fundamental reasoning of the science of society. If in the organisation of communities it be desirable to vest the primary functions of self-government uniformly in the smallest possible aggregation of individuals, that is one thing; but such a principle would compel the adoption of the parish as the unit of administration. If, on the other hand, it be believed that the establishment of the area which gives us the maximum of efficiency, economy, and convenience, is the true rule of legislation, then I venture to believe that the Poor-law union must stand condemned. Let us consider what are the advantages which large areas possess in comparison with small, especially in sanitary matters, and then we can judge whether the union comes up to the mark.

The first advantage is in the kind of men who are willing to serve on their governing bodies. It is very well to exhort men of standing and intellect on the duty of serving in parish vestries and such like bodies; they admit the obligation, but in nine cases out of ten decline to fulfil it. Human nature, as a rule, requires some reward for labour; and those who give their unpaid services to the public desire generally to be recompensed in one of two ways—the vulgar seek social position, and the high-minded aim at moral influence. The secret of the great position occupied by the House of Commons in this country, far beyond its legal claim, lies in the immense power it exerts as representative of the nation, the imperial questions it discusses, and the certainty that no man can be prominent in its ranks without possessing exceptional gifts of ability or character. The principle applies in less degree to other governing bodies. Take for instance the School Board of the metropolis. If the original intention of the Act had been carried into effect, and a separate board been instituted for every district in London, would you have had the same class of men who were glad to come forward as candidates for

a body controlling the education of three millions of people? The happy suggestion of Mr. Torrens has proved what may be done to elevate administration by the enlargement of local constituencies, and he deserves well of the whole country for compelling the adoption of this admirable example. Let us take care that it is followed in sanitary matters. Let us judge for ourselves, and make the public understand, what must be the difference in all the qualities that go to make government efficient and pure, between the men who will serve on the thousand and more small administrative bodies which it is proposed to constitute, and those who will compose the fifty or sixty assemblies regulating the counties of England.

The second advantage presented by large areas is the superior class of officials they are able to obtain. The wider the area, the more important the work and the higher the salary. Ambition and emolument alike attract to them the best men. In sanitary organisation this is of peculiar importance, for success depends chiefly on the qualities of the health-officer. Our Council have already published an earnest protest, which on their behalf I here repeat, against the idea of the Commissioners that duties requiring for their beneficial exercise much tact, prudence, matured judgment, and large experience, can, as a general rule, be safely intrusted to the inexperience of "young men entering on practice", by whom they would be discharged "only so long as they were acceptable, and then resigned to younger men, fresh from the schools". Such a proposition seems to imply a misconception, or rather a want of conception, as to the great science of preventive medicine, which, for the adequate mastery of its wide principles and multifarious details, requires the devotion of a life. An officer of health should be paid such a salary as will secure the services of trained intellect and high character; and, being thus remunerated, he should be rigorously debarred from private practice, not only that he may devote his whole time to the functions of his office, but that he may be free from personal influence in performing his duty. Such an officer can be obtained by counties, but seldom or never by unions. The rateable area of a county, supplemented as it would be by boroughs which would unite with it for sanitary, as they now do for gaol and police, purposes, can sustain a cost under which the union must break down.

It is urged, indeed, that every union has a medical officer, and it is proposed to place the sanitary welfare of the country in his hands. We protest against such a system. No one has a higher sense of the services and merits of a body of men, signally underpaid for their work, denied the social recognition of enrolling them in the civil service of the Crown, and struggling manfully, in the great majority of cases, though beset with difficulties, to do their duty to the poor. But I cannot believe that these meritorious officials possess the qualifications necessary for sanitary work. It is no blame to them that they have not been trained for duties which require, as our late colleague, Dr. Symonds of Bristol, pointed out, very different acquirements from those which are successful in the treatment of sickness; nor is it easy to see how professional men, whose time and energies are absorbed in daily toil, are to qualify themselves by that "study of all sanitary questions" which the Commissioners recommend as desirable for medical officers of health. Granting them even the necessary qualifications, these Poor-law practitioners are under the great disability of private practice. On that important point I will content myself with quoting from a valuable minute issued by the General Board of Health, dated December 20th, 1855, and signed by the Right Hon. William Cowper, President of the Board. The minute deals with the duties and qualifications of a medical officer of health, and says: "It will be well to debar him from the private practice of his profession; first, because the claims of such practice would be constantly adverse to those of his public appointment, the duties of which (especially at times of epidemic disease, when his official activity would be most needed) private practice could scarcely fail to interrupt and embarrass; secondly, because the personal relations of private practice might render it difficult for him to fulfil with impartiality his frequent functions of complainant; and thirdly, because, with a view to the cordial good-will and co-operation of his medical brethren, it is of paramount importance that the officer of health should not be their rival in practice, and that his opportunities of admonitory intercourse with sick families should not even be liable to abuse for the purposes of professional competition." Now, if this reasoning be sound—and much evidence has been collected both in our own country and on the Continent in its support—it follows that the Poor-law practitioners, who depend on private practice for their livelihood, are not fitted for the functions of health-officers. But I would not be supposed to argue that they may not be usefully employed in our sanitary organisation. I believe, on the contrary, that they could render valuable aid as subordinates, with some small increase to their present meagre remuneration, under a highly trained superior, such as a county administration would supply.

The third advantage derived from the adoption of large areas of administration would be the diminution of conflicting authorities, and of the delays and difficulties incident to the carrying out of joint works. It must be remembered that the boundaries of Poor-law unions were never adjusted with any view to sanitary purposes, and would frequently be found singularly ill-adapted for such works as drainage and water-supply.

It would be difficult to overrate the obstacles to an adequate administration which will be raised by the multiplicity of sanitary districts advocated by the Commissioners. In fact, I believe their scheme could never work except under one condition, viz.—that local government should be granted in form and denied in reality; that the central office should interfere in every detail, and be absolute over all authority. If such be the object, the plan proposed is logical enough; small areas can be easily "managed", and small men readily coerced; important bodies, on the other hand, are apt to hold their own. The question rests with the country. Centralisation is not popular, and it can hardly be made so by calling the machine of dictation a "Local Government Board." The true remedy for this and other perils is to make the government of counties more extensive and complete. It is objected that the present system is not representative; and though this is not accurate, since the governing assemblies are really representative of their districts in the highest sense of the word, yet the time has probably come when an elective element should be introduced into the administration. What is most needed is, that this should be done with the least possible disturbance of existing good. I believe that a far better plan than the creation of new "boards" would be found in the restoration, under forms adapted to modern life, of the ancient County Court. That tribunal, which came down to us, as to other nations of Europe, from those masters of organisation and government, the Romans of old, used to administer not only the civil and criminal justice, but the finance and government of every county. No one would propose to revive it in its antique fashion, when every freeholder attended its councils; but a system of representation, fairly divided between the existing authority, the justices, and the local taxpayers, might reassume all or most of its former powers. Such a body might be trusted to levy taxation on a more equitable basis than the present rude injustice of mulcting one kind of property for the benefit of all. It would take the charge of all roads, and would probably absorb the functions of the smaller boroughs. It would administer the sanitary laws, through competent officials, over an extent of territory adequate to their due execution, and with an authority which no extraneous office would venture to impugn. Such a body might well relieve the Imperial Parliament of a portion of that local bill business, such as gas and water supply, which now weighs down its energies; and in Ireland it would remove all legitimate grounds for "Home Rule" agitation. More than all, such bodies would perhaps be the best guarantee that the wit of man could devise for the perpetual preservation of liberties which may yet be endangered by anarchy. It is remarkable that the one country in Europe which has preserved in its entirety the ancient county organisation, is the one whose constitutional freedom has survived more disasters than any other. The history of the kingdom of Hungary, too little known to Englishmen, bears record of three periods when parliamentary government was submerged by war and despotism; and on each occasion it rose triumphant from the flood, because the national institutions were founded on local liberties which could not be rooted up. England has probably nothing to fear from individual tyranny; but, unless the signs of the times mislead us, there is much to be dreaded in the future from the despotism of the mob. The avowed aim of the revolution now meditated by the fanatics of disorder is to crush out individual freedom as much as to abolish proprietary rights. The best bulwark against such a foe will be found in the power and stability that are native to local institutions. The brawlings and corruption of unqualified democracy have sickened the world, and sound government, the final end of all legislation, is to be found only where property and education have weighted the scale in favour of order and honesty.

I have dwelt at some length on this question of sanitary organisation, not only on account of its intrinsic importance, affecting, as it does, in so large a degree the material prosperity of the people, but also because the report of our special committee on the subject has occupied much time and labour for months of this year. That document is before the public, and may be judged on its own merits; but I could not pass to another topic without acknowledging the services of Dr. Rumsey and Dr. Stewart. Nor can I refrain from expressing once more the sense entertained, I am sure, by the whole Council, of the value of the volumes compiled by the Royal Sanitary Commission. Should the legislation which must soon come go no farther than their recommendations, although I sincerely trust it may, a great stride will have been taken in the path of sanitary improvement.

# INTRODUCTORY LECTURE

TO

## THE COURSE OF CLINICAL OPHTHALMOLOGY AT ST. THOMAS'S HOSPITAL.

By R. LIEBREICH, M.D.,

Ophthalmic Surgeon and Lecturer to the Hospital.

GENTLEMEN,—Ophthalmology was formerly considered a subordinate branch of surgery. By its astonishing progress, however, during the last twenty years, it has risen to the rank of a separate science. The most eminent physiologists, surgeons, and physicians, have, by persevering study and attention, developed the science and practice of ophthalmology until they have given it a scientific independence. Special studies and special training have become a necessary consequence of its high development.

The treasurer, the governors, and the medical staff of this hospital and medical school have promptly recognised the importance of the subject. With the greatest care and liberality, the governors have fitted up a special department for the treatment of the diseases of the eye, and for instruction therein. The completeness of all the arrangements of this institution justly entitles us to indulge the pleasant expectation that it will not turn out inferior to similar departments of other general hospitals, nor even to any special eye infirmary.

I hope, gentlemen, you will be anxious to derive all possible benefit from those favourable circumstances. For some time, however, there will, no doubt, be some difficulties arising out of my incomplete command over the English language; but I trust they will soon be diminished. Indulgence on your part, and my best intentions, assisted by long experience in teaching, will speedily help us over these difficulties.

The teaching of ophthalmology aims at two widely different objects. The one is merely to give the student a concise view over this part of medicine, and to impart to him as much knowledge of the subject as every practitioner ought to have, whatever branch of medicine he may take up afterwards; the other purposes to educate ophthalmologists.

The relation of our department to this hospital and medical school requires that our principal attention should be directed to the first object—namely, to impart a general knowledge of the treatment of diseases of the eye. I hope, however, that those who may take special interest in this branch of study, and may intend devoting themselves entirely to it, will have every opportunity of doing so, and they will always find me ready to assist them in their pursuits. The laboratory attached to this department will afford them the means for original researches, and my ample pathological collection, which I have brought over from my *cliniques* in Paris, will give them material for microscopical investigations.

A systematic course will be given in the summer session. During the winter I purpose giving clinical lectures twice a week on cases in the out-patient department. On Mondays we will analyse cases of more medical interest, and practise the use of the ophthalmoscope; on Thursdays we will take surgical cases, and perform the necessary operations.

Now, before I enter into the nature, the course, and the treatment, of an individual case, I shall have to draw your attention to the best method of examining your patients. I shall first try to teach you what you ought to learn by looking at a patient before you ask him a single question—how to examine his eyes in ordinary daylight, how to examine them by lateral illumination, and how to use the ophthalmoscope.

In subsequent meetings we shall have to complete this by examination of the refraction, accommodation, acuteness of vision, field of vision, binocular vision, and so forth, for which we require answers from the patient to our questions. I shall bring before you first three patients—one we will examine together by ordinary daylight, a second by lateral illumination, the third by the ophthalmoscope.

In examining a patient in broad daylight, I warn you, before all, not to adhere to the wide-spread practice of taking hold simultaneously of both his eyelids and drawing them asunder, in order to see at once as large a surface as possible. It is, if done by one, already disagreeable for the patient; and it will certainly be insupportable if done by a larger number of students. But the chief bad consequence is, that the irritation produced by thus handling an inflamed eye increases the hyperemia, and gives an erroneous impression of the actual state. In inflamed and irritable eyes a similar mode may even prevent you from a successful examination. I advise you, therefore, first to look at this eye at a distance, and then close to it, without touching it, and then to observe the different parts of the surface of the eye by making the patient move the eyeball in the different directions—namely, upwards, downwards, to the left, to the right. During these examinations you

may gently draw alternately on the upper and on the lower eyelid; only, after having examined the surface of the eyeball in the way just described, you may then evert the eyelids, if necessary, in order to see their inner surface.

In the second patient, you will easily recognise in daylight a cataract of his left eye. But in order to distinctly recognise the nature, the consistency, the maturity of this cataract, it is necessary to examine him by lateral illumination. In a dark chamber, we will, by means of a convex lens of two inches focus, concentrate the luminous rays of a gas-flame, placed at the side of the patient, upon the point which we wish to examine. This method allows us to look through the anterior part of the crystalline lens, even if it be not perfectly transparent, to the nucleus, and even to the posterior surface.

After having shown you an instance of each of these three methods, I shall now treat more explicitly of lateral illumination. For a long time the illumination of eyes by means of a convex lens has been occasionally resorted to. But the idea of introducing it into practice, as a systematic method of examination, was conceived by myself after I had become acquainted with Helmholtz's treatise on "Accommodation." One of his experiments showed so clearly the substance of the cornea and the crystalline lens, that I concluded that it must equally well, if not better, show even the slightest cloudiness in the refracting media. The practical application verified my conclusion, and I then combined this method of illumination with a strong magnifying power, a pocket lens, and even a microscope. I finished the first communication I made, seventeen years ago, on this subject, with the following words:—"Such an intense illumination, directed upon a single point by means of a light which can be freely regulated, allows us the minutest investigations. The most practised observer could only in a very imperfect manner recognise, by the most attentive examination, in daylight, such details as the lateral illumination shows with the greatest facility and clearness."

Yet this very clearness is not without the danger, for an inexperienced observer, of overestimating the alterations so easily observed. Thus, for instance, one who for the first time sees, by dilated pupil and lateral illumination, a senile crystalline lens, may think it to be a cataract. The somewhat lessened degree of equal transparency which is proper to the crystalline lens of everybody in advanced age is sufficient to make its substance very distinctly appear of bluish-grey colour, even if it seem absolutely transparent by daylight, and by the ophthalmoscope. To get a correct idea of the effect of lateral illumination, let us compare it with a beam of sunlight entering a dark room through a hole in the shut window-blinds. In the bluish-grey stripe which indicates the passage of the luminous ray we can see even the finest particles of dust, and thereby recognise to what illusions common daylight leads us in regard to the purity of the air which we respire. In an analogous way, and even in analogous colour, the cornea, as well as the crystalline lens of the normal eye, are seen by lateral illumination. It is necessary, therefore, to begin observing normal eyes of the different periods of life before studying any pathological changes.

In observing the cornea, it is easy to combine lateral illumination with a strong magnifying power. Here, the slightest changes can be recognised with the greatest certainty. The different kinds of cloudiness which, by common daylight, appear of quite identical nature, are easily distinguished; and we are able to state whether they belong to the superficial or to the deeper layers of the cornea. Very extensive opacities in the cornea may prevent us from observing the iris and the pupillary region; but we can overcome this obstacle by concentrating the light upon the iris without illuminating the opacities of the cornea. Of the utility of this process, I shall show you to-day an example. In one patient, with extensive central cloudiness of both cornea, you will, by concentrating the light upon the crystalline lens, be able to see extensive opacities in the latter, if you look through the non-illuminated part of the cornea. This would be impossible by daylight.

Of the two convex lenses usually given with the small ophthalmoscope, you will do best to use the stronger one to illuminate the eye, the other to regard the illuminated part. You are holding the latter before your eye, and about one inch and a half to two inches before that of the patient. It will be better, however, to begin with simple illumination without any magnifying power. The cornea and pupillary region must be illuminated quite from the side, whilst the observer is looking from the opposite side. The equatorial part of the crystalline lens is also to be illuminated from the side, but it is to be observed nearly in the same direction. For the posterior pole of the crystalline lens, and the neighbouring parts of the vitreous body, it is necessary to have the light fall a little more from the front. Very different effects of illumination are obtained by somewhat approaching or removing the lens, by shifting it forwards or backwards, and by letting the light fall in a more or less oblique direction. By practice only you can learn how to profit in a special case by the variety of the luminous effects.

## TUBERCULOUS PHTHISIS.\*

By EDWARD LONG FOX, M.D., F.R.C.P.,

Physician to the Royal Infirmary, and Lecturer on Principles and Practice of Medicine in the School of Medicine, Bristol.

AMID the various opinions upon phthisis, it seems absolutely necessary to give up the idea of Laennec and Louis, that "tubercles in the lungs should be recognised as the anatomical character of phthisis". Further research and more accurate observation enable us now to class under the head of phthisis several tolerably well-known diseases, and especially those forms of chronic pneumonia which Dr. Addison described and figured beautifully long before Niemeyer published anything on the subject. But the questions which I would venture to propose for our consideration, are—How far are we to go in this direction? To what extent are these new views in accordance with the clinical experience of many of us? The data for discussion are contained in Niemeyer's monograph upon Phthisis, and would include the following propositions.

1. Chronic catarrhal pneumonia is one of the very commonest diseases, and is not particularly dangerous, under appropriate treatment.

2. The greatest danger to most phthisical patients (*i.e.*, those suffering from chronic catarrhal pneumonia) is the development of tubercles.

3. If there be only a few tubercles, they are almost exclusively found in the immediate neighbourhood of cavities or cheesy deposits; and they seldom, if ever, exist without there being found somewhere or other in the body cheesy deposits.

4. Tuberculosis is in most cases a secondary disease, originating in some way unknown to us in the action of cheesy morbid products on the organism.

5. The connection is probably a local influence, in which perhaps the lymphatics take a prominent part, rather than an infection of the blood.

Niemeyer's views seem to me to be too much confined to the lungs. Although I am very far from allowing Virchow's dictum to be true—*viz.*, that the lungs are the organs least often affected with tubercle—yet in the consideration of this subject it is necessary to look at the disease as it affects the whole system. General tuberculosis, as seen in young children, may affect almost every internal organ of the body. We see it complicated with, and perhaps dependent on, chronic disease of the ear; we see it often enough associated with cheesy bronchial or mesenteric glands; but I confidently appeal to the experience of all pathological observers, when I say that it is not unusual to meet with general tuberculosis without any glandular or inflammatory lesion that can have preceded the tuberculous growth in point of time. Even Niemeyer himself confesses that miliary tubercles are found without any pre-existing cheesy deposit or cavity, though in his opinion this occurs but seldom. I know that the growth of tubercle in many organs after the injection of various substances into the cellular tissue of guinea-pigs, as seen in the experiments of Dr. Wilson Fox and others, will be cited against the blood-view of this disease; but none of these experiments exclude the idea of septic influence, and thus they rather support the opposite of Niemeyer's dictum.

But if this condition of general tuberculosis can exist, say even once in a hundred times, without pre-existing cheesy deposit or other degenerative result of previous inflammatory action, there must be some other factor not recognised by the author of these new views, which may possibly at least influence the development of tubercle in all cases. Do we not learn something of this by studying the mode of death in these victims of tubercle? I do not speak of cases in which the lungs are enormously implicated, and much of the pulmonary substance rendered useless, or of those in which exhausting diarrhoea with intestinal ulcerations may have hastened the fatal event. But what do we constantly see? a patient ill for two or three weeks with symptoms simulating enteric fever or acute pneumonia, and no *post mortem* appearance, save lungs studded with miliary tubercle, but otherwise healthy. It is not from interference with the pulmonary function that such a patient dies. Collect all the tubercles together, and they would not take up the space of half a lobe of one lung—and we know with what amount of lung-spoiling a man may live for years. It is not even from the high fever (bad as that is) that death ensues—for in these cases the temperature often manifests the most startling remissions; it is from the condition of the blood, hopelessly unfit for any of the functions of the body. The man dies, just as one dies in the first week of typhus or variola, before any lesion of the internal organs can be recognised. Take, again, tubercular meningitis. The lungs may be scarcely affected; the lesion of the

meninges so slight that it requires a practised eye to realise it: nay, even in some cases death ensues with headache, convulsions, strabismus, that terrible specific cry, etc., and without any lymph being poured out even over the base of the brain, and without any tubercle on the vessels. To what does such a case succumb? Clearly not to pressure on the brain; clearly not to lesion of any organ. Death must depend on the condition of the blood itself. Similar facts occur to us in connection with tubercle on the peritoneum and pleura.

It is useless to talk to us of special vulnerability of such patients if there be no wound of tissue or organ to be found; but inherent tendency to tubercle, irrespective of all preceding inflammation, is intelligible, and, I believe, in accordance with daily experience.

Let us turn for a moment to chronic bronchopneumonia. It is idle to object to this disease being a true pneumonia because of its occurrence at the apices of the lungs, or because its primary symptoms differ from what we meet with in acute inflammation of the parenchyma of the lung, or because the physical signs are not the same. Bronchopneumonia is much more rich in cell-growth than acute parenchymatous pneumonia. In the latter, the air-cells are filled with an exudation much more rich in fibrine. Acute bronchopneumonia is just as likely to affect the apices of the lungs as the bases, as is often seen in croup and whooping-cough. But between ordinary acute bronchopneumonia and that chronic form that results in phthisis, there are what seem to me specific differences, apart from the question of duration of the disease. The acute form is singularly amenable to treatment; the chronic can be by treatment rendered inert for years, but is scarcely ever cured. The acute form is generally unilateral; the chronic, in a large number of cases, bilateral; the acute form never, so far as is known, hereditary; the chronic not seldom hereditary. These points go some way to show that the latter disease is not merely accidental, but that it depends on some constitutional condition. And when, in addition to this, we find after death miliary tubercle profusely scattered over the portions of both lungs that are unaffected by the original disease, or attacking the pleura or the peritoneum, it is more reasonable to believe that it is a manifestation of constitutional disease rather than a consequence of the previous inflammation.

The very incurability of the disease points, I think, to its constitutional origin. How often do we see the consolidated spots in one and often in both lungs remain in the same condition for many years. Now, under Niemeyer's view, there surely is no need that a large surface of the lung should be so consolidated for infection of the system to take place. The smallest spot of disease would act equally well. But if the disease be of small compass it will remain inert, under suitable treatment, for a whole life. I have lately seen a lung *post mortem*, in which, from the history of the case, we were sure that the small portion of lung affected had become consolidated thirty-five years before. Certainly, in the face of facts like these, if Niemeyer be right at all, that tuberculosis originates in the action of morbid products on the organism, it is indeed, as he says, in some way unknown to us.

Take another instance. There are instances—unhappily too frequent—in which every member of a family becomes phthisical at a certain age. It is not unusual to see large families with one or both parents phthisical, and almost every member of the family will die of phthisis before twenty-one. In a case lately under my care, and in which no tubercle could be detected, although the right lung was everywhere riddled with cavities, there was a strong family history of phthisis, four sisters having died of it.

Niemeyer says that pneumonia, resulting in cheesy infiltration, occurs chiefly in delicate badly nourished persons. This experience is partly founded on the great vulnerability of such persons, and partly on the fact that the inflammatory nutritive changes occurring in them show a tendency to an abundant production of cells, and thereby to a cheesy metamorphosis of the inflammatory products; and that pneumonia of this character does not usually occur, even in delicate and vulnerable persons, before the age at which pulmonary diseases generally become more frequent, and it then takes the place of those inflammatory diseases of other organs which have prevailed during the preceding period of life: and he would also say that, although it is not proved that tuberculosis is an inheritable disease, yet an inherited disposition to pulmonary phthisis may exist; *i.e.*, a weakness or vulnerability of constitution, which in the parents has already been either the cause of pulmonary phthisis, or has only been developed in them by the disease. Now this seems to me to be forcing facts to suit his theory. Clinical experience demands an explanation of the close relation between scrofula and phthisis, considering how large a number of phthisical persons have suffered from glandular swellings in early youth, from which they have entirely recovered, and after death we find in them no caseous degeneration of either cervical, bronchial, or mesenteric glands. So our author falls back upon this delicacy of constitution imparting

\* Prepared for the Medical Section of the Annual Meeting of the British Medical Association at Plymouth, August 1871.

a vulnerability; i.e., increasing the chances of having pneumonia, leaving out of sight—in fact, denying—what seems to be a much more reasonable explanation of the phenomena—viz., that the phthisis is only another manifestation of the same constitutional diseased condition; for we question that the great tendency to pulmonary disease exists more specially at puberty than during childhood. The age at which pulmonary phthisis is most prevalent and most fatal is certainly not the age at which patients are particularly liable to other morbid conditions of the lungs. It would be more in accordance with medical experience to say that childhood showed a greater liability to diseases of the lungs; and, if so, then, according to Niemeyer, the age most liable to pulmonary disease shows tuberculous disease in other parts of the body more frequently than in the lungs.

Take the case of gout. It is a fairly recognised fact that we may inherit gout—and not only so, but that we may inherit it from a grand-parent, although the parents may have shown no manifestation of it. But at what age does gout manifest itself? Certainly not, as a rule, at all ages of life; much more frequently at or after middle life. We do not say that such a person inherits a vulnerability; we say that he inherits a constitutional taint, that manifests itself most usually at late periods of life, probably because then the system is weaker, repair more difficult, the mode of life more conducive to that partial and insufficient metamorphosis which seems to act as the exciting cause of this disease. Is not the fact that phthisis often does not attack its victim until the age of puberty to be explained in a similar way? It is a matter of common observation that childhood is the age for general tuberculosis, tuberculous meningitis, and tubercle of the peritoneum; that puberty is the period most liable to tubercle associated with pneumonia; and that acute miliary tubercle of the lungs is about equally to be found at puberty and between the ages of twenty and forty. But that a constitutional taint should be inherited and manifest no special phenomena until the age of seventeen, and then attack the patient with all possible virulence, is only analogous to what we see in other diseases universally recognised as transmissible from parents to children.

Does clinical observation throw any light on this subject? Certainly the stethoscope does not help us. The physical signs, as gathered by auscultation and percussion, are pretty much the same in tuberculous and non-tuberculous phthisis; or at least, excluding acute tubercle (in which disease the physical signs are mainly negative), the breaking down of lung associated with tubercle, and a similar condition without tubercle, cannot be distinguished by means of the stethoscope. The flattening of the chest may exist with both; the emaciation, the rapid pulse, the hurried breathing, the perspiration, the curved nails, the dyspepsia, and the diarrhoea. Albuminuria, which is often found in acute tubercle, is absent in these other conditions, unless the patients have renal disease unconnected with the pulmonary mischief. The chlorides are never, or scarcely ever, diminished in either disease; indeed, although constantly examining this point, I never but once found any diminution of the chlorides in the urine, though possibly this experience may be due to the fact that the majority of cases come under notice long after their commencement.

Is there any help to be got from the thermometer? Wunderlich says that it is impossible by means of the thermometer to distinguish tuberculous from non-tuberculous phthisis, and it is not easy to express a different opinion, considering his long and careful observations upon temperature. Still, in the progress of these cases, there does seem to me to be a difference in temperature. In the chronic pneumonia of the non-tuberculous subject, the temperature will stand between 100 deg. and 103 deg. Fahr., not necessarily higher in the evening than the morning—indeed, not unfrequently higher in the morning than the evening, but keeping regularly about these points without sudden and irregular remissions. It may also, under suitable treatment, reach the normal point and remain quiet for a considerable time, or can be entirely recovered from any recurrence of the progress of the disease, however, being manifested by an exacerbation of temperature. But the case is somewhat different in tuberculous phthisis. Niemeyer says, "We have not yet arrived at definite conclusions in our investigation of the hectic fever of phthisical patients, especially concerning the causes by which its regular courses are disturbed. But we can already say this much, that in tuberculous phthisis in the restricted sense, and when tuberculous complicates a destructive pneumonia, the differences between morning and evening temperatures are as a rule much smaller. We give, therefore, *causa parva*, a more favourable prognosis as long as the pyrexia has the character of a febrile remittens, with almost intermittent type, than when it approaches to that of a febrile continua."

Now this is only very partially correct. The height to which the temperature ascends is often in excess of what is seen in chronic pneumonia; but, as has often been said, the temperature in tuberculous phthisis is as irregular as in typhoid fever it is regular. Any one who pays at-

tention to this point will find how often and yet how irregularly the temperature will fall from 104 deg. or 105 deg. Fahr.—five, six, and even eight degrees Fahr., to rise again in the course of a few hours. Except in certain examples of pyæmia, the intensity and irregularity of these remissions will be found in no other morbid conditions, and in certain cases of obscurity they will prove of diagnostic value. The marked difference between this irregularity of tubercle and the comparatively regular remissions of non-tuberculous phthisis will prove useful in the determination of the special form of disease we may have before us, and affords an illustration of the truth of an idea, sometimes lost sight of, that nosological distinctions must be drawn not only from minute microscopical alterations of structure, as seen *post mortem*, but from such appearances plus the clinical phenomena during the life of the patient.

We would sum up the basis for discussion thus.

1. There are several forms of disease included under the head of phthisis.

2. Tubercle, whether of the lungs or of other organs, is due to a constitutional disease; and this is shewn by death occurring without *post mortem* results sufficient to have caused it.

3. Tubercle often exists quite independently of caseous deposits or vomicae.

4. This morbid condition is inheritable, but may be developed *de novo* by debilitating influences.

5. Its possible manifestations at all ages, and its frequent non-manifestation until the age of puberty, is only analogous to what is seen in other constitutional and inheritable diseases.

6. Chronic pneumonia found associated with miliary tubercle is not connected with it as cause with effect. The tubercle only becomes developed in cases in which the patient has previously had the tuberculous taint of constitution.

7. Some fatal chronic pneumonias may owe their irremediable properties to the same constitutional weakness, even where no miliary tubercle is discovered after death.

8. In general, non-tuberculous phthisis can be distinguished from tuberculous by clinical phenomena, and especially by the use of the thermometer.

#### ON PUNCTURES OF THE COLON FOR THE RELIEF OF TYMPANITES.\*

By J. HANCOCKE WATHEN, L.R.C.P.Ed., M.R.C.S.Eng., etc., Fishguard.

THE case which forms the basis of this paper has already been recorded in the columns of the *Practitioner* for October last. My object in again bringing it forward is to elicit an expression of opinion on the propriety of resorting to puncture in those distressing cases where other means have failed to relieve the tympanites. Having read in the *Practitioner* for February, 1869, the notes of a case of obstruction of the bowels under the care of Dr. Clifford Allbutt of Leeds, in which the distension was so great that Mr. Teale, whose assistance was obtained, punctured the colon, I determined to adopt such a procedure in the first suitable case that presented itself. Such an one came under treatment in a few days. On the 13th of the same month my father, Mr. Wathen, was requested to visit Mrs. G., aged 29, who had, half an hour previously, while engaged in some domestic duties, been suddenly seized with most severe lancinating pain in the lower part of the abdomen. She was cold and collapsed, presenting the appearance of one suffering from severe shock. The patient supposed herself to be about six weeks gone in pregnancy, and stated that in her previous pregnancies she had experienced pain and faintness about this period. Acute peritonites soon declared itself. This, under full and frequent doses of opium, turpentine stupes, etc., was considerably subdued; but the abdomen became intensely tympanitic. We failed to afford any relief, although free fecal evacuations were procured by turpentine and castor-oil enemata, administered by an O'Beirne's tube. The distension increased, causing great distress, accompanied by vomiting. I advocated puncture of the bowel, but could not obtain consent until the evening of the third day, when the patient earnestly requested relief by operation. After consulting with Mr. Brown of Haverfordwest and Mr. Wathen, I first plunged a small hydrocele trocar and cannula into the transverse colon, then into the descending, and lastly over the ascending colon. As soon as the force of the current of gas lessened, the cannula was withdrawn and reintroduced, being guided by the most prominent portion of the colon. The first two punctures emitted gas with sufficient force to blow a candle out when held near the cannula;

\* Read at the annual meeting of the South Wales and Monmouthshire Branch.

but, through the puncture over the ascending colon, no gas escaped—to be accounted for, I think, by the fact that the colon was emptied, and, not offering sufficient resistance to the trocar, was pushed in front of it. The abdomen was very considerably diminished in size; the patient expressed herself as being much relieved, and appeared grateful for this diminution of her sufferings. The immediate object—viz., relief—was obtained; and I think that, had this simple and painless operation been performed earlier, it would certainly not, to say the least, have had any prejudicial influence on the case. The patient became more exhausted, and sank next morning. No *post mortem* examination could be obtained.

As far as I can ascertain, abdominal puncture for the relief of tympanites has been performed in five other cases, to which I would briefly draw your attention. The first case is the one already referred to, which occurred in the Leeds Infirmary. Mr. Teale punctured the colon in the transverse and descending portions with the best results as regards the intestinal mischief; the obstruction being completely overcome, and the patient, who had not passed either flatus or motion for many days, freely voided both. Unfortunately, the patient was also suffering from secondary double pneumonia, to which he eventually succumbed. At the autopsy, "no traces of the punctures could be detected, except upon the outside of the body; no air had escaped into the peritoneal cavity". The second case is one recorded by Dr. Davey of North-woods, Bristol, in the JOURNAL for August 21st, 1870. The patient was a little girl aged nine years, whose abdomen was punctured by Mr. Salmon of Thornbury, for an intense tympanites, accompanying tubercular peritonitis. The patient lived twelve days after the puncture, which, Mr. Salmon states, "gave great relief, and tended much to mitigate her sufferings, previously to which the difficulty of breathing had been most distressing." The *post mortem* examination showed that the puncture had in no way hastened the end.

Dr. Davey refers to two cases of intestinal puncture performed under the advice of Dr. Fossagrives of Toulouse. In the first case, the patient "was perfectly cyanosed and suffocating; an exploring trocar was inserted into the most distended part of the lower umbilical region. Two fresh punctures were made next day, and gave so much relief that the patient's life was prolonged four days". In the second case, six punctures were successively made and the patient cured.

The last case to which I have to refer is one that occurred in the practice of my friend, Staff-Surgeon J. R. Thomas, while on the West Coast of Africa. The patient, an American, was suffering from chronic dysentery, accompanied with gradually increasing tympanites, until he became so much distended as to implore for relief by any means possible. Puncture of the transverse and ascending colon was practised with the best result; but, unfortunately, a few days afterwards the patient, who had been up and about, went in for a heavy debauch, had a relapse, and eventually succumbed.

You are all no doubt well aware that puncture of the intestine has long been practised on the lower animals. The manner in which the operation is usually demanded is thus. A herd of cattle is turned into rich clover or grass; some of them, unless great care be taken, become gorged on the luscious vegetation; rapid fermentation takes place, which results in great distension by gas; the animal drops, and, unless relief be promptly afforded, soon dies.

The treatment is simple, and well known to most graziers. A puncture is made into the most prominent point in the flank with any sharp instrument at hand—generally a pocket-penknife. I have just been informed by a most intelligent farmer that he has repeatedly performed the operation, always with the best results, never having lost a case. In the case of one calf he has punctured as many as twelve or fourteen times, and has occasionally done it with an ordinary butcher's-knife.

I must confess that the results obtained in the lower animals are more favourable than those in the six cases I have quoted as happening in the human subject; but one must recollect that puncture has only been resorted to after all other means have failed, thereby losing much valuable time, and generally in those cases having a fatal tendency. On reviewing the evidence afforded by *post mortem* examination, I cannot conceive any real objection that can be urged against the operation, as not a trace even of the punctures could be detected in some of the cases, and in none had there been anything found which would contraindicate it. When I picture to myself the immense distress and suffering present in an intensely tympanitic patient, whatever may be its cause, and then recall to mind the ease and quiet, if not anything more, which we are enabled to afford our patient by what I am bound to describe as a simple, harmless, and painless operation, I feel drawn to the conclusion that it is a proceeding not only justifiable, but urgently demanded at our hands.

If this paper be the means of obtaining a more extended trial of the operation, my object in reading it will be entirely gained.

## CASE OF HÆMORRHAGIC SMALL-POX: WITH CLINICAL REMARKS.

By ROBERT GRIEVE, M.D., Medical Superintendent of the Hampstead Hospital.

THE following notes of the case were made by Mr. Bland, Assistant Medical Officer.

T. I., aged 27, a cabman, was admitted to the Hospital late on the evening of the 9th of October. He had two vaccination-marks. He had been ill for six days. The eruption was copious and in the papular stage, and of a dark purple hue.

October 10th. In the morning, he had severe epistaxis and hæmoptysis. His tongue was dry and brown; his bowels were confined. He had passed a good night. He took very little food. Pulse 120; temp. 105 deg. He was ordered to have ten minims of tincture of sesquichloride of iron in half-an-ounce of water every four hours; with ice, beef-tea, and milk *ad libitum*.

October 11th. He had now epistaxis, hæmoptysis, melæna, and hæmaturia. There was great ecchymosis of the eyelids and effusion of dark-coloured blood beneath the ocular conjunctiva. He took food more freely. His breathing was laboured. Pulse 130; temp. 105 deg.; respirations 28.

October 12th. The hæmorrhages continued. There was ecchymosis of the whole of the skin. The patient was much worse. Pulse 128; temp. 105 degs.; respirations 28.

October 13th. He had had slight delirium all night. He took large quantities of milk and beef-tea. Pulse 104; temp. 104 degs.; respiration feeble. At 3 P.M. he became quite unconscious, and continued in this state until his death, which took place at 9.20 A.M. on the 14th.

*Post mortem* examination thirty hours after death. The body was well developed and nourished. Rigor mortis was well marked. The eruption was confluent on the face, copious on the trunk and extremities. It was in the vesicular stage; the contents of the vesicles on the abdomen and lower extremities were purple, the areola not fading on pressure. The left pleura was adherent throughout with old adhesions; the right was much injected and ecchymosed, but there was no lymph or effusion. The right lung was dark and heavy, breaking down easily. Much black blood could be squeezed out, but there was no consolidation. Through the substance of the left lung were scattered masses varying in size from a bean to a walnut, which were red, solid, and granular, and sank in water. This lung was otherwise in the same state as the right. The left ventricle was moderately firmly contracted. The valves and orifices were healthy. The pericardium had a few spots of ecchymosis. The liver was softer and paler than natural. The spleen was dark and moderately firm. The kidneys had slight venous congestion.

One of the most noteworthy features in connection with the small-pox epidemic of 1870 and 1871 has been the large proportion of cases of the hæmorrhagic type which have occurred. In the Hampstead Hospital alone, over 400 instances of this form of the disease have been under notice since the 1st of December, 1870. Unfortunately, recovery from variola hæmorrhagica when well marked is rare indeed, and a specific for this terrible disorder has still to be found. Vaccination does not prove a preventive; the majority of the cases here had marks of some kind of previous vaccination. Certain occupations predispose to this type of the disease; thus, amongst males, engine-drivers and stokers, and in females, cooks and kitchenmaids, and others exposed to great heats, suffer severely. Above all these causes is to be placed a dissipated or irregular mode of life. Hæmorrhagic small-pox is very rare in childhood; but occasional instances are to be met with.

There is great variety both in the extent of the subcuticular effusions and also in the amount or seat of the active hæmorrhages. Sometimes the effusions are limited to small purpuric spots situated principally on the trunk and lower extremities; sometimes there are huge patches of ecchymosis here and there over the entire surface, as in the case of T. I.; but one symptom, which is almost constant enough to be called invariable, is the effusion under the conjunctiva, which is sometimes so great as to cause the membranes to bulge out, making the cornea seem a depression instead of an elevation, and giving a peculiar and characteristic look to the patient. Among the hæmorrhages, bleeding from the buccal mucous membrane is the most constant, except in women, when vaginal hæmorrhage is invariable. Then comes epistaxis; much more rarely hæmaturia; and, most rare of all, bleeding from the bowels. The case narrated above presents the peculiarity of having concurrently all these forms of hæmorrhage. The eruption appears and goes through the different stages more slowly than in ordinary small-pox. It rarely reaches the pustular form, and the vesicles are filled with bloody serum in place of the usual secretion. It is very

rare indeed to see the bold flat-headed pustule in the hæmorrhagic small-pox. In the case above related, on the eleventh day the eruption was still in the vesicular stage.

The patients emit a peculiar foetid odour, very different indeed from the characteristic smell of ordinary small-pox: it conveys the impression of putridity, and is consequently more disgusting.

T. I. had only slight delirium, which did not come on until within thirty-six hours of his death; and this will be found to be the history of a large proportion of the hæmorrhagic cases. Delirium as a rule does not occur at so early a stage of the disease, and is not so violent in its character, as in ordinary small-pox; and is usually the immediate precursor of a fatal result.

Patients take nourishment freely during the whole course of the disease, if we except those cases where, in the earlier stages, there is much swelling of the fauces and consequently difficulty of swallowing.

The temperature and the pulse, and I may add the respiration, do not seem to bear any fixed ratio to one another, but in almost every case vary to a great extent. As a guide to prognosis, most reliance is to be placed on the indications shown by the last named—namely, the respiration. In this individual, the temperature ranged high for a hæmorrhagic case; but, as usually happens, death was preceded by a decrease. In small-pox, 105.6 deg. may be taken as the limit of safety; but we have had many cases of fatal hæmorrhagic small-pox where the temperature at any stage after the appearance of the eruption has never exceeded 102 deg. As we never get any patients in the hospital till after the appearance of the eruption, I can only speak as to the subsequent stages. The range of temperature in hæmorrhagic cases is decidedly lower than in regular unmodified small-pox. In this form of the disease, the use of the thermometer as a help towards prognosis becomes of secondary importance, as we have other and visible symptoms which are to be relied upon. As mentioned above, the respiration is a safer guide to prognosis than either the temperature or the pulse; and this, in my opinion, applies to every form of small-pox. A steady increase from day to day in the number of the respirations is a most unfavourable sign.

The *post mortem* appearances found are those characteristic of the hæmorrhagic form of variola, if we except the old standing pleurisy. We have the ecchymosis extending to the serous surfaces; we have the engorgement of the lungs—in most instances, the immediate cause of death. The kidneys merely showed venous congestion; but, in other autopsies of similar cases, clots have been found in the pelvis of one or both kidneys. In this case, the bowels were examined; but, owing to the quantity of iron taken, were so discoloured that no opinion could be given on their state.

And now, lastly—and I am afraid with truth it may be said leastly—comes the treatment, which with T. I. was what for some time has been usual in this hospital—namely, small doses of tincture of sesquichloride of iron, and a free administration of ice and bland nutritive fluids. The iron seems in some degree to control the hæmorrhage, and acts as a general tonic. Whether it permanently affects the issue, is more difficult to say. But one thing to be learnt is, if we can do no good, let us avoid doing harm; and I believe that the administration of stimulants in variola hæmorrhagica does positive injury. The capillaries are evidently in such a state that the slightest pressure, either from external or internal sources, causes their disruption. If the heart's action be stimulated, the weakened capillaries of the lung give way, reducing that organ to a pulpy mass, rendering it totally unfit to perform its function, and hurrying on the fatal result, which in any case, perhaps, is inevitable. Although not believing stimulants to be so injurious in other forms as in the hæmorrhagic, I take this opportunity of entering a protest against their indiscriminate use in small-pox. In this disease, the dermatitis plays a more important part than that with which it is sometimes credited. The most common and fatal complications are those which occur with any extensive inflammation of the skin, such as scalds and burns; and I cannot but believe that stimulation will hasten the advent of congestion of internal and vital organs—a result much to be dreaded.

## EXPERIMENTS ON SANTONIN.

By ROBERT FARQUHARSON, M.D. Edin.,

Late Medical Officer to Rugby School, etc.

THE subject of santonin is both interesting and obscure, and I should be glad of permission to add my experience to the interesting remarks published by Dr. David Page in the BRITISH MEDICAL JOURNAL for September 16th.

About two years ago I was consulted in the case of a little boy on

whom a great variety of treatment had been unsuccessfully applied for the removal of thread-worms. Five grains of santonin were ordered at bedtime; and on my next visit I found the whole establishment in consternation at the effect of the remedy, which had caused a very copious and involuntary discharge of urine towards early morning. Such an accident was naturally most distressing to a boy of twelve, and pupil in a large private school; and more particularly so, as no consolation was afforded by any beneficial action on the disease for which the drug was prescribed.

Shortly afterwards I instituted a series of experiments on myself, and briefly append the results under the following heads.

1. *Effect on Vision.*—Twenty minutes after swallowing five grains, I observed flames to assume a decidedly yellow colour, as though spirits were being burnt. Ordinary white gas globes became deeply tinted with yellowish green, and writing-paper presented the same phenomena in somewhat less marked degree. During three hours the tints gradually increased, after which they faded by slow stages, until vision was restored to its normal standard.

The precise conditions under which these singular results take place, and the exact alterations of colour observed, have been submitted to most exhaustive study by a German physiologist, whose name I cannot now recall. *Post mortem* examination proves that a true staining of the retina is rapidly produced, but it is not probable that this can be detected during life by the ophthalmoscope. This opinion I base on the authority of an eminent oculist, and on the fact that, in the somewhat parallel group of cases where yellow vision attends jaundice, I have been unable to discover any unnatural appearance on careful inspection of the fundus of the eye.

2. *Effects on the Urinary Organs.*—Five grains were taken at bedtime, and next morning an irresistible and almost uncontrollable desire to micturate was felt, the act being attended with some irritation and smarting. The urine was of a deep saffron yellow, staining the pot and linen precisely as bile. It was of specific gravity 1.028. The quantity was decidedly increased, and the urea was somewhat in excess. The diuretic action continued during the day; and it was not until 8 o'clock P.M. that the secretion was quite free from foreign pigment.

3. *Effects on the Digestive Organs, and General Symptoms.*—Nausea and dryness of tongue were generally present; and on one occasion, after a ten-grain dose, well-marked tenesmus was experienced both by myself and by a friend who shared the experiment. After five grains, sleep was generally disturbed, and I usually woke unrefreshed, with sickness, frontal headache, and deficient appetite. But the best marked symptom, and one which I have not hitherto seen described, was a feeling of profound and most unusual depression, accompanied by so much irresolution and want of confidence in my own powers, as to render me quite unfit for work of any kind. This invariably followed even a single five-grain dose; and, beginning with dulness and heaviness, ran on into very much that sort of melancholia which I imagine jaundice sometimes produces. This denotes an effect on the nervous system which ought not to be overlooked; and, should further investigation prove its occurrence to be constant, and not to depend on any peculiar idiosyncrasy of my own, we may yet find in santonin an agent of some value in the almost unexplored regions of mental therapeutics.

## SULPHATE OF IRON AS A LOCAL APPLICATION IN PHLEGMASIA DOLENS.\*

By R. W. CRIGHTON, M.D.,

Physician to the Tavistock Dispensary.

I WAS first induced many years ago to employ this remedy in phlegmasia dolens, chiefly on the recommendation of Velpeau, who reported great success from its use in cases of erysipelas. Every one who has seen much of phlegmasia dolens, especially that form of it in which the pain and swelling commence at the calf of the leg and extend upwards to the groin, knows the tedious and painful course of such cases, and their not rarely fatal termination. Believing that the treatment which I now recommend is much more effectual than that usually employed—viz., leeching and ordinary hot fomentations—I venture to ask those who may not have previously used it in these circumstances to give it a fair trial.

In recent cases, it is best employed in the form of lotion (twenty to thirty grains to an ounce of water), applied as hot as the patient can comfortably bear it. Much trouble is avoided, and the constant

\* Read in the Midwifery Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

saturation of the skin with the lotion secured, by using spongio-piline, fastened loosely by tapes round the limb.

All the cases which I have so treated—five or six in number—have made good and rapid recoveries; and in one only, which was not seen for several days after the disease commenced, was there any great amount of hardness left in the superficial venous trunks at the end of ten or twelve days. In this case, the application of equal parts of belladonna and iodide of potassium ointments was effectual in dispersing it. In all the cases, after the bowels had been freely acted on, the muriated tincture of iron, either alone or combined with quinine, was given internally.

The rapid introduction of waste material into the blood during the puerperal state affords, I believe, some explanation of the action of sulphate of iron externally, and of the muriated tincture internally, in cases of phlegmasia dolens.

Arnott (*Med.-Chir. Trans.*, vol. xv, "On the Effects of Inflammation on Veins") has shown that, in inflammation of veins, the changes begin in the connective tissue towards the *outer part* of the vessel; and this even when irritant bodies are introduced into the cavity of the vein itself. The application, therefore, to the immediate proximity of the coats of an inflamed vein, which it cannot fail to reach either by absorption or imbibition, of an agent which is known to control vascular dilatation in erysipelas and other allied forms of inflammation, seems a rational method of treatment; while the antiseptic effects of the remedies, both external and internal, are doubtless of great importance.

Whatever the true explanation may be, I venture to hope that the use of sulphate of iron locally in phlegmasia dolens, and possibly in other cases of phlebitis, may prove a valuable addition to the means of treatment at present employed in these affections.\*

### SHOULD EVISCERATION EVER BE PERFORMED IN ARM-PRESENTATIONS?

By F. W. WRIGHT, Esq., Derby,  
Late Surgeon to the Birmingham Lying-in Hospital.

DECAPITATION *versus* evisceration in arm-presentations is a subject not without either interest or importance. Churchill says that, should ordinary measures fail "and version be impracticable, we must open the chest of the child and eviscerate;" and Dr. Collins condemns decapitation. Dr. Barnes, it would appear, gives the preference to evisceration; for he says that—"Sometimes perforation and evisceration are insufficient in themselves, and another step will be necessary in order to complete delivery. This ultimate step is decapitation." On the other hand, Dr. Davis makes this important statement: "It ought to be an established rule in practice, to decapitate in arm-presentations not admitting of the safer performance of turning." Perforation and picking out the viscera of the foetus is an operation so complicated and prolonged, and so abominable in detail, that it is matter of surprise how it comes to be advocated as preferable to the much more simple, much less disgusting, and much speedier operation of decapitation.

I propose the following as a simple and ready method of bisecting the foetus *in utero* in an arm-presentation, in which, from early evacuation of the liquor amnii, version is impracticable. The presenting member is to be seized with the right hand, and, while considerable traction is employed, the left hand is to be passed into the vagina as far as the shoulder-joint of the presenting arm, and thence to the neck of the foetus. The exact position of the neck having been determined, the left hand must be kept firmly upon it. A blunt hook, with a curve sufficiently large to embrace the neck, and having a perforation at the extremity of the curve, is armed with a piece of tape, and taken in the right hand; and the left hand being still in the vagina as a guide, the hook is passed over the neck and made thoroughly to embrace it, the tape which it carries being seized on the opposite side. The neck being now secured, to the end of the tape should be tied a leash of about a dozen very thin wires a yard long, twisted together at the ends. By pulling at the tape it will be drawn out of the vagina, and the wires attached to it will be drawn over the child's neck. By pulling these wires backwards and forwards with a saw-like motion, the head may be cut off in five seconds. The body may now be extracted by the

\* As an illustration of the efficacy of a remedy applied externally, may be mentioned that of a strong infusion of digitalis in ascites. Dr. Christison (*Monthly Journal of Medicine*, October 1850) gives several cases where the drug so applied to the abdomen completely removed the dropsy, after the same remedy with many others had failed when given internally. He also found it useful when applied to the limbs in cases of dropsy in Bright's disease. I have frequently used a strong infusion of digitalis (one ounce of powdered leaves to twenty ounces of boiling water) in similar cases, externally, with remarkably good results.

protruding arm; or if, as has happened to myself, it have been necessary to amputate the arm at the shoulder-joint to give room, the body may be readily removed by the crotchet hooked over the clavicle or one of the ribs. The head has now to be removed, and obstetricians are eloquent upon the difficulties which this part of the operation presents. But what can be more simple if the rule be observed, *decapitate close to the shoulders*? The head should then be firmly fixed on the pelvic brim by pressure on the abdomen from the hands of an assistant. A pair of strong forceps, somewhat resembling craniotomy-forceps, but with horrent teeth on the inner aspect of both blades, should then be made to seize the whole length of the neck which remains attached to the head, and traction made upon it until the head escape. I am confident that those who adopt this method will never again have recourse to evisceration.

### CASE OF RUPTURE OF THE UTERUS.

By GEORGE CLEMENTS, Esq.,  
Senior Surgeon to the Chorlton Union Hospital, Manchester.

E. E., aged 38, married, was admitted on August 25th, 1870. The patient, who was much emaciated, was in a state of extreme exhaustion, almost approaching collapse; the surface of the body being cold and clammy. The tongue was dry and parched; the lips and teeth densely covered with black sordes. The countenance was pale and haggard; while the expression revealed the fact that she was suffering intense pain. The pulse was small, rapid, and feeble; the respiration being hurried, difficult, and almost entirely thoracic. She complained of constant unceasing pain all over her belly; and, on inspection, the abdomen was found extremely distended. The tenderness, on the least pressure being applied to any part of the abdominal wall, was excruciating; and so great was the suffering thereby caused, that the patient refused to allow further examination to be made. It was ascertained, however, that the greatest pain existed in the left iliac fossa. There were tympanitis, and constant vomiting of dark greenish fluid. She was only comparatively easy when on her back, with her knees well drawn up.

On a vaginal examination being made, a very copious discharge of a thick, grumous, offensive character, was found freely escaping from the vagina. The os uteri was firmly contracted and closed, so that no presentation could be detected. The stethoscope was applied over the region of the womb, but neither foetal heart nor placental *bruit* could be heard. The patient could not pass urine without the aid of the catheter, and her stools came involuntarily under her.

She was the mother of four children, and stated that her confinements had been in every way natural, and unattended by difficulties. The circumstances connected with her domestic life had necessitated her working very hard to maintain her family, and this she did by taking in washing. But, after all, she had been living on in a wretched state of poverty and dirt, half starved and over-worked.

A day or two previously to her admission, and within a short period of the time when she expected to be confined, when lifting a heavy bucket of water, she felt of a sudden intense pain in the left side of her abdomen; it was much increased by her standing on a chair, and attempting to hang up the garments to dry. From this time, she took to her bed.

There is no evidence to prove that labour had commenced, for she stated, on admission, she had experienced "no pains" previously to her sudden illness; and the condition of the os uteri testified to the same fact. The rupture must therefore, in all probability, have taken place while she was lifting the heavy bucket, when she first complained of the intense pain. She remained at home three days; when, finding herself worse in every way, she came to Hospital.

Her condition, on admission, I have attempted to describe above; and it only remains for me to add that, during the seven days she survived, all the symptoms before enumerated became more and more exaggerated. The vomiting was relieved from time to time by the administration of bismuth and similar remedies, but opium was the chief agent employed to deaden, to some extent at least, the frightful agony she was suffering. She took it in various forms, but I think the subcutaneous injection of morphia gave her the most relief. The fact that labour had never commenced, and the knowledge that the child had been three days in the peritoneal cavity before her admission, together with the existence of active general peritonitis in a feeble exhausted subject, rendered all obstetric interference quite out of the question.

The necropsy was performed the day after the death of the patient, and the following are extracts from the notes taken on that occasion. The body was much emaciated and ill-nourished. The abdomen was extremely distended and tympanitic. There were scattered tubercles in

both lungs, but, with this exception, the thoracic organs were normal. On opening the abdominal cavity, a quantity of most offensive gas escaped; and, on reflecting the skin, the body of a full-grown male child presented itself. The nates pressed against the under surface of the liver, and displaced that organ upwards. The body crossed the peritoneal cavity, and the head was found deep in the left iliac fossa. The placenta had also been expelled, and was in contact with the face and chest of the child. All the abdominal organs were covered with lymph, and bound together in every conceivable manner; there was, moreover, a large quantity of very dark offensive fluid in the cavity. The fœtus, placenta, and umbilical cord were in a state of advanced decomposition. The uterus was firmly contracted, and occupied its usual position in the pelvis. On its left side, a rent extended from the fundus to within an inch of the cervix. Decomposed clots and shreds of membrane covered the edges of the laceration, which were very jagged and irregular. The bladder, vagina, and rectum had sustained no injury.

## REVIEWS AND NOTICES.

LECTURES ON THE PRINCIPLES AND PRACTICE OF PHYSIC. By Sir THOMAS WATSON, Bart., M.D., F.R.S., etc. Fifth Edition. London: Longmans, Green, and Co. 1871.

[Concluded from page 441 of last number.]

In the lecture on Pulmonary Hæmorrhage, Niemeyer's recent doctrines as to the relationship between hæmoptysis and phthisis are discussed; and, while it is admitted that hæmoptysis may result from the accidental rupture of vessels in a lung previously healthy, and that a portion of the effused blood, being retained in the lungs, may give rise to secondary changes there, it is believed by Sir Thomas that, if tubercular disease is ever a result of such retention, a predisposition to tubercular disease must have existed.

Introductory to the subject of Phthisis Pulmonalis, the modern doctrines relating to tubercle are concisely and clearly set forth. We will endeavour by extracts to indicate the course of the argument.

"The key-note to the latest hypothesis on this subject was struck, I apprehend, when Villemin first announced, in 1865, that tubercles may be introduced into the lungs and other organs of the body by *inoculation*. It seemed probable that the tubercles found in human lungs—the tubercles with which we as physicians have to deal—might or must have a similar origin. But where or whence was the contaminating matter? Now it is asserted by Buhl, and especially insisted upon by Niemeyer, who is the chief expounder of the modern doctrine, that, speaking generally, this problem has been solved; that the source of the tubercles can be assigned. Niemeyer and the rest affirm that the grey granulations, which all agree to call tubercles, are derived in the greater number of cases, if not in all, from pre-existing inflammation—a proposition which you see is exactly the reverse of what Laennec's theory asserts—not that the tubercles are the *direct* product of inflammation. To simplify the explanation, I will confine myself for a moment to what takes place (they say) in the lungs. In pulmonary inflammation, of whatever kind, there will always be inflammatory products. Some of these are from first to last fluid, and are soon and easily expelled through the mouth. Some are more solid, consisting of coagulable and coagulated lymph, or of an unnaturally profuse and crowded cell-growth, or of both of these together. These more solid products often undergo gradually a fatty or other degenerative change, liquefy, and so become reabsorbable, and are actually reabsorbed and gotten rid of; and then the recovery from the inflammation is complete. But in other cases there is no such liquefaction. The mass of cell-forms grows denser and denser, till the compressed shrivelling cells lose something or all of their vitality, and suffer a change which, from the colour and consistence of the resulting material, has received the disagreeable name of *cheese*. Now the new theory says that particles of this *cheesy* or *caseous* matter, whatever may have been its origin, are liable to enter the blood by a sort of internal inoculation, and so to give rise to a crop of miliary granulations which are truly nascent tubercles. And this may happen in lungs which previously to the inflammation were quite healthy, or in lungs which were previously phthisical and tubercular. More than this. Products of inflammation that have not been reabsorbed, but remain pent up in *other parts than the lungs* (trunk of pleuritis, pericarditis, or peritonitis effusions, of chronic inflammations in joints, in bones, in lymphatic glands, and so forth) may and often do undergo the caseous transformation, and so at length give rise to the dissemination of tubercles in the lungs and in other parts of the body. In this way is explained the occasional existence of crude tubercles in lungs which are free from any other

semblance of disease. Blood detained in the lungs after pulmonary hæmorrhage may (it is held) have similar changes and consequences. . . . It is especially maintained by Niemeyer that 'the formation of tubercle never takes place unless preceded by pneumonia terminating in caseous infiltration of the pulmonary tissue'. He elsewhere virtually excepts from this broad statement those rare cases in which (according to his theory) tubercles in the lungs are derived from decayed inflammatory products pent up in other parts of the body. . . . In connexion with these theories, the careful experiments made in this country by Mr. Simon, Dr. Sanderson, and Dr. Wilson Fox, are of extraordinary interest." And the conclusion is thus stated: "Upon the whole, we must believe with Laennec, with Niemeyer, with (I think) Drs. Sanderson and Fox, that the yellow opaque tubercle is often merely an advanced stage of the grey semitransparent granule; but we must also believe that it may occur independently of the granule, and even become its parent."

Defining phthisis pulmonalis, in the words of Dr. Andrew Clark, as "comprehending all progressive consolidations and circumscribed suppurative degenerations of the lung", it is shown to be a disease of many forms and aspects. The chief of these are discriminated and separately surveyed. We extract the following account of the anatomical characters of the lung in cases of "fibroid phthisis", as a model of clear and concise description.

"The affected lung is shrunk within its natural dimensions; and a great part of it is solid, dry, heavy, and tough, and grates sometimes when cut through with a knife. The cut surface is slate-coloured, or like grey granite, or of an iron-grey tint. Through these solid portions run fibrous septa in various directions. The connecting tissue that bounds and separates the pulmonary lobules is hypertrophied and augmented, and therefore unnaturally visible. Cavities are sometimes found in the apex of the lung, or scattered through the indurated parts. These appear to consist for the most part of dilations of the bronchial tubes. Occasionally, however, the ragged sides of a cavity and the offensive odour of its scanty contents suggest the notion of its having originated in circumscribed gangrene. Amid the grey fibroid degeneration may sometimes be seen a few cheesy-looking spots of soft consistence. The pleuræ are often adherent, or, if not adherent, are considerably thickened. Both lungs are liable to this morbid condition; but it is often limited to one lung only, and so far as observation has yet gone, the left lung is most frequently the one affected; and the disease begins almost always in the upper lobes."

It is stated in books that in cases of pericarditis distension of the pericardium with fluid beyond a certain amount stops, for a while, the friction-sound. Sir Thomas demurs to the accuracy of this statement, and suggests that this temporary suspension of the friction-sound "has been more often inferred as probable than actually observed; inferred through a supposed analogy with the friction-sound of pleurisy." He explains that "the two cases differ materially. In pleurisy with effusion the yielding pulmonary surface is held apart from the fixed and rigid costal surface during the successive acts of respiration; whereas, the tilting movements of the heart against its loose containing bag, can seldom fail to bring the roughened surfaces into partial collision, especially towards the base of the organ. I find that Dr. Latham's experience led him also to say, that serous effusion within the pleura *always* obliterates the attrition sound, and that serous effusion within the pericardium *generally* leaves it unaltered."

In the treatment of peritonitis, as also of obstinate obstruction of the bowels, the value of opium is strongly insisted upon. In the latter class of cases "we seek to restrain within salutary limits the healing force of nature; to moderate without suspending the propulsive movements of the affected bowel."

By the kind permission of Sir Thomas Watson we some weeks since had the satisfaction of making our readers acquainted with his views as to the mode of diffusion, the pathology and the treatment of cholera; it is, therefore, scarcely necessary for us to say that he has treated this subject with his usual ability, and that he adopts the doctrines and the practice which have long been advocated by Dr. George Johnson. The theory of choleraic collapse he believes to be "a reasonable theory, it is founded on a true analogy; it is consistent with the symptoms noticed during life, and with the conditions discovered after death. We may therefore legitimately regard it, until fairly refuted, as a sound as well as a most ingenious and important theory. In truth, it derives strong confirmation from the fact that it unlocks, like the right key, the whole of the pathological intricacies of the disease." Now this is more than can be said of any other theory of the disease; and, in short, it must in fairness be conceded, that while Dr. Johnson's theory of collapse has successfully withstood all the assaults that have been made upon it, and they have been neither few nor feeble, all other theories have been shown to be untenable, on account of their obvious incon-

sistency with acknowledged facts. Then it follows, as Sir Thomas Watson says, that "If the doctrines advanced by Dr. Johnson be well founded, it must be wrong to dam the choleraic poison and its products within the body." It is now acknowledged by all competent authorities that the brandy and opium treatment of collapse is a mischievous mistake, and our recently published reports of the treatment adopted by various London and provincial physicians, have shown that evacuates, diluents, acids, antacids, and other comparatively inactive and unrepulsive remedies, have largely superseded the use of opiates and astringents in the treatment of diarrhoea. In fact, it appears, that an indiscriminate opiate and astringent treatment is now becoming as unfashionable as we believe it to be unscientific. It is no argument against the theory and practice of elimination in cholera to assert, that castor-oil fails to cure cases of extreme collapse. To expect such a result is unreasonable; yet it is notorious that the evacuant or cleansing principle of treatment has sometimes been brought into discredit by its employment in cases of collapse which were obviously beyond the reach of all remedies except, perhaps, injections into the veins.

Amongst the lectures that have been rewritten and extended is that on worms, and other human parasites. The results of the most recent researches in this important but unpleasant department of natural history, are given with characteristic clearness and completeness.

In looking through the lectures on Liver Disease, we find condensed within the space of two pages the leading facts that have been ascertained with regard to *acute or yellow atrophy of the liver*. Then, with regard to the relation between hepatic abscess and dysentery, it is admitted that in some cases the link of connection between them may be that which Dr. George Budd suggested; namely, that there is a primary dysenteric ulceration of the bowel, and a secondary pyæmic infection of the portal blood. It is stated, however, that, in this country at least, "dysentery often occurs without leading to abscess of the liver. During an epidemic dysentery in the Penitentiary at Millbank, among many hundred cases, not one (according to the testimony of the late Dr. Baly) was complicated with hepatic abscess. It is believed that in the hepatic abscesses associated with dysentery in hot climates, what Dr. Murchison calls *tropical abscesses*, the two morbid conditions are mostly, or often, the common result of one and the same cause, and not connected together as cause and effect. The abscess may occur without any dysentery; or precede the dysentery when both occur in the same person; or sometimes be a pyæmic consequence of the dysentery. These opinions are held by Dr. Murchison, as the upshot of observations made by himself while residing in Burmah."

In describing the pathology of cirrhosis of the liver, Sir Thomas, relying upon the authority of Dr. Beale—an excellent authority upon this subject—rejects the commonly received doctrine that the anatomical changes are mainly due to chronic inflammation, and a consequent increase of connective tissue. "Careful examination of the cirrhotic liver demonstrates that the change commences in the hepatic cells, which, from some vice in the blood, undergo degeneration, shrink and shrivel up, and are gradually destroyed, from the circumference of the lobules towards their centres. The lobules themselves are seen to be wasted, and the spaces between them occupied by a fine white material, looking like fibrous tissue, but being granular rather than fibrous." This appearance of fibrous tissue is believed, and shown by Dr. Beale to be due to the wasted remains of ducts and blood-vessels, rather than to the presence of any adventitious tissue.

The subject of fever is discussed at considerable length, and the spontaneous origin of any of the specific forms of fever is held to be extremely doubtful. "The main argument for this view (of their spontaneous origin) is the frequent occurrence of each of these diseases when no exposure to contagion can be traced or easily imagined. But the same argument would be equally valid in favour of the spontaneous origin of small-pox, which scarcely any one, I suppose, would now maintain. 'The evidence (Dr. Budd truly observes) is negative only, and consists solely in our inability to trace with the eye the continuity of a chain whose connecting links are known to be invisible. To conclude from this that no chain exists is palpably absurd.' There are a thousand unsuspected ways in which the invisible contagion may be conveyed."

We have endeavoured by our extracts, and by reference to some of the more prominent subjects, to indicate the extent and the thoroughness of the revision to which these lectures have been subjected. The result is that, as a text-book on medicine, the work is unrivalled, combining as it does, in an extraordinary degree, scientific accuracy, practical wisdom, and an unapproachable charm of style. These characteristics will insure its popularity with students and practitioners, and even with educated general readers, who never fail to appreciate a clear statement of scientific truths. We were once assured by an eminent dignitary of the church, that his familiarity with Watson's *Practice of*

*Physic* had on more than one occasion secured him the victory in a discussion with members of our profession! It appears, then, that if any of us are unacquainted with the teachings of this great authority, we run the risk of being defeated in argument by a dean or a bishop, or some acute and learned lawyer.

## BRITISH MEDICAL JOURNAL.

SATURDAY, OCTOBER 21ST, 1871.

### MEDICAL RELIEF AT HOSPITALS.

THE correspondence relating to this subject still continues. The abuse of our hospitals—more especially of their out-patient departments—seems to be admitted by all the writers, though there is some difference of opinion as to its extent and remedies. Sir Charles Trevelyan, who regards the question as a statesman and philanthropist, appears to think the evils which the out-patient departments are inflicting upon society so great that they ought to be abolished altogether, in order that those who now frequent them might be obliged to apply either to a private practitioner or provident dispensary on the one hand, or to the Poor-law medical officer on the other. This was also the view of Mr. Kitto, to whose letter, announcing the closure of the out-patient department at the Poplar Hospital, we last week drew attention. Other correspondents, without going quite so far, are of opinion that the applicants for out-patient treatment should be carefully sifted. One writer proposes that they should pass through an "inquiry office", similar to that which the Charity Organisation Society has now established in most districts of London. This is a suggestion worth bearing in mind, and might easily be tried. An official of the class employed by this society might be engaged to give tickets to the out-patients on their application at the hospital. A little practice would soon enable him to judge which were suitable for hospital treatment, which required Poor-law relief, which should be directed to the provident dispensary, and which were above the level of all these forms of charity; and the means at his disposal would enable him rapidly to investigate any case about which there was a doubt. Thus with comparatively little expense, and without anything like harshness, the benefits not merely of the hospital, but also of other kindred institutions, might be greatly enhanced. Another correspondent seems inclined to treat the evils somewhat more lightly, and to throw the burden of scrutinising the cases upon the physicians and surgeons who see out-patients. This is a proposal to which we strongly object, and against which we must enter our protest. The assistant-physicians and surgeons have quite enough to do already in examining and prescribing for their cases, and in giving clinical instruction upon them, without being always on the watch to detect an abuse or expose an impostor. Seeing out-patients is no easy task. It requires a great deal of energy to transfer the mind rapidly from one case to another; and the physician or surgeon ought to be able to give his undivided attention to his work. But even if he had time and strength to devote to sifting the patients, it is a duty which he ought resolutely to decline. It is alien to the purpose for which he visits the hospital, and scarcely consistent with the dignity of his profession. If the patients are to be scrutinised at all, it ought to be done before they reach the consulting-rooms by an official engaged *ad hoc*—an official who has the special knowledge and aptitude which such delicate investigations would require, and who is conversant with the medical charities of the district, and the particular grade of applicants which each is designed to assist.

Of those who have taken part in this correspondence, almost all have pointed to the provident system as the most hopeful remedy for the existing evils. The public seem at length to be awaking to a fact which has been often put forward in the pages of this JOURNAL—

namely, that as long as the metropolis and the country generally are so deficient in medical provident institutions, so long must we expect to see the free hospitals and dispensaries grossly abused. The first step towards getting rid of this evil is to put good medical attendance within reach of the working classes on terms which they can afford to pay; and this can best be done by that form of "co-operation" which is known as a provident dispensary. To help the poor to help themselves in time of sickness, as well as in other seasons of adversity, is, in the vast majority of instances, a wiser policy and a truer kindness than to treat them on the eleemosynary principle by gifts and doles.

The Secretary to St. George's Hospital adds a fresh item to the correspondence, and one which is of no small importance. He writes to say that at that institution the governors have given up the privileges to which they have hitherto been accustomed; and that the patients recommended by them now stand upon the same level as other cases, and are admitted or not solely with reference to their medical necessities. This is just as it should be, and St. George's deserves all honour for having set a good example. It would be well if the governors of all our hospitals were contented to give their money for the support of the institutions and for the relief of suffering humanity, without the paltry desire of securing certain privileges which experience has shown are very apt to be abused. It would be well if other hospitals were to follow the step which has been taken at Hyde Park Corner, even though their funds should fall off for a time, and the roll of their outpatients be somewhat diminished. In the long run they would not be losers. Their subscription-lists would undoubtedly recover themselves when the motives from which they acted were understood, and the charity would stand ever after upon a healthier basis.

#### PUBLIC MEDICINE AT LEEDS.

THE interest of the medical profession in questions of Public Medicine is steadily increasing. Thanks very largely to the influence of this Association, the study of the main problems affecting public health has become recognised in late years as a part of the ordinary work of medical men of all grades, and in all parts of the country. The Public Medicine Section at the annual meetings of our Association has had a great success, and is, we hope, destined to a yet wider extension. That Section has gone hand in hand with the Public Health Department of the Social Science Association, in promoting definite public action in respect to necessary legislative reforms. The great success of their efforts is known; it remains to mould the outcome of the Sanitary Commission into the most satisfactory form, and for this purpose a further labour will be imposed on the Joint Committee of the two Associations.

The extremely able report of the Joint Committee, which we printed two months ago, urges with powerful logic some important modifications of the proposals of the Sanitary Commission. These recommendations of the Committee have been adopted after discussion at the annual general meetings of both Associations; and we presume it will now be necessary to urge them upon the Government by a representative deputation from both these bodies.

Our readers will, we feel sure, thank us for giving this week a full report of the proceedings of the Public Health Department of the Social Science Association. The problems discussed are important, not more by their magnitude and close relations to the vital progress and physical welfare of the people, than by their pressing and constant urgency. They relate to events which every day impede the medical man in his saving work, and as to which he is incessantly consulted. The following is the official appreciation of the work done in the department this year.

"In the Public Health Department, the first special question, relating to the disposal of sewage, excited unusual interest. There was a very general feeling in favour of sewage-irrigation schemes for the disposal of the excrement of large towns. On the special question as to the means for promoting the health of factories and workshops, the

papers of Dr. Arlidge and Dr. Stallard deserve special mention; and amongst the voluntary papers brought before the notice of the members, that of Dr. Rumsey, on the progressive degeneracy of race in the town populations of Great Britain, and of Dr. Acland, on the habits of the labouring classes in rural districts, were of great interest and value. A large amount of interest in the sanitary improvement of Leeds was aroused by the paper of Dr. M. K. Robinson, on the measures which have been taken by the Corporation of Leeds to improve the sanitary condition of the town within the last three years. The report of the Joint Committee of this Association and the British Medical Association on the report of the Sanitary Commission was discussed both in the opening address of the President of Council and in the department, where it was unanimously agreed that the Joint Committee should still continue their labours, both with a view of obtaining some modifications of opinion expressed by the Commission in relation to enlarged areas for administration of health-laws, and for securing officers of health with better qualifications than what is proposed. In connection with this department it may be mentioned that the Sanitary Exhibition has excited great interest, and has been visited during the week by 35,000 persons. A special report upon it has been drawn up by the honorary secretary, and will be ready for presentation at the next Council."

#### THE TREATMENT OF SYPHILIS BY THE HYPO- DERMIC INJECTION OF MERCURY.

THE treatment of syphilis by the subcutaneous injection of mercurials—usually corrosive sublimate—which was some time ago brought under the notice of the profession in England by Dr. Walker of Peterborough and others, has had much attention devoted to it by surgeons on the Continent; and the method has had both its supporters and its opponents. We have before us a recent article by Dr. Sigmund,\* the well-known syphilographer of Vienna, in which he examines the subject with care and impartiality. It will be seen from the subjoined abstract, that, while he does not hold with the more enthusiastic supporters of the method, he sees so much possible good in it as to lead him to regard it as a remedy worthy of further trial, with a view to the determination of its proper place among our therapeutic agents.

He first speaks of the disadvantages said to attend the subcutaneous injection of mercury. These are, the occurrence of tedious subcutaneous infiltration, inflammation, and abscess; pain during the process of injection; the details and difficulties of the process; disturbances of circulation and respiration; stomatitis and salivation; and the inferior success of the method as compared with other plans of treatment.

Subcutaneous infiltration at the seat of injection, he says, no doubt occurs, but it does no harm: the effused material is soon completely absorbed. The occurrence of inflammation and abscess is, on the other hand, very troublesome, and interferes with the treatment; but it depends solely on the manner in which the injection is made, the degree of concentration of the solution used, and the condition of the patient after the operation. Dr. Sigmund has used subcutaneous injection in more than two hundred cases in private and hospital practice, and in two only has there been abscess. His patients have been of both sexes, of various ages and constitutions, and had syphilis in various forms. In some cases, as many as thirty injections were given; generally one each day, sometimes at intervals of two or three days. The injection in almost all the cases consisted of four grains of corrosive sublimate to the ounce of distilled water, as recommended by Lewin. The injections were generally done on the trunk, sometimes on the arm, care being taken to avoid parts that would be laid on or exposed to pressure or motion; and rest and simple care of the part were enjoined. When inflammation and abscess have occurred, it has arisen, in his opinion, not from the operation, but from the patients having been allowed to go about their ordinary business immediately or a few hours after the injection, and from the part operated on not having had sufficient rest and protection.

The pain produced by injection Dr. Sigmund has found to vary

\* Zur Beurtheilung der Subkutanen Sublimat-Injectionen gegen Syphilis. Von Prof. Dr. v. Sigmund in Wien. *Wiener Medizin. Wochenschr.*, Sept. 9th and 16th, 1871.

much in different cases; but in the great majority it was slight and transient; in most it was at once relieved by cold applications. In some cases, however, the pain is severe and of long duration, no matter where the injection may be done, or how gently. Such patients are not fit subjects for subcutaneous injection: even the addition of morphia to the solution does not relieve the pain.

The difficulties of the operation are scarcely worth notice. Good instruments can be easily obtained, and can easily be kept clean and in order. There is no difficulty in the operation itself.

Stomatitis and pytalism are liable to occur if the patients do not carefully and often clean their mouths. Dr. Sigmund has found the gums slightly affected in a few only of his patients; but he takes care to use prophylactic measures.

Disturbance of respiration and circulation, or any general disorder of importance, as a result of the action of corrosive sublimate, has never come under his observation. The continued use of all mercurial preparations is attended by a moderate increase in the frequency of the pulse and rise in the cutaneous temperature. Disturbance of the digestive organs often occurs, but is generally clearly traceable to errors in diet. Perspiration and the urinary secretion are but little affected; and those cases in which they are said to have been disturbed in consequence of the injection, must be regarded as exceptions.

In speaking of the alleged advantages of the hypodermic treatment, Dr. Sigmund says that one of them—the possibility of the patient continuing to exercise the part operated on and to go on with his ordinary labour—is but limited. He insists on the necessity of rest and care of the part, for a time at least, not only because a neglect of this precaution is liable to lead to the occurrence of inflammation and abscess at the seat of injection, but also because in many cases it is necessary to apply local treatment to the syphilitic manifestations. He more strongly insists on the necessity of care, as he teaches that free air and exercise are integral parts of the treatment of syphilis.

An essential advantage of the subcutaneous injection of mercury, and one that cannot be sufficiently insisted on, is the precision of the remedy. The surgeon knows the when, the how much, and the where, of the introduction of the medicine into the system; and he can determine most accurately the locality, the time, and the interval for repetition, of the dose. Further, the patient is saved from the immediate disturbance of the digestive organs which is liable to attend the administration of mercury by the mouth.

The two factors, Dr. Sigmund says, that are necessary before a long and repeated series of observations can enable a definite conclusion to be arrived at as to the value of the treatment, are, on the one hand, perfection of the mechanical details of the operation, and careful attention to the diet and hygienic condition of the patient. No clinical observer is as yet in possession of facts whereon to ground a final judgment of the method. We find—unfortunately not unfrequently—that in certain cases of syphilis all the ordinary means of treatment fail, or are contraindicated; and hence subcutaneous injection must be regarded as a valuable addition to our resources. According to Dr. Sigmund's experience, it may be employed in simple papular, pustular, and squamous syphilides, in simple catarrhal affections of the fauces and larynx, in diffuse inflammation of the joints, muscles, tendons, periosteum, and perichondrium, and in syphilitic neuralgic affections; and it may also be tried empirically in cases where other means have proved unsuccessful, or where for some special reason on the part of the patient their use is contraindicated. To cases of the kind here enumerated, he would for the present limit its use in private practice. Clinical observation, on the other hand, must take a wider range. As far as his observation—which, he says, is as yet limited—has gone, Dr. Sigmund is led to consider as unfounded the assertions put forth by the supporters of the plan, that the development of secondary syphilis is prevented by employing subcutaneous injection in the earliest stage—that of induration. In all the cases which he has observed, the consecutive cutaneous and mucous syphilides have appeared, just as they do in patients who have been treated only locally or not at all. One great advantage which attends

subcutaneous injection in common with friction and fumigation, is the possibility of giving at the same time internal remedies, such as quinine, iron, the iodides, cod-liver oil, etc. This advantage is not a small one; for such combination is often of the highest value in syphilitic cases.

The determination of the relative value of the hypodermic injection of mercury in syphilis is, Dr. Sigmund says, a very important question, and one that can only be solved by continued experience. Before a correct judgment as to the value of the treatment can be arrived at, observations must be carried on for several years, on cases of syphilis presenting all the varied forms of the disease. He has, he says, hitherto specially advocated mercurial inunction; but he would cease to do this, if extended experience showed him an equally good or a better means of treatment.

---

A COMMITTEE of the Keighley Board of Health have recommended that a Medical Officer of Health shall be appointed for the town.

OPERATIONS at St. Thomas's Hospital will henceforth only be performed on Wednesdays at two o'clock.

THE subscriptions of the Indian Army for the Sick and Wounded Fund during the late war, amounted to 37,000 rs.

AT the meeting this year of Russian naturalists in Kiew, the Section of Chemistry was presided over by a lady named Anna Volkow.

MR. DIGBY SEYMOUR, Recorder of Newcastle, states that the death-rate during the strike had risen from 25 to from 40 to 50 in 1000, much of the increase being attributable to the effects of privation.

---

A VOLUNTEER Medical Association has been formed in Sydney, New South Wales, on the model of that first proposed for this country by the BRITISH MEDICAL JOURNAL.

---

CHOLERA has reappeared at Bushire, and is said to have carried off many persons. The poor are still in a miserable condition, and four or five deaths occur daily from starvation.

---

A RETURN to the House of Commons has been issued this week, of all lieutenants who have been appointed to Royal Naval Hospitals since the year 1830. The list contains eleven appointments from 1831 to 1868.

---

THERE are now three medical candidates for the Coronership of Northumberland, viz., David N. Carr, M.R.C.S. Eng., L.S.A. Lond.; John C. Reid, M.D. Univ. Glasg., L.F.P.S. Glasg.; and Edward Smiles, M.R.C.S. Eng., L.S.A. Lond. The election will take place on Tuesday the 24th.

---

AN interesting collection of drawings, by the best masters of the English school, is now being exhibited at the Gallery of the Institute of Painters in Water Colours. They have been arranged by the Committee of the Hospital for Consumption at Ventnor, to aid in raising funds for the maintenance of the charity.

---

WE (*Nature*) have received the examination-papers for the Scholarship and Exhibition in Natural Science recently awarded by St. Mary's Hospital Medical School. The questions appear to have been very carefully framed to show the attainments of the candidates in chemistry, physics, zoology, and botany; and we congratulate this young school on setting so admirable an example to its older sisters in encouraging a real knowledge of science among its students.

---

MISS M. E. TRAFFORD SOUTHWELL having offered to erect and present to the town of Wisbeach a building for any purpose which might be considered most advantageous to the inhabitants, a public meeting has been held at the Town Hall, the Mayor presiding, to consider the matter, at which it was resolved to accept Miss Southwell's kind offer for the establishment of a cottage infirmary, to be called after the lady.

A TELEGRAM, dated October 15th, states that the fifth Italian Medical Congress was opened that day at the Lyceum in Rome, numerous delegates being present. Cheers were given in honour of the King and Italy.

#### LECTURES ON HELMINTHOLOGY.

DR. COBBOLD, F.R.S., commenced at the Middlesex Hospital, on Tuesday, a course of lectures on parasitic diseases and their treatment. The lectures will be continued on Tuesdays at 4 o'clock, and are open to all members of the medical profession.

#### THE PRIZE SYSTEM.

SOME rather silly and far-fetched objections are occasionally made to the system of prize giving. Lord Granville discussed these objections in a sensible practical way this week on a public occasion. He said: "The first objection that may be made to it is this—that the system of giving prizes is altogether wrong; that it encourages self-conceit, undue emulation and jealousy; and that the acquisition of knowledge ought to be left to higher motives entirely. I believe such an objection to be marvellously far-fetched; and, like other far-fetched things, not accurate or true. I believe that, so long as human nature exists, you must apply to it a system of punishment and reward; but you must take care that the punishment is exercised in such a manner as to be deterrent in its character, whilst the reward should be justly and properly applied, and never given except in cases of real merit."

#### THE HALIFAX INFIRMARY.

SOME time ago, Sir F. Crossley offered the handsome donation of £10,000 to the Halifax Infirmary, on condition that a new building should be provided on a more suitable site, and the old structure converted into a convalescent home. The offer was at the time thankfully accepted, a site for the building was chosen, and plans for the new infirmary were prepared by Mr. Bakewell of Leeds. The plan provided for ninety-one beds, at a cost of £22,050, and embraced arrangements by which the building could be extended in accordance with the growing demands of the district. We observe, however, that there is now some doubt whether the estimated expenditure upon the new infirmary can be at present obtained, and it was therefore decided to allow the whole question for the present to stand over.

#### WEST KENT MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society, held on October 13th—Dr. Prior Purvis in the Chair—the following gentlemen were elected officers for the ensuing session. *President*—J. M. Burton, Esq. *Vice-Presidents*—E. Clapton, M.D.; A. Roper, Esq. *Council*—J. Anderson, M.D., W. Carr, M.D.; S. Giles, M.D.; R. Gooding, M.D.; W. Lockhart, Esq.; Chas. Nind, Esq.; J. C. Thorowgood, M.D. *Treasurer*—Prior Purvis, M.D. *Secretary*—J. P. Purvis, Esq. *Librarian*—G. G. Bothwell, L.R.C.P.E. The newly elected President, Mr. Burton, delivered an inaugural address. The night of meeting was altered from the second to the first Friday in the month.

#### MAYNE'S EXPOSITORY LEXICON.

WE understand that the Council of the New Sydenham Society have purchased, from the representatives of the late Dr. R. G. Mayne, the copyright of his *Expository Lexicon*, in the preparation of which he spent many years of assiduous labour. It is intended to produce a revised edition, which shall include definitions of all the terms introduced in recent years into medicine and the allied sciences. A Committee has been appointed for the purpose of considering the best mode of proceeding in the matter, and of laying the foundation of the work by inviting those members of the profession who already possess the *Lexicon* to send lists of such words as have occurred to them as being wanting in the present edition. We have every confidence that, through the combination of skilled labour which the Society has within its reach, a most useful work will be furnished to the readers of modern works on medicine and its cognate sciences, while at the same time the valuable classical and antiquarian character of the present work will be preserved.

#### A NATURAL SOLUTION.

THE female medical movement is gradually receiving a satisfactory and not altogether surprising solution. We mentioned lately that one of the *septem contra Edinam* had contracted a matrimonial engagement; and it is now intimated that another of this devoted band of students is about to enter the bonds of wedlock with a distinguished Scottish journalist. What with tedious delays and the interposing interference of Venus, the siege of Edinburgh is likely to have many points of resemblance to the siege of Troy.

#### THE SANITARY EXHIBITION AT LEEDS.

THE Sanitary Exhibition at the Leeds Congress last week was attended by 35,000 people—a proof in equal degree of the attractiveness of the show, and of the expediency of its being thrown open to all comers without payment. It of course must be regarded as a merely tentative experiment; but it is stated that it is to receive its full development next autumn in an exhibition on a much completer scale, and a Congress to be specially convened for the consideration of sanitary appliances. The good people of Leeds, it is added, are not likely to let drop a scheme which they have once taken in hand.

#### A GREAT NATIONAL SERVICE.

THE admirable and deeply interesting researches of M. Pasteur upon the nature of the silkworm-plague have been made familiar to English readers by the references made to them in the recent discussions on dust and disease. M. Pasteur proved that the disease "pébrine" was one of parasitic origin, and propagated by parasitic ova. He recommended a method of rigid microscopic selection, excluding and destroying all taint. His advice has been adopted with magnificent results. M. Dumas, at a recent sitting of the Académie des Sciences, reported that a large proportion of the French silkworm-breeders have adopted M. Pasteur's advice: the plague is almost suppressed, and next year all will adopt it, and the extinction of the destructive epidemic may be confidently anticipated.

#### THE ANATOMY OF MR. HOME.

IF anything were necessary to cover with suspicion the evidence of the witnesses for "spiritualistic feats", and to crown their pretensions with ridicule, it would be the volume of reports just issued by a society called the Dialectical Society. The most obvious juggling tricks and the most infantile absurdities are described with equal minuteness and gravity by the persons on whose power of judgment the inquiry rests. Lord Lindsay, one of the most important witnesses, for example, swears that he saw Mr. Home, in a spiritual trance, *elongated seven inches*: he measured him against the wall, and marked the place. He explains this by stating that "the tip of the hip-bone and the short ribs separate; in Home they are unusually close together. There was no separation of the vertebræ of the spine." He is, of course, utterly oblivious of the structure of the spine, and does not know that to talk of an elongation by seven inches of the dorsal spine, the bones composing which are bound together by strong fibrous ligaments, is to describe a process which, if carried out to only one-seventh part, must be followed by death. Neither the spine nor the contained spinal marrow are capable of more than very slight extension without disruption and consequent death. The same witness also most positively testifies to "levitation"—Mr. Home floating out of one window and in at another. But he candidly admits subsequently that he was at one time the subject of a singular optical delusion. He used to see a spectral black dog glide along: he often went up to it, and sometimes passed through it. He was then overworked, and he is not now troubled with the black dog. In answer to a question whether Mr. Home's clothes were elongated as well as his body, a gentleman present said that "a space was visible between the waistcoat and trousers". We may observe that most of the spirits seem to wear clothes which "rustle like silk"; and spiritual fustian is the favourite wear of rural (and other) spirits; so that no difficulty need arise as to the elongation of Mr. Home's clothes, any more than of his spinal cord and vertebræ.

## THE RECENT EPIDEMIC OF SMALL-POX.

ONE deeply significant fact has been elicited in the course of the Hampstead inquiry. Into the Small-pox Hospitals of the Asylum Board Managers, upwards of eleven thousand patients have been received during the recent epidemic, in a period of little more than six months; Hampstead alone sheltered more than five thousand. No metropolitan hospital, except that at Highgate, would receive these patients, and, but for the rapidly improvised hospital accommodation, most of these patients must have remained at home as foci of disease. This enormous number of patients received will show at once the magnitude of the recent epidemic, and the great services which the new establishments have rendered. But for them the epidemic must have continued much longer and spread far more widely. For their establishment the public are indebted to the efforts of the Metropolitan Workhouse Infirmary Association, and the resulting legislation by Mr. Hardy. It is satisfactory to find that the mortality of these small-pox asylums does not in any degree exceed the standard mortality of the disease in epidemic periods. It is highly important also to note that the same absolute immunity from contagion has been secured for all the servants, nurses, and attendants of the hospitals by re-vaccination, and that the one solitary exception of a nurse who took the disease and died is the exception which proves the rule. She was the one person who, for some reason, was not vaccinated.

## WELL-DIRECTED LIBERALITY.

MRS. BROOKE of Selby has, in order to carry out the wishes of her late husband, the Rev. Richard Brooke, intimated her intention of giving £30,000 to the Royal Albert Asylum for Idiots, Lancaster (half immediately), £30,000 to the Leeds Infirmary (half immediately), £15,000 to the York County Hospital, and £10,000 to the Leeds Convalescent Home.

## CHOLERA IN RUSSIA AND GERMANY.

THE returns from St. Petersburg show that on September 6th there were 106 cases under treatment. During the week from September 6th to 12th, there were 71 new cases, 56 recoveries, and 30 deaths; from September 13th to 19th, 27 new cases, 40 recoveries, and 22 deaths; and on the 20th there were 56 cases remaining under treatment.—In Königsberg, from September 23rd to 29th, there were 51 cases and 36 deaths; from September 30th to October 6th, 18 cases and 15 deaths.—At Altona, during the week ending September 21st, there were (besides 8 cases remaining under treatment) 14 new cases, 5 recoveries, and 15 deaths; in the week ending on the 28th, 2 new cases, 2 recoveries, and 2 deaths.

## THE SEQUEL OF A STRIKE.

WE have made inquiries as to the effects of the late strike at Newcastle-on-Tyne, and are informed by Mr. H. E. Armstrong, the Resident Medical Officer of the General Dispensary, that the returns of the Dispensary for the past four weeks show that both the number of admissions and the death-rate are above the average of the corresponding weeks in former years. Thus, from September 14th to October 14th of this year, there were 291 admissions by letter. During the same period, 20 deaths occurred, or over 6.8 per cent. The corresponding weeks of 1870 show 214 admissions by letter, with 11 deaths, or 5.1 per cent.; and for 1869, 224 cases, with a death-rate of less than 5.8 per cent. Although a large proportion of Dispensary letters proceed from the subscriptions both of employers and workmen at the different factories, yet during the strike none have been issued by those subscribers. Dispensary letters in general are at present scarce. The difficulty of obtaining medical attendance for the strike hands and their families has, therefore, been considerable. Yet the increase of admissions to the Dispensary is chiefly attributable to the privative effects of the strike. That the diseases treated have been due to starvation is shown by the great draught on the Samaritan Fund, which supplies beef and wine to such Dispensary patients as require them.—At the Small-pox Hospital, several cases of that disease have been observed

in persons more or less physically reduced, in consequence of being thrown out of work. In all of these the disease was undoubtedly rendered more grave by the previously existing condition. As yet during 1871, the place of typhus in Newcastle has been occupied by small-pox. But the want entailed on the working classes by the late strike is only too likely to prepare the way for an outbreak of fever on the accession of cold weather.

## RETURN OF INDIAN TROOPS.

IT has been over and over again represented to the military authorities, that the sudden change from the climate of India to that of an English winter, to which many of our troops sent by overland route are exposed, is productive of great injury to the health of the men, but no steps of importance had been taken to mitigate the hardship thus entailed upon soldiers. We learn, however, that Lord Napier of Magdala has shown that consideration for the welfare and comfort of the private soldiers which has been strangely neglected so long, by issuing an order to the effect that medical boards shall assemble in the several circles of India to ascertain what men of regiments under orders to embark in the coming cold season for this country will be unable to bear the rapid change to our winter climate, and that those who are not passed as fit by the boards shall be sent by the Cape route, thus diminishing, as far as possible, the risks of sudden change.

## THE REPUBLIC OF LETTERS.

PROFESSOR VIRCHOW published lately in his *Archives*, and has now reprinted for general circulation, a paper with the title "After the War", in which he seeks to allay the remaining bitterness of the quarrel, and to obtain for France, in the minds of his countrymen, a due recognition of her many and great merits. It appears, however, that his friendly offices receive little encouragement, from one side at least, and in circumstances, too, where nationality might well be forgotten. The professor lately found himself at Bologna, representing German science at the International Conference for Archæology, in which subject he is an authority. According to the story, for which the *Germania* is responsible, Virchow there met certain brother savants from France whose acquaintance he had made at previous scientific meetings. The professor, it is said, coming up to them at the opening meeting, held out his hand to greet them, but the French men of science turned away, with a decisive "*Jamais!*"

## KING'S COLLEGE MEDICAL SOCIETY.

THE introductory meeting of this Society was held on October 12th at King's College. Dr. Rutherford, President, occupied the Chair, and was supported by Dr. Johnson; Mr. John Wood, F.R.S.; Dr. Bentley; Mr. Cheere, the Treasurer of King's College Hospital; and other members of the hospital staff. Dr. Cotterill, one of the vice-presidents, read the inaugural address on "Medical Reform". After the usual complimentary speeches the meeting was brought to a close.

## CHOLERA IN THE EAST.

THE last advices from the East state that cholera is slightly on the increase. Isolated cases have occurred in several parts of the city of Constantinople, in which city, in the week ending September 26th, there had been thirty cases, out of which nineteen were fatal cases. Quarantine is now enforced in all Ottoman ports. Cholera is, however, reported to have ceased in Brussa.

## A BOARD OF GUARDIANS IN A DIFFICULTY.

THE Narberth Board of Guardians have found themselves in a difficulty from the resignation of Dr. Evans as medical officer of District No. 3, unless his salary was increased from £35 (which included medicines) to £50 per annum, and their inability to find a member of the profession to undertake the appointment. By way of getting over the difficulty, the Board have given notice to the relieving officers that in case of any necessity the nearest medical man (perhaps ten miles distant) may be employed, at the expense of the guardians, for the

next three months. Now, considering that the union embraces sixteen parishes, covering an area of 40,000 acres, in a mountainous country, in many parts inaccessible by any kind of vehicle, with a scattered population of 4,744, we think we may safely predict that the guardians will find that, for the sake of attempting to save a miserable £15 a year, they have been penny wise and pound foolish.

#### PATHOLOGICAL SOCIETY OF LONDON.

THE opening meeting of this Society was held in the council-room of the Royal Medical and Chirurgical Society, Berners Street, on Tuesday evening; Mr. Timothy Holmes, Vice-President, in the chair. There was a fair attendance of members. Some interesting specimens were exhibited, pre-eminently one of Multiple Hydatid of the Peritoneum by Dr. Murchison. The plethora of mediocre specimens, and the undue haste of the exhibitors customary at this Society, were happily not features of the first meeting. May this augur well for the rest of the session! The popularity of the Society has seemed at times to threaten its utility. Specimens which present features of no particular interest to any one but the exhibitor have constantly been brought to the Society, to the exclusion of others of greater value. But this is not all. The work of the evening is thus rendered generally so heavy that a taste has become engendered, whereby anything short of a constant supply of plates filled with viscera throughout the meeting is distasteful to the bulk of the members. Pathological papers are consequently discouraged, and exhaustive discussions unknown. The Society is, in fact, more of a Morbid Anatomy than a Pathological Society. Selection of specimens would no doubt be difficult, if not impossible; but if discussion were encouraged, the specimens would then decrease in number, the interest of those exhibited would be greater, and their value still more enhanced by their fuller consideration. Members would thus learn to be less impatient of scientific pathological papers, which we are confident would soon multiply.

#### THE CLINICAL SOCIETY.

THE first meeting of this Society was held on Friday of last week. Dr. Gull, President, occupied the Chair. On taking the chair, he congratulated the Society on the publication of the fourth volume of its *Transactions*; and, without making a formal address, expressed a hope that the coming session would be still more prolific of useful results. Clinical medicine, he remarked, still required, and must for ages to come require, the united efforts of all practical men to promote more exact diagnosis of disease and its therapeutics. The aim of the Clinical Society was not limited to the report of cases alone, but included the advance of every kind of knowledge which could make our bedside-work more exact was acceptable. The value of a sign or symptom in diagnosis; the improvement or invention of better means for physical examination; the operation of any therapeutical method or drug; in fine, any means promoting the end in view, was the fit object for the consideration of the Clinical Society. There was, indeed, no practitioner who had not opportunity at some period in his daily work of adding something to the stock of our knowledge in these respects. The contribution might, perhaps, seem insignificant; but it could not be really so if, by due proof, it could be made to take its place among the facts of Nature. The attendance was, we regret to say, meagre, and not commensurate with the interest and importance of the subjects brought under discussion. The tact and skill of the President succeeded in raising a discussion of interest on a subject collateral to the paper read, but not directly involved in it. Notwithstanding the ability of the President, however, and the tact with which he seized the flying opportunities of raising a discussion, he with difficulty succeeded. The discussions at the Clinical Society are by no means equal to what might be expected; and if the Society is to fulfil the hopes which were entertained of it, more vigorous means must be taken for obtaining good papers, and for collecting together on the nights of meeting gentlemen specially acquainted with the subjects to be discussed, and who are disposed worthily and seriously to debate them. This will, do doubt, involve some labour and increased energy on the part of the secretaries and

other officers. But Dr. Buzzard and Mr. Lawson will not, we are persuaded, think labour devoted to the progress and successful development of the society to be ill spent. *Defluit annis dum rusticus expectat* is an old saying, from which the officers of a young and ambitious society should take an useful lesson. The Clinical Society is capable of great things; it has done good things; but it is as yet only a half success: and more energy, a more skilful distribution of work, and a more fertile initiative, are necessary if the society is to advance. Not to advance would be to recede.

#### THE CORONERSHIP OF NORTH NORTHUMBERLAND.

DR. REID of Newbiggin has announced his candidature for the vacant office of coroner of North Northumberland. Dr. Reid is well known as a man of energy, experience, and information. Many of the improvements, especially the sanitary ameliorations, of Newbiggin, have been effected through his instrumentality. A very little consideration of the duties of the office of coroner will show the electors that this office is one in which medical knowledge is the first and chief requisite. The object of the coroner's inquiry is to determine the cause of death—not to detect or punish a guilty person: that is a business entrusted to subsequent procedure and a different class of officers—the magistrates and judges. These are properly and necessarily lawyers. The coroner has to make an inquiry habitually requiring not only a complete knowledge of the facts of medical science and the terms of art, but the power of appreciating the precise bearing of the statements made to him—often *ex parte*—by men of medical knowledge; to detect their hollowness, if they be hollow; their insufficiency, if they be insufficient; their falsity, if they be false. More often than not, the coroner has no legal or medical assessor to assist him in testing the technical evidence given before him. It may happen that the medical witness on whose information the coroner is then solely and helplessly dependent is the one person chiefly interested in misleading him. A miscarriage of justice is nearly inevitable in such cases where the coroner has not himself received a medical education, and does not possess the means of forming an independent judgment. Still more often, in the absence of medical evidence or medical assistance on either side, the coroner has to decide whether an inquest is necessary, or whether medical evidence and *post mortem* examination are demanded. Legal coroners are likely to be fearfully misled. They have not the preliminary knowledge necessary to awaken suspicions in cases apparently plain and above board. They are apt to be unduly suspicious where a little more thorough knowledge would have saved pain, trouble, and expense. The most distinguished authority in this country has expressed his conviction, which all who have inquired into the subject and have had much experience will share, that more secret poisonings escape detection than meet with punishment. The unfitness of legal coroners is largely at the bottom of this impunity.

#### MIDDLESEX AND UNIVERSITY COLLEGE HOSPITALS.

A LETTER addressed to us by the Dean of the Medical School of the Middlesex Hospital contradicts a statement to which a contemporary has once again given currency this year—that special privileges have been accorded by the authorities of the Middlesex Hospital, for clinical study in their wards, to those students of University College for whom the University College Hospital may be unable to find clinical accommodation and teaching. The question has been discussed, as is well known; but no arrangement has been made, other than that students from University College, as from all other hospitals, are welcome to the wards of Middlesex on paying the usual clinical fees; a prior claim for clinical offices being, moreover, reserved for the students of Middlesex School and Hospital. No doubt an amalgamation of the didactic and clinical teaching of these and other hospitals is desirable, and, if effected on satisfactory and equitable terms, would tend, as we have more than once pointed out, to widen the basis and improve the completeness of medical teaching in the metropolis; but such an amalgamation must be a matter of careful and equitable adjustment, and not favouring the staff of one school more than another. Middlesex

Hospital has no reason to take any step which would separate the interests of its lecturers from those of its medical officers; and the injudicious zeal of the particular *attaché* of the journal in question, which annually prostitutes its columns to these erroneous reports, cannot be agreeable or useful to the authorities of University College Hospital; for, if it temporarily produce an impression that the capacity of the hospital for clinical teaching is increased, the contradictions which such erroneous statements evoke only tend to draw attention more pointedly to the present deficiency of beds for supplying clinical offices for the students of the school. The repetition of such statements and contradictions cannot but be mischievous, and tend to postpone any ultimately satisfactory arrangement. They must be as annoying to University College as to Middlesex Hospital, both which have every reason for seeking to cultivate a close union of interests and a friendly arrangement which should create a great school of medical instruction with five or six hundred beds available for clinical instruction.

### SCOTLAND.

AN EFFORT is being made to secure for Dalkeith and its neighbourhood a small permanent hospital. Serious complaints are made of the incompetency and behaviour of the local authority.

#### MONUMENT TO DR. ELLISON OF TAIN.

A VERY elegant monument has been erected, by public subscription, to the memory of the late Dr. Ellison of Tain, Ross-shire. It is of granite, eighteen feet high, and bears the following inscription: "In remembrance of James Ellison, M.D., who died at Tain, 18th November, 1870. Erected as a public testimonial of the respect and esteem in which he was held wherever his duties led him, and as a mark of public appreciation, not only of his skill, but of his usefulness and zealous attention to his patients. Studiously devoted to his profession, he was eminently successful in his medical career: peculiarly kind, gentle, and considerate, his services were ever ready to the calls of the poor. His memory will be long cherished by many friends. *Semper honos, nomenque tuum, laudesque manebunt.*" The cost of the monument is about £70; the amount subscribed was nearly £160; and the balance is to be presented to a relative.

#### MEDICAL BURSARIES IN THE UNIVERSITY OF ABERDEEN.

WE have had occasion more than once to call attention to the poverty of the Faculty of Medicine of the University of Aberdeen, in so far as bursaries are concerned. There is probably no University in Scotland which offers to the poor student so many opportunities of acquiring an excellent general education as Aberdeen, and these advantages are thrown open *pauperibus* by means of the numerous small annual bursaries possessed by the University, which are mostly tenable for four years. But although the Faculty of Arts has become enriched, the Medical Faculty, strange to say, practically possesses no such prizes for the student of medicine. It is, indeed, true that one medical bursary exists, and has been dispensed under a system, or rather want of system, which it is generally believed has failed to meet with approval, but the existence of this bursary scarcely even qualifies our statement. To remedy such a state of matters, a Committee was some time back appointed by the General Council of the University, and on Wednesday of last week they presented an interim report. They considered that the best method of procedure was to have a statement drawn up, setting forth the great want of bursaries in the Medical as compared with the other Faculties in the University, and indicating the condition under which such bursaries would prove most useful. It was the opinion of the Committee that such bursaries should be open to all, and gained by competition; that the competition, while embracing the parts of general education, should give prominence to natural science, and that, after two years had expired, the tenure of these bursaries should depend for the next two years on the passing satisfactorily of an examination in the earlier branches

of the medical curriculum. The report met so far with the approval of the meeting that the members of Committee were reappointed to prepare their statement. When thoroughly matured it will be well to circulate the report amongst all medical graduates and alumni, inviting their co-operation in a matter of so much importance to the University. A very remarkable proposition, which had the merit, certainly, of striking originality, was brought forward by a member of Council, the chief principle, as we shall call it, of which was, that the arrangement of the medical classes in the University curriculum should be dependent on the hours of visit at the dispensary!

### IRELAND.

A HANDSOME tablet has been placed in the Derry Cathedral to the memory of the late Dr. Thomas Henderson Babington.

#### A SALUTARY ACT.

THE Irish Poor-law Commissioners have exercised their prerogative in the case of the Millstreet Union, county Cork, and have dissolved the Board of Guardians of that Union, appointing paid officers in their stead. The charges against the guardians are stated to have been—utter indifference to the needs of the helpless poor committed to their charge, constant irregularity in attendance, frequent insufficiency in the number of guardians to constitute a quorum, and a constant inattention to the financial affairs of the Union. It is many years since the Commissioners considered it to be their duty to take such a decided step; and we have no doubt that it was the result of mature consideration, and much required. It will have an important effect in stimulating other boards to a clearer appreciation of the necessity of the performance of their duties. The same proceeding might occasionally be adopted with advantage in the case of certain English boards of guardians.

#### REGISTRATION IN THE MEDICAL SCHOOLS.

THE registration of students at the eleven metropolitan medical schools has been completed, and the returns have been made to Mr. Charles Hawkins, F.R.C.S., the Government Inspector. From these, it appears that, notwithstanding the large number of rejections during the present year in the Arts Examination at the University of London, the College of Surgeons, and Society of Apothecaries, there is an increase of 35 in the new entries over the number registered in October 1870.

The following represents the number of students registered at the College of Surgeons at each of the hospitals, including new entries; but there are also some gentlemen pursuing their professional studies for the Fellowship of the College of Surgeons at each of the institutions who are not required to register.

	New entries.	Total students.
1. University College .....	88.....	271
2. Guy's Hospital.....	86.....	328
3. St. Bartholomew's Hospital ..	81.....	255
4. St. Thomas's Hospital .....	58.....	145
5. King's College.....	43.....	121
6. London Hospital.....	29.....	99
7. St. George's Hospital.....	22.....	85
8. St. Mary's Hospital .....	21.....	61
9. Middlesex Hospital.....	19.....	46
10. Charing Cross Hospital .....	11.....	40
11. Westminster Hospital.....	10.....	23
Totals.....	468	1468

The above includes also those studying for the dental profession.

The following analysis of registrations during the present decade will doubtless prove interesting. In 1861, there were 1228 students at the eleven recognised medical schools; in 1862, 1116; in 1863, 1045 (in this year the Grosvenor Place School of Medicine was closed); in 1864, 995; in 1865, 1013; in 1866, 1027; in 1867, 1125; in 1868, 1194; in 1869, 1241; in 1870, 1298; in 1871, 1468. The returns from the provincial hospitals and schools have not yet been completed for Dr. Ogle, the recently appointed successor of the late Dr. Cursham.

## SOCIAL SCIENCE ASSOCIATION.

*Annual Meeting held in Leeds, October 1871.*

## DEPARTMENT OF PUBLIC HEALTH.

*President:* George Godwin, F.R.S.—*Vice-Presidents:* Charles Chadwick, M.D., D.C.L., Edward Filliter, C.E., J. D. Heaton, M.D., Frederick J. Mouat, M.D., F. S. Powell, and Robert Rawlinson, C.B., C.E.—*Secretaries:* William Clode, and William Hardwicke, M.D.—*Local Secretaries:* T. Clifford Allbutt, M.D., and M. K. Robinson, M.D.

*Thursday, October 5th.*

THE PRESIDENT, in opening this section, directed attention to the Sanitary Exhibition. Although got up in a very great hurry, and further delayed by the hesitation of some of the exhibitors, it was nevertheless a very valuable collection; and although those gentlemen who had taken the pains to put it together regret that they had not been able to classify the articles more, yet, considering the short time, he hoped that that had been done to a considerable extent. There were some very important inventions, applying to plans, schools, and cottages; and there were a number of dry closets. Mr. Jennings, of London, had sent a number of his sanitary appliances, and, with regard to cookery, there were a number of inventions which might be very usefully examined and reported upon.

SEWAGE OF TOWNS.—The subject of discussion was, "What are the best and most economical Methods of Removing and Utilising the Sewage of Large Towns?"

MR. C. RAWSON, General Manager of the Native Guano Company, read a paper on the Utilisation and Deodorisation of Sewage by the A B C Process. In consequence of the unsuitable works in which the experiments had been carried on at Leamington, and from other unfavourable causes, he admitted that many of the objections which had been made to the process had some foundation in fact, although he must deny many of the theories or hypotheses drawn from them. Only three schemes had been proposed for dealing with the sewage of towns—irrigation, filtration, and precipitation by chemical means; and circumstances might occur in which either would be preferred in practice, while in some instances their combination might be more effective, and lead to improvements in agriculture. By the A B C process all the suspended, and from 60 to 75 per cent. of the soluble matter, could be removed from the sewage, even by the ordinary working of the process. Still greater results might be obtained by further treatment; but even if some portions of the manurial properties did remain in the effluent water, he believed these might be utilised by putting it over the land, and thus all waste might be avoided. With regard to irrigation, certain difficulties must necessarily occur, and were inseparable from the adoption of that system. At least one acre of land was required to utilise the sewage of one hundred adults annually—according to many eminent authorities; but at least scores of towns could not secure the requisite land for their purposes. Again, neither landlords nor farmers had shown any very strong desire to receive this sewage on to their lands; and land must generally be acquired by town authorities by means of Acts of Parliament. He could not pass on without remarking the probable injury to the adjacent land by its propinquity to a sewage farm; and if the feeling of the richer class of the community was against such a course, what right had we to force on our poorer brethren a process which might result in serious illness to their families from the typhoid and other forms of disease from miasmatic exhalations? Not only, however, did he admit, but he proudly acknowledged, that magnificent crops had been obtained by a judicious use of sewage through irrigation. Their only difference with the most enthusiastic irrigationist was how to give the land the benefit of the valuable constituents of sewage in the most remunerative and least objectionable way. The irrigationist would pour it on the land in what he thought a wasteful quantity, whilst the A B C process would convert the same sewage into a dry, portable, and effective manure. Mr. Rawson described the A B C process in detail. The name was derived from the initials of the chief ingredients used: Alumina, Blood, Clay, and Charcoal. For a considerable time there had been substituted for the ammonia-alum formerly used, a crude sulphate of alumina, which was just as effective, and much more economical. The proportions of these ingredients were adapted carefully to the nature of the sewage, both as regarded quality and quantity. In the manufacturing districts, the condition of the sewage was subject to sudden and violent fluctuations, arising from the waste liquors of all kinds of processes; while in towns where few manufactures were carried on, domestic causes operated similarly, though in a less degree. Experience was required to secure complete

success; but as these changes in the sewage were exceedingly regular, it was not difficult, by a little attention and forethought, to be fully prepared to meet them. The manure had been submitted to the tests of chemical analysis, and of actual use by the agriculturists. From the former, Mr. Rawson said, it met with little favour; while many agriculturists gave unqualified approbation of the native guano used in the garden, the field, and the orchard. Last spring, the demand by those alone who had previously used the guano far exceeded all powers of supply. The price of native guano was £3 : 10 per ton at the works, and the company had already disposed of upwards of 30,000 bags at the price; and in almost every case farmers who had made a trial of it in small quantities eagerly sought for larger supplies. From the unfortunate defects of the Leamington Works, Mr. Rawson was not surprised at some of the unfavourable conclusions drawn by the Rivers Pollution Commissioners, during their two visits to Leamington. They were, however, quite unwarranted in publishing such an attack on the company without more thorough investigation. He hoped their future inquiries into the process would be conducted in a more considerate spirit. In suitable works, not the slightest nuisance arose from the process. Another important feature in the process was that in the A B C works the excreta collected from such receptacles as Moule's or other similar system, might be turned into native guano by mixture with the deposited mud, with probably but a slight addition of A B C mixture. The contents were at once deodorised, and could be dried without nuisance. It was the intention of the company to establish in some central town, in the neighbourhood of which the chemicals could be cheaply obtained, and where there was an abundance of suitable clay, a manufactory of dry A B C mixture. This would relieve towns from the necessity of having a chemical staff. Another important consideration in connection with the A B C process was the comparative cheapness at which the works could be erected. As a comparison, Birmingham would have to incur an outlay of £1,200,000 for land for irrigation, whilst the A B C works would not cost above £50,000. Blackburn was spending £185,000 on an irrigation farm, while sewage could have been treated by the A B C process at an expense of £15,000. The last argument which Mr. Rawson advanced in favour of the A B C process was, that it was successful in a commercial point of view. The metropolis daily poured into the Thames 100 millions of gallons or 448,740 tons of sewage; and it was estimated from experiments, the A B C process would convert this into over 1,000 tons of dry manure, worth annually, at £3 : 10 per ton, the sum, for the metropolis alone, of £1,282,500. The authorities of Leeds resolved some months ago to make an experimental trial of the A B C process. The works, which were situated at Knostrop, to the south-east of the town, and adjacent to the River Aire, were hardly yet completed; but Mr. Rawson trusted that they would be found a success. In conclusion, Mr. Rawson asserted that the A B C process was pre-eminently suited for treating and utilising the sewage of large towns. The effluent water could be made clear, inodorous and almost chemically pure; the process could be carried on free from nuisance, and the profits were large and certain. He felt confident that these would be admitted facts, as soon as the works at Leeds, Bolton, and Crossness were in working order.

MR. HARDWICKE (Secretary) read a paper by Dr. Robert Elliot, of Carlisle, upon the best means of Utilising Sewage. The only system advocated by the author was an elaboration and extension of the plan of Mr. Macdougall, of Penrith, which had been in operation for upwards of twelve years at Carlisle, viz., of immediately carrying off all excreta by underground drainage, with arrangements for ventilation into furnace chimneys, and which at some suitable place or places had its liquid sewage, free from putrefaction, pumped up by steam-power, and, suitably mingled with carbolic acid, applied in rotation by means of long moveable channels or troughs to the adjacent fields. This irrigation had proved highly successful. The indefinite expansion of the plan to suit every case seemed to present no other difficulty than such as enterprise might in every case successfully grapple with. It was submitted that the best method of removing the sewage of large towns was by underground drainage (commanding a constant supply of water) leading to underground tanks, suitable in capacity and number, arranged at equal distances from each other, and forming a circle outside the town; each tank being supplied with ventilation into the furnace chimney of a suitable steam engine, the double use of which should be to work a revolving washer within the connected tank, and to project the well mixed and deodorised sewage to its next destination through mains either at once to the neighbouring fields, or onwards to other tanks and steam-engines similarly arranged, at points further away, wherever such fertiliser may be needed. Such tanks, even in some cases without steam-engines, might be placed on natural or artificial eminences, from which, as in the working of a water-supply, the contents might be distributed by gravitation through service-pipes and

their accompanying arrangement of taps, to any place where the sewage might be wanted.

Mr. SYMINGTON read a paper descriptive of the method of dealing with sewage proposed by Mr. Strang, of Glasgow. The method suited to the existing water-closet system, and would be the means of extending that system on a simple plan to poor and crowded localities, replacing the offensive and unhealthy arrangements common in such parts; and it secured all the valuable ingredients of the sewage in a concentrated form for agricultural purposes. A patent sewage-filter formed the essential feature of the scheme. This filter was so constructed that the urine and solid parts were entirely retained, and the water allowed to flow off free from all contaminating matter. The filter consisted of a cast-iron box, divided horizontally into two compartments by a perforated bottom or grating. In the upper portion of the box above the grating was placed a bed of common ashes. The whole discharge from the soil-pipe entered the lower division, where the urine and solids were retained, while the water passed upwards through the filter, and flowed off into the drain in a perfectly innocuous state. The contents of the lower part of the box might be disposed of in one or other of two ways. By providing a moveable covered ash-box to stand under the filter, the house-ashes and other kitchen-refuse could be deposited there, and when it had received the contents of the filter, the whole could be easily removed by the scavenger, thus doing away with the ordinary ash-pits, dust-bins, etc.; or the filter could be emptied into a close cart and the contents removed in their natural state, as was being done by the cleansing department of the City of Glasgow. This apparatus had been examined and approved of by many scientific and practical men. As to expense, it was urged that, when properly organised, the cost attending the management of this system would not be greater than at present incurred by the emptying and removal of the ordinary ash-pits, etc., which would then be done away with altogether.

Mr. W. T. MCGOWEN, Town Clerk of Bradford, had a paper entitled "The Sewage of Manufacturing Towns; what shall we do with it?" The writer came to the conclusion that, although sewage-irrigation might be resorted to advantageously in the case of small towns where circumstances allowed the proceeding to be successfully and inoffensively carried out, there were sound reasons for holding the system to be impracticable for large manufacturing towns if they were to undertake the whole operation themselves; and that if the sewage of these places were to be applied to the purposes of irrigation, it could only be done in some such way as had been suggested—by the Government making main outfalls to sea sands with a view to their reclamation; and that, meantime, the local authorities would have to direct their attention to the best means of purifying the sewage in the vicinity of the stream to which the water belonged, by mechanical or chemical means, or both.

Dr. F. J. MOUAT had spent thirty years of his life in India, and he considered that the first question to be determined was how to get rid of the sewage in a manner best consistent with the public health. This having been determined, the engineer and the agriculturist could be appealed to. He approved of Moule's dry-earth system, but there were certain defects connected with even this system, and in particular, the chances of disease being propagated by certain forms of organic life.

Mr. W. H. MICHAEL (London) complained that gentlemen read papers which showed that they were totally unacquainted with the first questions essential to the success of irrigation. The author of the first paper had said that a sewage-irrigation farm was a bog, and that it would be detrimental to health. He could never have been at a sewage-irrigation farm properly conducted. The Edinburgh meadows were managed in total contrariety to the very first principles of the proper sewage-irrigation farm. The solid constituents of manure were the worthless part of it, and the first thing in dealing with irrigation was to separate the whole of these, as was successfully done by the admirable method adopted by Mr. Baldwin Latham in his new machine. But any process that tended only to separate the solid constituents of sewage must be put aside as utterly worthless. Those who wanted in the interests of the public health to remove the difficulties in the way of dealing with sewage were not wedded to any one system; but when the subject was discussed, gentlemen advocated their own measures, looking at it as some means of making profitable manure at so much per head of population. The value of the whole of the manure, he maintained, lay in the fluid portion; and it was this fluid portion, the soap-suds, and slops, and the urine, that formed the difficulty, and any system which did not deal with this fluid failed to achieve the primary essential to be adopted in treating sewage. He did not advocate any principle; but having been engaged for many years in seeing irrigation at work, he thought it did promise not only to remove any source of nuisance, but to be extremely beneficial in producing food—because to talk only of rye-grass being produced was an absurdity. So far as he could see

at the present time, irrigation was the only process that answered the necessary conditions, of taking that which it was requisite should be taken from the excreta, and it could be applied to land without creating the slightest amount of nuisance even to persons living in the immediate vicinity. There was no cause of disease which had been shown to have arisen from sewage-irrigation, and the latest experience showed that on sewage-irrigation farms so large a percentage as 10 per cent. could be returned for the money invested by local authorities in the creation of that which relieved them entirely from the nuisance, and which must prove a benefit in every sense to the ratepayers.

Mr. CONYERS MORELL maintained that the proper place to deal with all refuse was at its original source, where it should be rendered inoffensive. He described a plan for dealing with refuse invented by himself, and undertook to fix closets in the town and remove the refuse for nothing.—Mr. R. RAWLISON, C.B., said that for modern communities, gathered together in towns, there were several things that had to be done to secure the public health. The question had to be discussed, for instance, how to remove the slops from the houses. Sewers and drains were necessary to dry the subsoil. There were a great many places where a vast proportion of the mortality was due to the damp and wet subsoil, and therefore there must be sewers and drains. A mathematician could scarcely calculate the addition to the diameter that would be required to carry away the effete water. This being granted, and the sewers laid upon a proper foundation, there was no cost of conveyance. Water would flow to any distance. It was said that the circumstances under which effete matter might pass along the drains corrupted the atmosphere of the houses; but if that were so the drains did so very unnecessarily. Every drain ought to be cut off by a ventilating shaft opening up to the fresh air, so that any gas generated should not pass into the dwelling-house. It was said that dry earth disinfected immediately. If it did, he would say that water stopped putrefaction for a limited time—for a safe time to enable it to flow beyond the precincts of the town; and if that were so, with a properly arranged water-closet there was no trouble—there was simply the pulling of a handle to get the water-supply, and the offensive matter passed away. With an earth-closet, there must be separate intervention at least once a week, but, if it were to be kept perfectly clean, at least once a day. If there were two or three earth-closets in a house, how could the servants be expected to manipulate them in a cleanly manner on all occasions? There would be 365 manipulations a year, if they were daily, and if weekly 52. The value of the manure was twelve shillings per head of the population, and would any one accept that remuneration in respect of the manipulations in his house. The dry-earth system might do for detached dwellings, for large establishments, for gaols, for barracks, for any place where persons were entirely under command, where there was no objection to bear the expense of the separate manipulation, and where the gardeners could be found. He took it for granted that the sewage must be removed, either in the dry or in the wet state. If in the dry state, it was removed necessarily by mechanical means, or by human agency. If in the wet state, sewers and drains having been made under proper conditions, and properly ventilated, the sewage removed itself to any point that was desirable; and where necessary, steam-power might be called into use. With regard to irrigation, he would only say that sewage might be applied to land with perfect success without causing the smallest nuisance, and that probably, according to circumstances, there would be a great income. The conclusions to which he was brought were these—that no human means, so far as was at present known, of treating sewage by chemicals did more than remove one-eighth of the salts of sewage from the effluent water; and that the brightest and best clarified sewage was then in the very best possible condition to be put on the land for the purposes of irrigation. Mr. Blackburn, who had a sewage-farm at Aldershot, would find one acre of ground for any of the patent manure manufacturers, and he would give them his sewage to manipulate—and it was the richest that could be got, there being sixteen instead of eight grains of ammonia to the gallon—if the water were returned to him when they had done with it. He could only say that if such manufacturers by the A B C process could make the manure worth £3 or £4, or any higher amount per ton, they would do what all the chemists with whom he had been in contact told him was impossible. For such counties as Yorkshire and Lancashire the question was very important, because they might expect legislation on the subject. It had been intimated over and over again that Parliament should teach the people what to do, and it had also been said that the Rivers Pollution Commissioners should give some direction. It was, however, he thought, the duty of the Commissioners to inquire, to give the best information, and then let the towns provide a remedy.—Dr. MACMILLAN and Mr. R. CRAVEN offered some remarks.

Mr. P. OVENDEN, Secretary to the Native Guano Company, maintained that the manufacture of manure pursued by the company was

efficient, and alleged that irrigation led to nuisances in the districts where it was carried on.

Mr. C. CHADWICK maintained that the cheapest mode of removal was by water, which arrested decomposition, and carried the sewage away most completely. As to earth-closets in the Tropics, he had no experience of India, but as to the West Indies he had been consulted upon the means of providing deodorants to get rid of very troublesome insects. Decomposition began ordinarily in three or four days, and if proper attention were given to sewage, it would be got rid of in a day. Excreta ought to be in the field, not in mechanical suspension, but in chemical combination. He regretted that in Leeds for thirty or forty years the place should have remained as it was, with a death-rate augmented. There was a very large pecuniary loss to the town occasioned by lost labour and the effects of premature debility, owing to ignorance of sanitary science.

Dr. BAYLIS advocated the establishment of the water-closet system. In Birkenhead, that system was being carried out vigorously and with the best results.

Mr. HOWARD, M.P., corroborated Mr. Michael and Mr. Rawlinson as to the perfect success of the irrigation process. At Bedford, the plans adopted had answered their purpose well, and no nuisance was caused. As a rule, it would be found that arrangements which for efficiency depended upon people attending to them were not such a perfect success as self-acting arrangements.

Mr. Councillor MARSDEN was very much disappointed with what the Association could do for towns that were anxiously considering their difficulties, if all the benefit to be received was represented by the papers read, there being nothing precise and certain in what was recommended. He advised that a system should be taken into consideration by which the different elements of sewage should be kept and dealt with separately.

Mr. C. CHADWICK said that in France and Belgium and other continental cities the system of separation had been tried, and it had universally failed. The death-rates approached the death-rates of Leeds, when they might have been reduced by one-third.

Mr. MARSDEN said that the system was in work successfully in New York.

Mr. P. H. HOLLAND said that the public health question was largely affected by economy; and, although there might be fifty ways in which excreta might be dealt with, they were too expensive. The only good plan yet possible was to remove the filthy matter quickly by water-carriage. He felt that five shillings a ton ought in reality to be the cost of the A B C manure; and he contended that it was of very little use to the agriculturist.

Mr. Councillor MATHERS said that water had been more recommended than any other system; but no one yet could say that this or that was the best scheme, because the determination of this would depend upon the position of towns. He thought the A B C system the best hitherto: it certainly dealt with the sewage better than any other system that had been made known to the Town Council of Leeds, and the manure had turned out well in the hands of several farmers.

M. A. LEIGHTON did not oppose irrigation, but criticised some points, and spoke of charcoal as the most effective deodorant.

Mr. DE RENZY, Commissioner in the Punjab, described the method of removing excreta mixed with earth from gaols in his district, and stated that it worked successfully. The health of the prisoners was exceedingly good, and this proved that excreta could be dealt with at a short distance from habitations if applied properly. The produce was consumed in the gaols, and parasitic disease did not exist.

Mr. S. WATERHOUSE, M.P., confirmed the experience of the last speaker. There was an absence of entozoa amongst the prisoners at the West Riding Prison, Wakefield, notwithstanding the fact that produce raised with manure from the gaol was consumed regularly.

Mr. W. HORE gave details as to the system of irrigation pursued on his farm of 121 acres at Romford, maintaining that his experience demonstrated irrigation to be a most successful method of utilising sewage. The quantity of sewage coming from a town with 8000 inhabitants was too great for use, and a portion was merely purified. In order to use sewage he should like an acre for every twenty persons, but to purify it a very much smaller area was necessary. The portion not used became inorganic, and therefore innocuous. The commercial success of his undertaking enabled him to pay £600 a year to the town of Romford. He ridiculed the theories as to the generation of entozoa in animals fed on irrigation lands, and said that the horse-pond was the great source of such diseases. The manure obtained by the A B C process he pronounced almost valueless.

Mr. WEBSTER, Q.C., held that there could be no question that the removal of sewage by the water system was the most economical: but there were no doubt places, such as Birmingham and Leeds, where the

irrigation system involved enormous difficulties as to the extent and distance of land, and therefore such places must consider whether there was any other practical mode of dealing with sewage. He recommended those who were anxious upon this question of public health not to indulge in extreme opinions. There could be no question that the water system was the best for removal, and that the irrigation system succeeded most completely, but surely some chemical system might be found.

Mr. MCGOWEN asked the members of the association to pause before they advocated irrigation as a remedy for every place.

Mr. RAWSON, in reply, said that the manure produced by the company cost from 30s. to 35s. per ton, and they had no difficulty in selling at £3 : 10 per ton all that they had.

Mr. SYMINGTON said that, by the process which he had explained, not only the solid portion was collected, but also the fluid.

The PRESIDENT, in closing the discussion, said that he had been sorry to hear from a member of the Leeds Corporation that he had learned nothing, and he hoped that that gentlemen would see that his means for arriving at a conclusion were very much increased by the discussion of that day. He wished, in the interest of the community at large, to urge that irrigation should be employed extensively, and in all places where it could possibly be adopted. What was the use of a Royal Commission, of the labours of a British Association, and of the Rivers Pollution Commissioners, in all cases coming to a conclusion in favour of irrigation, if they, who could not possibly go into the subject minutely to the same extent, were not to attend to the recommendations made, and say that irrigation was under the greater number of circumstances the best mode to adopt. The evidence from Mr. Blackburn's farm at Aldershot, of which he knew something, and a number of others, as at Croydon, and Mr. Hope's valuable farm at Romford, ought to induce them to say that irrigation was the best means to employ. With regard to the A B C process, he was very anxious not to say anything unfair; but he was compelled to say that its supporters said more than they could possibly prove. They said they got £3 : 10 per ton for the manure. But would they prove that it was worth this? Such chemists as he had spoken to said it was not. The expensive process which they followed could not possibly produce a manure at such a price as that manure was worth. They had not yet proved the value of it, or that the farmers would continue its use. With regard to the effluent water, which they said they were quite willing that the irrigators should have, was this effluent water sufficiently purified? It was, then, seen that sewage must be got rid of immediately, that water was the readiest means of transporting it, and that when properly disposed of on land it really did no damage whatever to surrounding persons; and all the evidence was, he thought, in favour of irrigation. He hoped the people of Leeds would look into the matter. They must no longer delay, with a thousand middens—the death-rate told them of the work that had to be done—and of the A B C process they must satisfy themselves either as to its goodness or its badness. If good, let them adopt it entirely; but if bad, then at once they must set to work to get rid of the sewage, and put it on the land around.

Friday, October 8th.

THE HABITS OF THE LABOURING CLASSES IN THE RURAL DISTRICTS.—Dr. ACLAND (Oxford) read a paper on The Sanitary Care of Villages and Cottages. He said that in well-ordered modern towns the poor had the cleansing and scavenging of the surroundings of their homes done for them. In a village or an isolated cottage, the labourer, often ill-fed, always hard-worked, must either perform this duty himself or it was left undone. The condition of the closet-accommodation in some villages and cottages was virtually inconsistent with a sense of domestic order, and was often productive of most injurious effects on the health of the family. The water was poisoned. Fevers are originated, and permanent ill-health was engendered through recurring bowel attacks. A generally untidy and miserable state of the surroundings became the habit of the family. The children grew up with these associations, having no other home-standard of decency. Many facts to show the extreme gravity of this matter in our rural districts—grave from its effects on the health of individuals—more grave, from the effect on the moral nature by engendering indifference, and on the intellectual powers by breeding ignorance and consequent false opinions on common matters. The remedy seemed to be, that, *mutatis mutandis*, the same sanitary care should be bestowed on a cottage in the country as on a house in a town. In the case of a well-ordered town the community provided water for its members, and removed their refuse for them. Not so in a village probably, in many districts, every cottage, or every other cottage, has its well, and, there being of course no sewers, its own cesspool. The expense and the risk from want of or-

ganisation were both multiplied. It might be said that our scattered populations were not worth the care, or that, if worth the care, then the supervision would in practice be too costly; so that the care of hamlets and villages was either impracticable or visionary. Issue might be joined on both these objections. The rural populations cast into the towns either a strong, decent, manly, people, or an enfeebled progeny, brought up unwisely. The immigration of the rural into the urban population was noticed on the Continent also, and was, in fact, a necessary law of modern civilisation, depending on varying causes. The case of the villages was, therefore, apart from special humanity towards the individuals, truly a national question. The great measure of last session, which undertook to harmonise into one whole all existing powers bearing on the public health, and which assigned to one minister the duty of consolidating and improving the law, wherever improvement and consolidation are needed, virtually decided the question as to what executive is to guide. With respect to the purely rural districts, the great powers of the Public Health Acts resided with vestries and guardians. In many cases, therefore, they were indirectly in the hands of the very class of persons who required guidance and help. Herein lay a great part of the strength of the Local Government Board. It enlisted in the cause of public health, understood in the widest sense, every ratepayer who voted on matters of parish organisation, and the medical men of the poor. The cottages in rural districts should be scavenged by the community, and not by the occupier. There were two ways in which this could be done: one, in villages where regular sewers and water-supply can be provided and maintained; another, in isolated cottages, where, from expense, these methods were practically inapplicable. In Broad Clyst the former has been lately tried. In Stanton Harcourt, in Oxfordshire, the latter plan had been put in operation on the dry earth system, by Colonel Harcourt, the son and successor to the venerable and scientific Canon Harcourt, owner of Nuneham. An inspector, paid by Colonel Harcourt, went weekly to the cottages on the estate to examine and report on the condition of the closets, and if they were in a bad state he removes the manure as a fine, because then the owners lost it from their gardens. The first of these methods could not pay interest on the outlay, and could only be done by persons who had capital at their command. Neither the parish nor the union could be called on to contribute to a purely local improvement, except on the principle that a great landowner must have good houses for those who till his land, the outlay being calculated as for the whole of his property; or on that principle which made the whole country pay some apparently metropolitan charges because they are part of the Imperial expenditure. On the whole, there was no doubt that an arrangement could be made in every rural district, whereby the poor labourer might have the necessary surroundings of his home kept in order for him, like his fellow artisan in the town. It would conduce to his health and energy, and it would be both just and politic, since all who believe in the existence of national health and national morality feel that the agricultural labourers deserve the utmost care of the nation.

Mr. P. H. HOLLAND had a paper on the same subject. He took precisely the same views as the Rev. Charles Kingsley, who read a paper on the condition of dwellings at the meeting of the Association in 1858.

A long and important discussion followed.

*Saturday, October 7th.*

**SANITARY QUESTIONS.**—Mr. E. CHADWICK, C.B., read a paper on the Sanitary Influences of Town Pavement. The public health was very materially influenced by the good or the defective manner in which streets were paved. Amongst the evils arising from bad pavement, he cited the escape of gases, the baneful effects of vibration on the system, caused by unevenness; the loosening of the joints of pipes, and the affording of direct means for the propagation of disease. In places where self-cleansing house-drains and sewers had been brought into good action, and where the death-rates had been reduced, but where some amount of typhoid and foul-air diseases yet lurked, these had been very much confined to those streets where the surface was unpaved and badly cleansed, and the subsoil sodden with foul matter. The Val de Travers pavement had realised more than was expected in the amendment of town pavements. It was to be wished, however, that the material were more abundant, that it might be obtained cheaper. It was to be maintained as a duty of the local authorities to provide such paving and cleanly surface conditions in the poorer districts, that there would be no mud for the children to roll in or to make mud pies of. It was for the local authorities, and in their default—the default commonly of low landlords—it was for the central authority so far to make the population as clean as might be done by cleanly surrounding pavement. Of

course a special economy was available for those districts where there was little quick carriage or horse traffic, and where the same peculiarly hard road surface was therefore not needed. Justice was not done to the Val de Travers pavement by carrying it out in isolated patches. With the new available materials, the professors of sanitary science might put these questions to urban populations:—Will you obey the command, "Wash and be clean"? will you pave so as to enable you to do so? will you pay for good paving and cleansing, to save the direct expense of filth in clothes and extra cost of washing? will you pay for good paving, to save more than half the expense of horses and carriages and the cost of transit? will you pay, in good paving and cleansing, to reduce the greater expense of the filth diseases? The time, he predicted, would come when a local administration would be tested, especially in the lower districts, by the smell of the place and by the look of the people inhabiting it.

Dr. BISCHOF, of the Andersonian University, Glasgow, read a paper on the Purification of Water and Sewage by Sponge Iron. The powers of metallic iron to purify impure water had been known for a long time. By sponge iron, he meant iron which had been produced in reverberatory furnaces by reducing an oxide without fusion. The surface was naturally greater than that of iron in any other form, and it was to be expected that its purifying action must be proportionately increased. Sponge iron could be made at a moderate cost in almost unlimited quantities from burnt ores after the copper had been extracted by the so-called chlorisation process. Water which was not thoroughly bad, but of doubtful character, might be thoroughly purified by filtering through sponge iron one foot thick, at such a rate that one cubic foot of water passed through every cubic foot of sponge iron every five minutes. Sewage might, by filtration through sponge iron, be so purified as to exhibit all the appearance of the purest drinking water. In his opinion, the action of sponge iron was twofold—chemical and mechanical. To prevent a clogging of the iron it was indispensable that the filters should be so constructed as to allow a reversion of the current of water every twenty-four hours for a few minutes. Any suspended impurity should be separated by filtration through sand or other known means before filtering through sponge iron.

Mr. T. J. DYKE sent a paper On the modes of dealing with Outbreaks of Pestilential Fevers, sanctioned by the Health Authorities of Merthyr Tydvil.

Dr. FERGUS (Glasgow) read a paper on the Production of Disease by Excremental Pollution. The reappearance of diphtheria as a disease in this country, was probably owing to our carelessness in the disposal of excreta. Typhoid fever, also (killing annually from 15,000 to 18,000), was produced by either contaminated air or water, the results of excremental pollution. He exhibited soil pipes from water-closets which were corroded by sewer gas, and which had caused typhoid fever. The principal grounds for believing that this state of the pipes arose from sewer gas, he said, were that the perforations were generally in the upper surface of the pipes, and from within; also, that in ventilated pipes the corrosive action was much slower than in pipes where the gas was not allowed to escape at the top. This state of pipes was not easily detected, as plumbers looked for liquid leakage, which would not take place, as the perforations were on the upper surface. In one case, a plumber had renewed the water-closet, but failed to detect the state of the pipes. Typhoid fever being in the house, he (Dr. Fergus) had insisted from the smell that the pipes from the closet must be corroded. He showed that cholera and diarrhoea was caused by the same carelessness in the disposal of excreta, that the decomposition took place even in the best constructed sewers, and that the result was highly detrimental to health. In large towns, the sewers were a perfect laboratory for the manufacture of sewer gas, and this gas was continually entering the houses from water-closets and sinks. He objected to irrigation, especially where the sewage was pumped—the fluid would be pumped up, but the gas would be left. Having expressed his belief in the germ-theory of disease, he said that the only true sanitary solution of the question was to provide that there should be no decomposition of excreta, that the progress of science rendered this easy, that all excreta should, either by chemical or other action, be rendered non-putrescible, and that no excreta should be allowed to enter sewers, watercourses, or rivers.

Mr. W. H. MICHAEL, referring to a statement made by Dr. Fergus, that at Croydon, in the house of Dr. Carpenter, gas had made its appearance, and that therefore decomposition took place even there in the sewers, said the system at Croydon must be judged of as carried on at its best. They must take the sewers as properly constructed and properly ventilated, and in such a way that the gas was escaping (if of necessity there were any gas, which he did not allow), and was transmitted into the air after passing through charcoal. He wanted to go back to a subject which the readers of papers persistently overlooked.

The difficulty was not how to get rid of the solid human excreta, nor even of the fluid excreta; but the great difficulty was the large amount of house-refuse which was sent into the drains. This house-refuse was acknowledged to be the difficulty, and that which, if putrescent, caused the whole of the mischief. This fluid must be dealt with; it must be taken away; it must get into the drains; and, if not dealt with, it would inevitably become mischievous and propagate disease. At Croydon, the solid constituents of the sewage were at once extracted; the works were properly constructed, and the sewage was at once put fresh upon the land, that being the initial condition of success. He maintained that the agricultural and sanitary results of irrigation were now established to be irrefutably successful.

Dr. FERGUS admitted that the system of irrigation at Croydon was perfect, but decomposition did take place.

Mr. MICHAEL objected, in vigorous terms, to general principles being argued upon exceptional cases.

Mr. E. CHADWICK said, Dr. Carpenter had informed him that the escape of gas in his house was owing to a defect of the sewer-pipe; and in every case where there had been typhoid fever in Croydon, it had arisen from a defect of the drainage. The decomposed gases came from the deposit in the drain, and if the drain had been properly constituted the deposit would have been swept away. The result of the irrigation that was carried on at Croydon was that the death-rate had been reduced from 28, and even as high as 38 in the thousand, to 16 and 17 per thousand, and it had even been as low as 14. As to the corrosion of pipes, the remedy was to employ such materials as would not corrode—earthenware or glass, for instance. Glass was made use of at Maestricht for the pipes.

Mr. B. LATHAM, the engineer of the works at Croydon, explained the operations carried on in the town to utilise the sewage. The plan was to remove as far as possible the sewage in its perfectly fresh state, the sewers having the requisite inclination to carry the matter with sufficient rapidity to the outfall, and before six hours were over the water was passed over the land and passed off again perfectly pure. From a sanitary and an economical point of view, the experiments at Croydon had established the success of irrigation. The best plan of dealing with sewage-gas was to introduce ventilators, accompanied by charcoal trays.

Mr. P. H. HOLLAND would have drawn the contrary conclusions from the facts put forth by Dr. Fergus. If it were true that all the foul matter might be washed out of the sewers, yet in practice it would be found that no work was perfect, and therefore there should be proper provision made, and soil-pipes should be ventilated.

Mr. RAWLINSON, C.E., spoke energetically in support of irrigation, and stated that the sewage could be rendered innocuous by irrigation on a much smaller extent of land than was required to utilise it thoroughly in farming.

The CHAIRMAN, in closing the discussion, commented on several points. He did not want it to go forth that in the Val de Travers pavement, without qualification, there was the material desired; and to show this he cited several defects that required consideration. He could not tolerate the notion that ventilation of sewers was not productive of decided good; and with regard to irrigation, he instanced the case of Birmingham, to show that complete utilisation was not necessary to get rid of sewage.

Monday, October 9th.

#### THE HEALTH OF OPERATIVES IN FACTORIES AND WORKSHOPS.

—In the absence of Mr. Godwin, the chair was taken by Mr. RAWLINSON, C.E. The special question for discussion was, "What are the best means of promoting the Health of Operatives in Factories and Workshops?"

The first paper was read by Dr. J. H. STALLARD, who said the question for discussion was narrowed down to what took place in the workshop. He maintained that the death-rate and the kind of disease existing proved that the air in many cases was impure. A sufficient supply of air was capable of reducing the deaths resulting from pulmonary disease; and this fact he illustrated by a reference to improvements in barracks to secure ventilation. Having contrasted the conditions under which the town artisan and the agricultural labourer pursued their callings, he contended that man was made to live in the open air, and not in a box. People who were employed in towns were obliged to be fed more expensively than they would be if isolated in cottages in the country districts. There was no doubt that a more healthy race could be produced by a less amount of expensive food than could be produced by the very best food, in large aggregations in towns and large establishments. The real stamina of the country came from the agricultural element, and that was due principally to the fact that

the labourers worked wholly in the open air. Factories and workshops should be so constructed as to assimilate the condition, as near as possible, to that of the open air, with provision only for protection against rain and violent draughts. This was all that was really required. All ventilation proceeded under the supposition that a certain amount of air was sufficient, whereas the true supply required was only to be obtained by living in the air. He exhibited a diagram of an improved method of ventilating hospitals, public buildings, and dwelling-houses; and said that if it were wanted to place workshops in free contact with the open air, the principle of numerous small openings must be adopted, and the laws of diffusion and connexion must be relied on for a sufficient and complete interchange. That was, apartments must be protected from the direct pressure of the wind, and yet a large surface must be provided with which the communication with the outer air should be free. The laws of diffusion and connection were sufficient to ensure interchange even in the stillest atmosphere, if only they had sufficient opportunity for acting; and the problem was thus reduced to the question as to the largest surface of room-sides, which might be perforated by innumerable small openings, so placed as to be free from any outside pressure of the wind. It would be expensive and difficult, and useless, to perforate the floor; but if the ceiling were perforated and protected from rain, and exposed nowhere to the direct pressure of the wind, the work-room would be placed in free, complete, and immediate contact with the outside air, and the principle of slow diffusion would have full play. No great volume of cold air could possibly be driven down on any side of the apartment, whilst the freest exit was provided for the exhalations from the lungs and body, and for any unwholesome products of the manufacture. There was no disturbance in the atmosphere of the room sufficient to interfere with the natural rising of the vitiated products to the ceiling; and in the plan he had proposed, there was nothing to prevent the escape of those products into the air-chamber, from which they were at once carried away by the horizontal current passing through. The arrangement was simple. Every room should be provided with a double ceiling, the space between being in free communication with the outer air on all sides. The top ceiling was either the floor of the room above, or the roof; the lower ceiling was made of finely perforated zinc, or oiled paper. The air-chamber should be large enough to admit of being swept out from time to time, and the sides might be made of perforated bricks of various colours and shapes. This plan did not interfere with the employment of opposite windows and ordinary means of warming rooms. The sole object was to maintain the principle of living in the open air, under all conditions, whether in winter or summer, day or night. The principle, in his judgment, was as necessary in a bed-room as in a drawing-room, and as necessary in a factory as in a hospital. It had been ignored by architects since the Roman era; but he would observe that the courts of the Pompeian house were but a more open arrangement than the one proposed. He believed that the best means of improving the health of operatives in factories and workshops would be to place them in direct communication with the open air by the plan proposed.

The REV. B. LAMPORT (London) said the principle and theory put forward by Dr. Stallard were correct, but he argued that the variations of temperature, especially at night, were such that the plan would be attended with danger in some cases.

Mr. P. H. HOLLAND held that all the benefits sought by Dr. Stallard could be got without the sacrifices proposed. As the best means of ventilating, he recommended warming the air with the waste heat before it is given off.

Mr. LEIGHTON (Liverpool) said the simplest and most effective system of heating and ventilation which he had ever seen was in a school-room at Glasgow. The whole of the exhausted air was taken away by the draught caused by a fire on the lower floor, the school being on the second floor, and the air being conveyed to the lower room in a tube from the ceiling. The supply of fresh air was by means of a perforated pipe, which pipe conveyed the air to a boiler heated by the fire, and there the air was warmed and conveyed back to the school-room.

Mr. BENNETT (Liverpool) said that the system described by the last speaker was insufficient for carrying out ventilation on a large scale, in order that that rapidity of change might be secured which was necessary. He was not quite sure that the method suggested by Dr. Stallard could be applicable in all cases; but the difference in the supply of air, he feared, did make the great difference between the health of the agriculturalist and the health of the town man.

Dr. STEWART (London) said that, by providing small perforated plates for the diffusion of the air, its introduction might be secured with very great facility.

Mr. RAWLINSON, C.E., recommended the suggestions of Dr. Stallard to the serious consideration of all persons having anything to do with men crowded either into workshops or into houses. There was no

artificial remedy, there was no fine-drawn remedy of flues or valves, or other means of that class that would give fresh air in the abundance that appeared to be necessary for health. He had been sent out by the Government to the army in the Crimea, where there was certainly room for an experiment upon the grandest scale. Our troops in the Crimea had suffered in the three months during the dreadful winter of 1854-5, at the rate of 700 per 1,000, or 70 per cent. There was starvation of various kinds—from want of necessary provisions, and from actual exposure to the elements. In the first instance, a number of huts were sent out from England, at very great cost, in lieu of tents; but these wooden houses had no sooner been inhabited than they became fever-dens and pests of the very worst kind. No instructions were given to provide isolation of each hut from the subsoil, and to provide ventilation. The side walls were eight feet high, and the roof was covered with patent felt, which was waterproof; but, unfortunately, it was air-proof too; and there being no arrangement for any ventilation at the floor, and the huts being arranged for twenty-five men, one-half of the occupants had fever. A most striking condition of affairs was found out in comparing the position of the 79th with that of the 42nd Regiment. Lord Clyde had gone with him for the first inspection, and he asked to be told the difference between the two regiments, there being very little fever amongst the 42nd, and much in the 79th. Upon investigation, he found that the encampment was on a steep mountain side, the greater part being oolitic limestone and dry, but there was a broad band of clay underneath. The 79th Regiment was on this band of clay, and the persons erecting the huts had excavated a level place into the bank of the hill-side, and consequently at the back it was three to five feet in height, sloping down at the sides; and, no provision being made to keep the earth from the sides of the huts, they were like inverted bell-receivers, with the men inside and the damp soaking in under the floor. The 42nd, on the other hand, were on the rock, and they had been compelled to raise a false floor for the huts. He advised the shifting of the regiment, and, from the time that it was shifted, the new type of disease ceased, and only the men had to recover who were originally down. The huts, however, on this band of clay were not taken down. The quarter-master forgot that they were empty. The 32nd Regiment came from India and was quartered in them, and when they had been there fourteen days there were thirty-two cases of cholera. The huts were still kept there, and, a brigade of artillery having been sent into them, within thirteen or fourteen days there were thirty or forty dead with cholera. As to day and night atmosphere, people in this country were not so much afraid of ventilation as those on the Continent. On the Continent—in France, in Germany, in Italy—there was nothing of which people were so much afraid as open windows; and the common remark if an open window were seen at night was, "There is some fool of an Englishman living in that house." There was something of the bugbear in what was said of the difference of temperature between night and day. If patients could be kept out of a direct draught, and well clothed with the bed-clothes, no harm need be apprehended. As Miss Nightingale said, what could we have but night air; and how could we injure patients by night air? There was either the atmosphere around, or an artificial atmosphere of a most abominable character. Travellers out in the East had a scorching sun on the sandy plains of Arabia, and the largest rivers were frozen over at midnight; but it was never heard that travellers there suffered from the variation of temperature; and he himself had been in a country where, during the day, the temperature in the sun exceeded 120 degrees. He had to march, with his coat off, and was perspiring from every pore. He had no shelter at night but a thin piece of cotton, and yet he saw one inch of ice on the river at night. He had always been considered a very delicate man; and although he did not say that patients could be submitted to a difference of temperature such as that, yet the human constitution would wonderfully adapt itself to circumstances if it had fresh air. Pure, uncontaminated air must be let in and out in profusion, or we could not have that health which was necessary.

Dr. STALLARD, in replying, said his system did not in the slightest degree interfere with warming a room or building. The proposal was the result of long deliberation, but it had only been matured within the last two weeks, and it had not been practically tested. He had the promise, however, that it should be fairly submitted to test. There was no danger whatever from the night air in any moderately well-placed building; provided that, for instance, in hospitals, the patient was covered up sufficiently. One medical man treated fever very successfully by taking the windows out of his building altogether; and if that was the case where the rain might beat in, what might not be expected from a system such as he had detailed?

Dr. EDDISON (Leeds) said that, in any manufacturing town, as was the case in Leeds, the air was purer at night than during the day.

Mr. G. H. L. RICKARDS read a paper on the Advantages of the

Factory Legislation that has taken place from time to time. He placed before the Section some of the more important facts connected with the working of the Factory Acts, and he also glanced at the extension of the principle to workshops. The benefits of the Factory Acts to the working classes he cited as follows:—1. Improved physical education; 2. Entire freedom from some forms of disease; 3. Increased protection from accidents; 4. Protection from excessive work; 5. Improved sanitary condition of factories; and 6. The education of all children under thirteen years of age. By the Act passed two months ago, the whole of the workshops of the country had been placed under the jurisdiction of the factory inspectors. In 1867, when it was necessary to add a large number of various trades to those already under the provisions of the Factory Acts, an Act was also passed placing all the workshops under the supervision of the factory inspectors. Their chief duties would be to prevent overwork, to see to the sanitary condition of the workpeople, and to attend to the education of all children under thirteen years of age. In this way, the whole industrial classes obtained the advantage of the supervision provided by the Legislature through the exertions of the factory inspectors.

Mr. E. CHADWICK, Dr. STEWART, and Mr. FILLITER (who had taken the place of Mr. Rawlinson in the chair) took part in the discussion on this paper, and the advantages of having medical inspection of factories were commended.

**THE WASTE OF WATER.**—Mr. P. H. HOLLAND read a paper on a cheap mode of preventing waste of water when continuously supplied. The waste of water, he said, chiefly arose from some consumers allowing many times as much water to run away as they used, with the effect commonly of making the average quantity supplied exceed three or four times (often much more) the average quantity used. The remedy proposed was to supply each house with as much water as would be fairly used, and not much more. Five gallons per individual, or twenty-five gallons per house, was considerably more than was likely to be used *per diem*; but on washing days, twice that quantity might be needed. This quantity might be supplied through a mere pin hole, discharging at the rate of two gallons an hour, and might be conveyed through a pipe a tenth of an inch in diameter, running very slowly, and therefore with very little friction. To avoid the inconvenience of having to wait for such a slow discharge, a small receptacle, large enough to hold as much as would be wanted at once, would be needed. The advantages of economising water were commented upon.

Mr. RAWLINSON, C.E., said that they could not have fine-drawn theories about water-supply. There must be water in abundance, in spite of that which theory suggested.

Mr. E. CHADWICK considered that in this case much might be learned by inquiries from persons outside the profession. He thought receptacles for the storage of water were liable to objection on account of the water losing its freshness in them.

Mr. B. LATHAM also thought the storing of water for dietetic purposes an error; and, as a means of preventing waste of water, he recommended Hall's system, to be seen at the Sanitary Exhibition.

Mr. BENNETT said that if there were a town in which, if practicable, Mr. Holland's plan could be adopted with advantage, it was Liverpool. He considered it one of the suggestions that might be worked up by engineers.

Mr. FILLITER, in closing the discussion, said that he knew no reason why any family should be allowed to use hundreds of gallons more than was needed. He did not know why water should be treated upon a different principle from bread or anything else, because in town water was a manufactured article, and a very costly article too. That the constant supply system must be adopted not only in London and Liverpool but in every large town, no one was more convinced than he was. He asked why the meter system might not be introduced under proper regulations. It was said that this system would lead people to use as little water as they could help, and thus encourage dirtiness; but it might easily be so managed that every house should pay a minimum rate, say 5s. or 10s., and should be entitled to pass through its pipe a minimum quantity, say 10,000 or 20,000 gallons. If a man consumed more, then he should pay an extra rate for the excess. The difficulty was as to the construction of the meter. But they had only to give encouragement to manufacturers to have these meters put into excellent condition. The meters were now low in price, and he thought that they would be both lower and more correct soon. Five gallons a day per head he thought too small a quantity, and his own experience of this matter suggested seven or eight gallons per head. He should let people have an ample supply of water for all reasonable purposes, and he would only exclude rigorously that abominable waste which took place in all large towns.

Tuesday, October 10th.

The Chair was taken by Dr. F. J. MOUAT.

**DEGENERACY OF RACE IN TOWNS.**—Dr. STEWART (London) on behalf of the author (Dr. H. W. RUMSEY) read a paper On the Progressive Degeneracy of Race in the Town Populations of Britain. He quoted evidence from leading journals in support of the assertion that the average physical type of Englishmen had degenerated of late years, that broad chests and powerful limbs were no longer common among labourers and artisans, and that medical examiners of recruits rejected a larger proportion every year; while those admitted into the ranks, especially of militia regiments, were very inferior in height, bone, and muscle, to their elder comrades. The author also referred to the researches of Dr. Beddoe, respecting the stature and bulk of men in these islands, and to the army recruiting returns, which concurred in showing that the rejection of recruits on account of bodily unfitness had increased from six to ten per cent. during the last thirty years; and that this degeneracy was fairly attributable, in a great degree, to the growing concentration of the working-classes in towns, to the depressing circumstances of town life, and to the large number of those engaged in indoor employment. He classed the principal influences at work in this deterioration under three heads—food and drink, labour and employment, and residence and dwellings. With regard to food, although wages had risen greatly during the last thirty years, the price of food had also increased. The cost of wholesome meat had almost doubled, and more diseased meat was sold to the poor. Vegetables were also dearer and scarcer. Ignorance of cookery and domestic economy was becoming more absolute and hopeless, as the number of women employed in manufactories increased. He cited the absence of milk in the diet of children as a main cause of sickness and constitutional debility. Measures for preventing the adulteration of food were, he said, imperatively called for. The effects of intemperance and alcoholism were cumulative; and so long as intoxicating drinks were consumed, the progeny of the drunken would be generally more feeble, vicious, and liable to disease of body and mind than their parents. The main cause of drunkenness was, he said, the house-accommodation of the poor. With regard to the effects of indoor employment, Dr. Morgan, of Manchester, had recorded his experience of the low physical condition, the bloodless, slender, and distorted forms of factory-workers in crowded populations; and he observed that this deterioration was proportioned to the length of time during which they or their ancestors had been exposed to these injurious influences. He recommended military drill as a condition of State support to elementary schools. The conditions of dwelling in our great centres of commerce and manufacture he believed to be the most destructive of all influences now at work in producing a lower type of Englishmen. The conclusions which he drew were, that comprehensive yet cautious measures were necessary for the improved accommodation of the working-classes of our great towns over larger areas of habitation; that, as for the overcrowding of persons in a house, so also for the overcrowding of dwellings on a given area, there should be a limit to density of population fixed by law, at all events in the building of dwelling-houses on fresh ground as well as in building them on ground previously occupied; and that, for the success of such measures, the establishment of a superior administrative authority, with adequate power, was as essential as it was for the execution of measures intended to prevent the adulteration and secure the good quality of food, or of those which protected labour from unhealthy conditions known to sap the vigour of the race.

Mr. J. I. IKIN agreed with Dr. Rumsey that in the large towns the lower classes of the population were falling off; but he did not think that was the case among the middle and upper classes.

Mr. E. CHADWICK asked whether the degeneracy amongst line soldiers and militia recruits was not to be accounted for by this, that as wages rose the class of men who presented themselves sank in position? He knew that this did account for it in some districts.

Mr. IKIN said that, no doubt, when trade was good, they unfortunately had very poor specimens.

**THE ROYAL SANITARY COMMISSION.**—Dr. STEWART presented the report of the Joint Committee of the British Medical and Social Science Associations as the report of the Royal Sanitary Commission.

[This Report was published in the BRITISH MEDICAL JOURNAL for August 19th.]

Mr. HARRIS called attention to a letter forwarded by Mr. Corrance, M.P., relative to this question, and to a draft of propositions which he proposed to have embodied in legislation, and suggested that they should be laid before the Joint Committee. Mr. HARRIS also proposed the adoption of the following resolution:—

"That this department approves generally of the report of the Joint Committee on the report of the Royal Sanitary Commission, to which,

for its valuable labours, much gratitude is due; reaffirms the principles embodied in the resolutions adopted at the Birmingham Congress in 1868; and expresses its regret that several of the leading recommendations of the Royal Commission are at variance with those principles by which, in the opinion of this department, the Council and Joint Committee should be guided in any representation they may address to Her Majesty's Government and the Imperial Parliament."

Mr. E. CHADWICK seconded the resolution, which, after considerable discussion, had taken place on the report (the speakers being Mr. WEBSTER, Q.C., Mr. NORTH, Dr. MARTIN, Mr. JENKINS, Dr. P. H. HOLLAND, and Dr. STEWART), was adopted unanimously.

A paper, by Mr. J. Lascelles, of Manchester, on Sanitary Law Reform, was not read owing to want of time, but it was understood that the communication would be printed in the Transactions of the Association.

**VENTILATION OF SEWERS AND SHIPS.**—A paper bearing this title was read by Dr. J. SEATON. The principle was said to be equally applicable to houses and all kinds of buildings. It consisted as regarded sewers, of the connection of a sewer with an ordinary furnace, placed outside or inside a house, the fire being only fed by air passing through a pipe from the sewer.

In the discussion, Mr. R. SYMINGTON (Glasgow), Dr. SYSON, Mr. E. CHADWICK, Mr. BENNETT, and Mr. FILLITER took part. Mr. FILLITER said that it was his experience that where there was a current of water in a self-cleansing sewer there was a current of air in the same direction; and he pointed out that the great difficulty to be contended with in ventilation was when the sewers became surcharged with water, and there was no room left for the gases, which made their escape by breaking through the traps.

**COTTAGE HOMES.**—Mr. W. G. HABERSHON, F.R.S., read a paper on Cottage Homes, illustrative of the manner in which the Central Cottage Improvement Society of London had laboured in providing improved dwellings for the working classes. The object of the Society had been to assimilate the cottages as nearly as possible to cubical form, and to take out everything unnecessary, so as, in reducing the size, to reduce the cost also. Plans and models were exhibited, showing the different developments of the leading idea. A pair of cottages with three bedrooms cost from £200 to £225—a single cottage £100. A triple cottage containing separate dwellings respectively of three, two, and one bedrooms, under one roof, cost £300 under ordinary circumstances, and was convertible to village school, cottages, hospital, or single superior dwelling. Cottages suitable to miners or for towns, in groups of three or more, had been suggested by the Society to cost less than £100 each cottage. The general principles to be observed in building good cottages were enumerated.

**SCHOOLS.**—Mr. E. CHADWICK read a paper on The Sanitary construction of Schools. Schools, as at present constructed, were the centres of children's epidemics. An excess of 50,000 deaths annually in England and Wales in the school stages of life, medical officers had agreed with him, was largely due to the massing of unwashed children together in ill-warmed and ill-ventilated schools, and to keeping them during long hours together under those conditions. The increase of these masses, without regard to those conditions, was an augmentation of preventable disease and premature mortality. Bad ventilation was augmented by bad warming. He advocated, in preference to other methods, a return to the Roman plan of warming rooms by hypocaust floors; or an adoption of the Chinese method of floor-warming, which travellers declared the most comfortable of any they had ever experienced. It was also the most economical. As one mode of effecting the object, he had proposed a form of tile with labelled or lock joints (with a species of supports) to be made of selenite, or Portland concrete, or pottery. By these appliances, hollow floors might be constructed at an expense no greater than that of common floors. Experience showed that when the children could be kept warm, doors and windows might be more freely opened. Every school should have the means of washing with tepid water children who came dirty.

Several other papers—the contributors of which were Mr. J. D. Morrison, Dr. J. T. Arlidge, and Dr. C. Slagg—were held as read. Dr. Arlidge had a paper on the Health of Operatives in Factories and Workshops. The paper was based on statistics derived from the outpatient practice of the North Staffordshire Infirmary, Stoke-on-Trent.

**SANITARY CONDITION OF LEEDS.**—Dr. ROBINSON, the Medical Officer of Health for Leeds, read a paper on the Sanitary Condition of Leeds. He described the organisation of the town in regard to registration, and the mode of obtaining returns of the mortality. The Sanitary Committee of the Town Council in discharging its duty as prescribed by the Sanitary and Nuisances Removal Acts had, for the purpose of securing systematic inspection, cottage house-to-house visitation, and the adoption of general hygienic proceedings, divided the borough

into fifteen divisions, to each of which an inspector was assigned, whose duty it was to ascertain and report daily in writing whatever nuisances he might find in his district to the chief inspector of nuisances, under whose control and supervision the several inspectors were placed. These men also reported particulars of zymotic cases on printed forms to the officer of health, and performed a number of duties under his direction. In eight of the fifteen districts nearly the whole time of the inspectors was devoted to sanitary work. In these eight divisions, which include the central part of the town, the area traversed averaged 1,000 acres per man, the population equal to each being about 20,000. In the seven remaining suburban divisions the men devoted only one day per week to sanitary duty, with one exception, where two days were set apart for that purpose. The area of each subdivision averaged about 1,800 acres, and the population in each numbered about 5,000. From January 1867, to September 30th of the current year, 51,131 notices and letters were sent out, 351 summonses issued, and penalties for sanitary offences amounting in the aggregate to £288 : 14 : 6 inflicted (exclusive of smoke penalties). Through the help of this preventive staff diseases were often traced to their causes, and timely remedies were applied to arrest their progress. In scores of instances, typhoid fever had been traced to either defective drains, or excrement-polluted soil and water; and the removal of the discovered evils had been followed by suppression of the disease. During the cholera epidemic of 1866 this malady never extended to the population of Leeds, although introduced into one of the courts by a gang of railway workmen, who came direct from an infected house in Liverpool; prompt conjoint action by the Leeds Town Council and the Board of Guardians (consisting in perfect isolation of the sick and segregation of the infected from the rest of the inhabitants of the town, etc.) being at once taken on the outbreak of the disease. Then, during the epidemic of relapsing fever last year, that disease never became so widely diffused in Leeds in relation to the population as in many other towns, although introduced seventeen times; the measures adopted being early removal of the sick from the healthy, accompanied by disinfection and cleansing of infected houses, clothing, etc.; and, up to the present period of this year, with smallpox widely diffused through the country, there had been only nineteen deaths from the disease in Leeds, although since January it had been introduced seventeen times. Beds and woollen garments, etc., which were not destroyed, were disinfected in the Corporation's own apparatus. The merit of calling public attention to the value of dry heat as a disinfectant, as practised years ago by Dr. Henry, of Manchester, was due to Dr. Shann, of York, who read a paper on the subject in this section in the year 1864. In addition to the work just described as being done, the Leeds Town Council had obtained powers of its own to deal with faulty property, compensating the owners thereof for loss. Beginning in the heart of the town, the Corporation had already decided to destroy one whole block of buildings, consisting of sixty houses, and covering a space of 2,505 square yards. The Council were about to be further asked by the Sanitary Committee to adopt a similar scheme for clearing away two blocks of streets and courts, where in one instance the death-rate had averaged during the last five years 50.3 per 1,000 *per annum*, and in the other during the same period 68.2 per 1,000 *per annum*, embracing in the first case twelve courts, and involving the destruction of 163 houses, covering about 8,640 square yards, and in the second the demolition of twenty-eight houses. The Sanitary Committee, in deciding upon this wholesale demolition of property, had not been guided by the death-rate of the locality alone, but had been influenced by other reasons, viz., that the localities in question had been the principal seats of every epidemic that had visited the town, and further that the faulty arrangement of the houses as to construction, ventilation, out-office accommodation, surroundings, etc., was such as to preclude any other remedy than total demolition. The rate of mortality of Leeds was so often misquoted as increasing in intensity year by year that it was necessary to show that in this respect also improvement had taken place. The actual death-rate of the last five years, counting the three-quarters of the current year just expired, had only averaged 27.1 per 1,000 *per annum*, compared with 31.3 as the average of the preceding five years. The death-rate of the current year, from January 1st up to last Saturday night, was 26.7 per 1,000 *per annum*; so that Leeds, in its diminished mortality, compared favourably with the past. Leeds, therefore, with its magnificent waterworks, in course of construction; the improved docks; undertakings for demolition of noisome courts and pestilence-breeding houses; its recent decision to abolish barbarous middens; its sanitary organisation and persistent administration of the Sanitary and Nuisances Removal Acts, accompanied with a diminished death-rate, might fairly be said to be making material progress in sanitary improvement, and this in the face of enormous difficulties, such as viciously constructed houses, interested associations organised for the purpose of stemming

the stream of sanitary reform, and a Chancery injunction causing sewage-logged houses, and necessitating cesspools for all new buildings. Since Dr. Robinson's connection with the Leeds Corporation no chief magistrate had taken a livelier interest than the present in the sanitary welfare of the people, and the chairman of the Sanitary Committee devoted nearly all his time and abilities day after day to the amelioration of the evils which called for removal. The display of this zeal and assiduity on the part of those placed in positions of trust and responsibility he took as indicating a determination on the part of her rulers that, as Leeds was one of the first towns in the kingdom to inaugurate a system of preparing reports upon the sanitary condition of massed populations, so now, by a practical solution of various sanitary problems, she shall again take front rank and lead other towns in the "way of life."

Dr. STALLARD, in commenting on the paper, advocated the registration of infectious diseases, and pointed out that two-thirds of the cases brought under the notice of Dr. Robinson occurred in houses which were built next to the middenstead. He denounced the back-to-back system of building houses, especially as it rendered it absolutely essential that the middenstead should be built, as it were, in and among the houses, and he recommended that for the future no midden should be erected in contact with the walls of a house. He insisted most strongly that the sewer should be ventilated, and he urged that vacant spots should be preserved, or created if they did not already exist, in the crowded parts of the town, on which in times of epidemic sufferers might be treated in hospitals, and at other times children might play.

Mr. E. CHADWICK approved of maps being kept to shew the spots affected by epidemics. He commended for application the code of regulations on the duties of medical officers issued by Lord Ashley, Dr. T. Southwood Smith, and himself in 1851.

Mr. SYSON (Salford) indicated what is being done in Salford to provide for the health of the town. One plan he suggested for imitation—every passage to communicate with the street at each end, and every home to have a separate convenience.

Mr. P. H. HOLLAND said that when people were displaced from their dwellings there was the evil to be guarded against of the remaining buildings being overcrowded. Why should not the owners of demolished houses be repaid in other houses suitable for the same class of population? As houses could be put up at £80, it did not appear impossible to do this without much loss. It would be worth while for a Corporation to make the experiment. Might not employers of labour take up the question and provide dwellings out of their capital? The employer might always have his houses let, and he would be able to bring down the excessive rent of other houses.

Dr. FERGUS (Glasgow) referred to the large number of deaths amongst children under five years of age, and said that, although for a large proportion of such cases medical attendance was provided, the people displayed manifest carelessness in Leeds.

Dr. STEWART was gratified to hear the report of Dr. Robinson. The mode adopted in Bristol with regard to the inspectors was a particularly good one. There were four chief inspectors, each with five men under him, and controlled by him. Every morning they had a meeting with the Medical Officer of Health. The sanitary inspectors should all be controlled by the Medical Officer of Health and responsible to him, and they should cease to have police duties.

Mr. W. BOTLY (Salisbury) stated that by the system of drainage brought into operation in that town the death-rate had fallen from 27 to 16 per 1000. Property had increased very much in value.

Mr. Councillor T. MOSLEY had been a supporter of the reforms now being carried out by Dr. Robinson for many years, and he wished the Association to understand that the people of Leeds had more knowledge of these sanitary matters than the members supposed. Dr. Robinson had been simply reiterating what he (Mr. Mosley) had done year after year.

Mr. FENWICK (Leeds) said that the Council had done a great deal of late for the improvement of the town, and within the last four years had spent £120,000 in widening streets and opening up new thoroughfares. They were now about to enter upon a great work of clearing away the overcrowded dwellings of the poorer classes in the heart of the town. There was one thing, however, which the Town Council might do with great advantage, and that was, whilst sweeping away in the overcrowded districts, to take a little more care to preserve better ventilation in the new buildings being erected for the working classes. There could not be proper ventilation if they went on building up a town and extending its suburbs by absorbing all the space for dwellings. If through ventilation could be got, so much the better. He had always condemned the principle of back-to-back houses; and he thought that each house ought to have a convenience.

Dr. ROBINSON replied, and mentioned that the scheme of Dr. Stallard had his entire accord.

## ASSOCIATION INTELLIGENCE.

## COMMITTEE OF COUNCIL: NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the Queen's Hotel, Birmingham, on Tuesday, the 31st day of October, 1871, at One o'clock *precisely*, to elect a Secretary, and for other important business.

T. WATKIN WILLIAMS, F.R.C.S., *General Secretary* (pro tem.)  
13, Newhall Street, Birmingham, October 17th, 1871.

## BATH AND BRISTOL BRANCH.

THE first ordinary meeting of the Session will be held at the York House, Bath, on Thursday evening, October 26th, at seven o'clock: CROSBY LEONARD, Esq., President.

R. S. FOWLER, Bath, } *Honorary Secretaries.*  
E. C. BOARD, Clifton, }  
6, Belmont, Bath, October 1871.

## CUMBERLAND AND WESTMORLAND BRANCH.

THE autumnal meeting of the above Branch will be held at the King's Arms Hotel, Wigton, on Wednesday, October 25th, at half-past twelve o'clock. The President, Dr. ELLIOT of Carlisle, will occupy the Chair.

Gentlemen intending to read papers or cases, are requested to communicate with the Secretary at their earliest convenience.

HENRY BARNES, M.D., *Honorary Secretary.*  
Carlisle, October 3rd, 1871.

## SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT MEDICAL MEETINGS.

THE next meeting of this Society will be held at the White Hart Inn, Reigate, on Thursday, October 26th. The Chair will be taken by Dr. HOLMAN, at 4 P.M.

Dinner at 6 P.M. Charge 5s., exclusive of wine.

Papers, etc., are promised by Dr. Holman, Dr. Phillips, Dr. Walters, Mr. St. A. Hawken, etc.

HENRY T. LANCHESTER, M.D., *Honorary Secretary.*  
Croydon, October 13th, 1871.

## SHROPSHIRE SCIENTIFIC BRANCH.

THE annual meeting of the members of the above Branch will be held in the Museum, Shrewsbury, on Friday, October 27th, at 2 o'clock: Dr. J. W. MOORHOUSE in the Chair.

Several papers have been promised; and some photographs and interesting preparations will be exhibited.

Gentlemen intending to contribute, are requested to communicate with the Honorary Secretary.

The dinner will take place at the Lion Hotel at 4.30. Members intending to dine or introduce friends, are requested to send in their names not later than the 24th instant.

SAMUEL WOOD, F.R.C.S., *Honorary Secretary.*  
Shrewsbury, October 10th, 1871.

## BIRMINGHAM AND MIDLAND COUNTIES BRANCH: PATHOLOGICAL AND CLINICAL SECTION.

THE annual meeting of the Section will be held on Friday, October 27th, at the Birmingham and Midland Institute. The Chair will be taken at 3 P.M.

BALTHAZAR W. FOSTER, M.D., } *Honorary Secretaries.*  
T. VINCENT JACKSON, }  
Birmingham, October 18th, 1871.

## SOUTH WALES AND MONMOUTHSHIRE BRANCH: ORDINARY MEETING.

THE next Ordinary Meeting of this Branch will be held on Tuesday, November 7th, at the Town Hall, Cardiff, at 1.30 P.M. The Council will meet at 12.30 P.M.

The Dinner will take place at 5.30 P.M.; and members may introduce professional friends to the meeting and dinner.

Members intending to read papers or notes of cases are requested to communicate the titles thereof as soon as possible to one of the Honorary Secretaries.

All members who purpose joining the dinner, will oblige by communicating their intentions to one of the Honorary Secretaries before the 31st instant.

ANDREW DAVIES, } *Honorary Secretaries.*  
ALFRED SHEEN, M.D., }  
October 4th, 1871.

## REPORTS OF SOCIETIES.

## CLINICAL SOCIETY OF LONDON.

FRIDAY, OCTOBER 13TH, 1871.

WILLIAM W. GULL, M.D., D.C.L., President, in the Chair.

*Idiopathic Pericarditis.*—Dr. BÄUMLER read a paper on Partial and General Idiopathic Pericarditis, in which he endeavoured to prove that the white or milky spot on the surface of the heart frequently met with at *post mortem* examinations has a clinical history of very transient acute pericarditis. He adduced in support of this proposition two cases, in which an acute illness, coming on with dyspnoea, with pain behind the sternum, radiating upwards to the larynx, the left shoulder, and towards the left ear, and with slight febrile disturbance, was accompanied by a characteristic pericardial friction-sound, lasting, like the other symptoms, only for two or three days. In a third case, where the onset had been more gradual, the friction-sound was heard over a larger area; and there was also some distension of the pericardium by fluid; yet the whole attack was mild and lasted only a fortnight. Such intermediate forms link the very slight cases to the more serious ones, which more generally come under observation. Cases of idiopathic pericarditis being of rare occurrence, Dr. Bäumlér appended the history of three other cases of this kind which had come under his observation. The three patients were little girls from eight to ten years of age, and the pericarditis had come on in so insidious a manner that they had walked about with the pericardium full of effusion. One of them died; the two others recovered, one entirely, the other with valvular disease remaining. With regard to treatment, Dr. Bäumlér particularly recommended the application of ice to the cardiac region, especially for its influence in reducing the number of the heart's contractions and in relieving pain.—The PRESIDENT, in suggesting some points in the paper for discussion, alluded to the doubts which had been expressed by some of the greatest observers, as to whether pericarditis *per se* caused pain, and this opened up the question whether the cases before the meeting were instances of pericarditis. Amongst the fallacies of the stethoscope is that of the to-and-fro murmur. It would be interesting again, he continued, to discuss, what are the idiopathic conditions which set up pericarditis.—Dr. BÄUMLER, in answer to Dr. Douglas Powell, said he employed mustard and linseed-meal empirically to relieve pain, and ice to reduce the rapid action of the heart, and as an antiphlogistic.—Dr. POWELL alluded to friction-murmurs coming on in acute fevers and going off in a few hours, the occurrence of which, he supposed, might be due to the dryness of the pericardium.

*Erythematous Lupus.*—Mr. NUNN read a paper on Lupus Erythematous. This disease, known also as superficial lupus, was believed by Mr. Nunn to be essentially an inflammatory atrophy of the cutis, limiting itself to that structure, and thus distinguished from lupus exedens, which was capable apparently of destroying indiscriminately every structure. Two cases of lupus erythematous were reported, in which the family history afforded no clue to the nature of the disease; and, in contrast, one case of lupus exedens, in which an hereditary syphilitic taint was with almost complete certainty to be traced. The first two cases had been treated for years before coming under Mr. Nunn's care with mercury, iodine, arsenic, etc. The first patient, a male, aged 34, had (October 1870) suffered during thirty-two years, the second during twenty-one years, with lupus erythematous of the cheek. The bromo-iodine water of the Woodhall Spa, in doses of a wineglassful three times a day, was given, and a table spoonful of lemon-juice in a tumblerful of milk every morning. In the first case, the gums being spongy, a solution of chloride of zinc (one grain to the ounce of water) was ordered to be applied to them. This case was to all appearance cured at the end of six months. The second patient was still continuing the treatment with advantage, having only commenced it in May last. The case of lupus exedens had been in the Middlesex Hospital under the care of the late Mr. Moore, and was now an inmate of the Hospital for Incurables at Putney.—Dr. ALTHAUS pointed out the resemblance of the Woodhall and Kreuznach waters, and, in the course of some further remarks, expressed his opinion that, in strumous affections, iodine is too freely prescribed.

*Melanotic Tumour of the Eye.*—Mr. G. LAWSON related the particulars of a case of large melanotic tumour of the eye, which had burst through the sclerotic and had extended into the orbit. He first excised the globe, and then freely applied the chloride of zinc paste for the purpose of destroying all the tissues within the orbital cavity, and thus effectually getting rid of all the cancer-germs with which those structures are in such cases generally infiltrated. The operation was performed in July of this year, and the patient was now progressing favourably to-

wards recovery. All the tissues within the orbit sloughed, and large portions of the bony cavity exfoliated. Mr. Lawson remarked that, when the diagnosis of melanotic tumour within the eye is made at a very early stage of the disease, the simple removal of the eye is frequently sufficient. He quoted the case of a patient in whom he had been able to recognise the tumour by the ophthalmoscope when it was scarcely of the size of a pea. He removed the eye, and now nearly three years have elapsed, and there has been no recurrence of the disease in the orbit.—Mr. DE MORGAN expressed the opinion that the caustic might be applied with advantage, even in the early stage of the disease after removal of the eyeball. In a case alluded to by the author of the paper, he believed life might have been prolonged had this been done. He had observed epileptiform convulsions occur immediately after the application of the caustic on more than one occasion. In reply to Dr. Buzzard, he stated, however, that they did not recur.—Mr. LAWSON remarked that his patient had presented similar cerebral symptoms after the operation.—The PRESIDENT, in alluding to the advantages of early removal, referred to a case in which a melanotic affection of the eye had been removed nine years ago, and in which the disease had not returned until eighteen months ago. He wished that cancer always attacked the eye, as it could then be seen and removed early.—A long and interesting discussion was here awakened by a remark of the President on the local origin of cancer, and an expression of disbelief in the generally accepted meaning of the term constitution. The question of a swollen gland arresting disease was discussed. It was pointed out by Mr. De Morgan that cancer spreads from gland to gland as from the original growth to a gland. In scarcely an instance, he said, does it happen that the part which ought to be most prone to disease, on the constitutional theory of cancer, becomes affected in recurrences, as, for example, in the case of the mamma.—Mr. LAWSON further pointed out that family history was rare in cancer, as shown in the Reports of the Registrars of the Middlesex Hospital.—Mr. ARNOTT, however, expressed his belief that the recurrence of cancer in the remaining mamma, although very rare, was more frequent than thought to be by Mr. De Morgan.—Mr. Henry Lee, Mr. Nunn, and others, also joined in this discussion, which closed the proceedings of the meeting.

## CORRESPONDENCE.

### MIDDLESEX AND UNIVERSITY COLLEGE HOSPITALS.

SIR,—With reference to an article in another medical journal of October 14th, headed "University College Hospital", I beg leave to state that students from University College are only admitted to the medical and surgical practice of the Middlesex Hospital on exactly the same terms, with regard both to fees and privileges, as other occasional students who may enter for hospital practice, no preference whatever being given to the students from University College over such other occasional students with respect to clinical appointments, for which they are only eligible in the event of no general pupil of Middlesex Hospital Medical College offering himself.

The notice in the prospectus of University College, of which mention is made, refers to matters of private arrangement between the authorities and students of University College itself, with which the staff of the Middlesex Hospital are in no way concerned, and of which they had not even been made cognisant.

With regard to the advantages which the writer of the article intimates this hospital would derive from the supposed agreement, by being thereby enabled to fill up its clinical appointments, I may be permitted to state that for these appointments the large field for practical study afforded by the Middlesex Hospital has never yet failed to secure an ample supply of eligible candidates.

I am, etc.,

W. CAYLEY, M.D.,

Dean of the Middlesex Hospital Medical College.

Oct. 16th, 1871.

## UNIVERSITY INTELLIGENCE.

### UNIVERSITY OF OXFORD.

NATURAL SCIENCE FELLOWSHIP.—Mr. Walter William Fisher, B.A., Postmaster of Merton College, has been elected to the vacant Natural Science Fellowship at Corpus Christi College, the examiners for which (Dr. Odling and Mr. A. Vernon Harcourt) made honourable mention of Mr. Christopher Childs, of Merton College. Mr. Fisher was placed in the first class in Natural Science in Trinity Term, 1870, and Mr. Childs gained a similar distinction in Michaelmas Term, 1870.

### UNIVERSITY OF CAMBRIDGE.

EXAMINERS.—Mr. C. Trotter, of Trinity College, and Mr. W. P. Hiern, of St. John's College, have been appointed examiners for the first M.B. examination; Mr. John Wood and Dr. Bradbury for the second M.B. examination; and Dr. J. W. Ogle and Dr. H. Davies for the third M.B. examination. Mr. C. Lestourgeon, and Mr. G. W. Callender, F.R.S., have been appointed examiners for the degree of Master in Surgery; and Dr. Barclay has been appointed Assessor to the Regius Professor of Physic.

Dr. MICHAEL FOSTER has been elected to a Fellowship at Trinity College. Dr. Foster was recently appointed Prelector in Physiology at the College.

## MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At an extraordinary meeting of the College, on Monday, October 16th, the following was admitted a Fellow.

Waring, Edward John, M.D.St. And., Clifton Gardens, Maida Vale

The following gentlemen, having conformed to the by-laws and regulations, and passed the required examinations, were granted Licences to practise Physic, including therein the practice of Medicine, Surgery, and Midwifery.

Biddle, Cornelius, M.R.C.S., Queen's Road, Dalston  
Davies, Henry, M.R.C.S., Pentreth, Morriston, Swansea  
Eager, Wilson, M.R.C.S., Bethlehem Hospital  
Edmonds, Frederick H., M.R.C.S., University College Hospital  
Hobley, Simon Halford, M.R.C.S., Queen's Crescent, Haverstock Hill  
Newington, Frank E., M.R.C.S., Evering Villas, Amhurst Road, Hackney  
Scully, John, M.R.C.S., Middlesex Hospital  
Stamford, William, M.R.C.S., Tunbridge  
Thomas, John Howell, London Hospital  
Wall, William Barrow, University College Hospital  
West, John G. U., M.R.C.S., University College Hospital  
Wilby, John Burdett, M.R.C.S., Leicester

The following candidates, having passed in Medicine and Midwifery, will receive the College Licence on their obtaining qualifications in Surgery recognised by the College.

Bland, George, St. Bartholomew's Hospital  
Harries, Thomas Davies, Guy's Hospital

APOTHECARIES' HALL.—The following gentleman passed his examination in the science and practice of medicine, and received a certificate to practise, on Thursday, October 12th, 1871.

Masterman, George Frederick, Croydon

The following gentlemen also on the same day passed their first professional examination.

Bowkett, William David, London Hospital  
Grogono, Walter Atkins, London Hospital

### MEDICAL VACANCIES.

THE following vacancies are announced:—

AMERSHAM UNION, Bucks.—Medical Officer for the Chesham District.  
CHARING CROSS HOSPITAL.—Assistant Physician.  
COUNTY WICKLOW INFIRMARY.—Apothecary.  
DEVON COUNTY LUNATIC ASYLUM.—Assistant Medical Officer.  
DORCHESTER UNION.—Medical Officers for the Dorchester District and the Workhouse.  
ENNIS UNION, co. Clare.—Medical Officer for the Newmarket-on-Fergus Dispensary District.  
EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge Road.—Surgeon.  
GENERAL HOSPITAL, Nottingham.—Resident Surgeon-Apothecary; Assistant House-Surgeon.  
GORT UNION, co. Galway.—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Ardahan Dispensary District.  
GREAT NORTHERN HOSPITAL, Caledonian Road.—House-Surgeon.  
INFIRMARY FOR CONSUMPTION AND DISEASES OF THE CHEST, Margaret Street, Cavendish Square.—Visiting Physician.  
LONDON FEVER HOSPITAL.—Physician.  
LOUDOUN, Ayrshire.—Parochial Medical Officer.  
MALE LOCK HOSPITAL, Dean Street, Soho.—Resident House-Surgeon.  
METROPOLITAN DISPENSARY, Fore Street.—Surgeon.  
NORTH UIST, Inverness-shire.—Parochial Medical Officer.  
OMAGH UNION, co. Tyrone.—Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Eastern Division of the Omagh Dispensary District.  
PRESTON AND COUNTY OF LANCASTER ROYAL INFIRMARY.—Two House-Surgeons.  
ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road.—Surgeon.  
ROYAL SURREY COUNTY HOSPITAL, Guildford.—House-Surgeon.  
ST. GEORGE'S DISPENSARY, Mount Street, Grosvenor Square.—Physician-Accoucheur.  
SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.—Assistant House-Surgeon.  
SWAFFHAM UNION, Norfolk.—Medical Officer for the Saham Toney District.  
TYRIE, Aberdeenshire.—Parochial Medical Officer.

WALSALL UNION, Staffordshire—Medical Officer for the Workhouse.  
 WESTHAMPTON UNION, Sussex—Medical Officer for the Rumboldwhyke District.  
 WEYMOUTH UNION, Dorset—Medical Officer and Public Vaccinator for the Melcombe Regis District.

## OPERATION DAYS AT THE HOSPITALS.

MONDAY .....Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
 TUESDAY .....Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
 WEDNESDAY...St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
 THURSDAY ....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
 FRIDAY .....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.  
 SATURDAY....St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—Medical Society of London, 8 P.M. Adjourned discussion on Mr. Gay's paper on "Crural Venosity." Communications by Mr. Spencer: 1. Traumatic Dislocations of the Crystalline Lens; 2. Congenital Displacement of both Crystalline Lenses; 3. A Convenient Method of Applying Cold to Inflamed Parts. Mr. John Pennefather, "On the Physiology of Sound, with Illustrations."  
 TUESDAY.—Royal Medical and Chirurgical Society, 8.30 P.M. Mr. J. W. Haward, "On Ether and Chloroform as Anesthetics"; Mr. F. Le Gros Clark, "Case of large Biliary Concretion in the Ileum."  
 FRIDAY.—Quekett Microscopical Club (University College, Gower Street), 8 P.M. Mr. T. Charters White, "On the Microscopical Structure of the so-called 'Nerve' of a Tooth."—Clinical Society of London, 8.30 P.M. Dr. C. T. Williams, "Cases illustrating the Contraction of Cavities in Phthisis"; Dr. John Murray, "On a Case of Paracentesis Thoracis"; Dr. Anstie, "The continuation of a Case previously reported"; and other papers.

## NOTICES TO CORRESPONDENTS.

ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

TO PURCHASERS.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with halfpenny stamps for the amount.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

Dr. SHAFER (Exeter), Dr. HITCHMAN (Mickleover), and Dr. ENGLISH MACKENZIE (Sedburgh), shall receive early proofs.

ORDERS to press on our space, many letters and communications are postponed.

Dr. THOMSON (Oxford).—With great pleasure.

Dr. CHAMBERLAIN (Nase).—Many thanks.

Dr. NICHOLSON (Torquay).—Many thanks. Is the point mentioned one of any real importance? We are disposed at present to enquire with the view of the Committee of the Charity Organisation Society; but should be glad to be informed of the objection to it, and on what they are based.

Mrs. B. C. Thanks for your note, which came, however, too late for use.

PHYSIOLOGY OF DIGESTION.

Sir, Can you, or any of your correspondents, inform me where I can find any diagrams, portraits, etc. illustrating the "physiology of digestion." A few were published by Fox & Co. in the Medical Times and Gazette for 1871, but I have not met with any since. I am, etc., C. J. EVANS, Northampton, October 15th, 1871.

Mr. R. W. PARKER (London).—It shall appear as early as possible.

W. S. BROWN.

Sir, Some three weeks since, a man came to me suffering acute pain in the left thumb, he had been previously stung by a wasp under the nail. Concluding that the poison was of an animal nature, I immediately applied some strong hydrochloric acid, with very great benefit, and on introducing my anæsthetic, by means of a needle, into the minute opening, the pain was completely relieved and the sting cured. I am, etc., GEORGE H. CRAVED, M.D. Stafford, October 15th, 1871.

NOTICE TO ADVERTISERS.—Advertisements should be forwarded direct to the Printing-Office, 37, Great Queen Street, W.C., addressed to Mr. F. H. HEATHCOTE, not later than Thursday, twelve o'clock.

We are greatly indebted to Dr. Gibb and Dr. Page (Newcastle-upon-Tyne) for the favour of the documents which they have forwarded.

DR. DOBELL AND THE BRITISH AND FOREIGN MEDICO-CHIRURGICAL REVIEW.  
 SIR,—Although I never interfere with the privilege of reviewers to be as fair or as unfair as they please in their representations, it is, I believe, quite in order to correct an actual misstatement of facts. May I, therefore, ask you to allow me a few lines in which to call attention to an instance of this in the review of my "Reports on the Progress of Medicine, 1870," published in the current number of the *British and Foreign Medico-Chirurgical Review*.

After pluming himself upon "our usual course of honest criticism," the reviewer says: "We cannot let pass one breach of promise in the announcement of the character of the work, and of which no notice is taken in the present preface; viz., the non-fulfilment in some instances of the condition that the Reports should be written by distinguished men resident in the countries which they represent. It may be, readers have not lost much by some of the reports on the progress of medicine in foreign lands being allotted to gentlemen resident in England; but the promise made, implied that Dr. Dobell considered it a recommendation of his undertaking, that reports should come from physicians resident in their native countries, and presumably better acquainted with the literature, teaching, and practice there in vogue, than non-residents could be. So far, therefore, it is to be regretted that Dr. Dobell made an engagement without means to fulfil it."

Now, sir, to show the absurd misstatements in this extraordinary passage, it will be only necessary to enumerate the contents of my volume to which it refers.

Contents of vol. ii, 1870.

America.—Report by Dr. Carroll of New York.

Australia.—Fragmentary Report, composed entirely of Materials furnished by Drs. Halford, Bird, and Thompson, of Melbourne.

California.—Report by Dr. Logan of Sacramento.

China.—Report by Dr. Porter Smith of Hankow.

France.—Report by Professor Villemin of Paris.

Germany.—Report by Dr. Althaus of London.

Iceland.—Report by Dr. Hjalatalin of Reykjavik.

India.—Report by Mr. Macnamara of Calcutta.

Italy.—Report by Dr. Sammut of Naples.

Java and Madura.—Report by Dr. Wylie of Batavia.

Newfoundland.—Reports by Dr. Anderson of Brigus and Dr. Crowdy of St. John's.

New Zealand.—Reports by Dr. Kemp of Wellington and Dr. Tassell of Auckland.

Portugal.—Report by Dr. Brandt of Oporto.

Prince Edward Island.—Report by Dr. Hobkirk of Charlotte's Town.

Shetland.—Report by Dr. Saxby of Baltasound.

Turkey.—Report by Dr. Sarell of Constantinople.

United Kingdom.—Reports by two gentlemen resident in Ireland, two in Scotland, and nine in England.

General Report on Mechanical Appliances, etc., in all parts of the World. By Mr. Heather Bigg of London.

It will be seen that in the whole volume, the only exception to the rule that the reports should be written by men "resident in the countries which they represent," is the case of Dr. Althaus; and of his report, the reviewer is obliged to admit that "The notice of Germany, although not written by a physician resident in Germany, according to the strict letter of Dobell's advertisement, comes from the very competent pen of Dr. Althaus, who is well versed and interested in the literature of the fatherland."

I think, sir, I need not say more to expose the worthlessness of such reviews as the one in question, which is by no means an isolated example. It is certainly time that the editor of the *British and Foreign Medico-Chirurgical Review* selected better tools with which to do his important work.

October 1871.

I am, etc., HORACE DOBELL, M.D.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Brighton Herald, Sussex, Surrey, Kent, and Hampshire Advertiser, Oct. 14th; The Wolverhampton Chronicle, Oct. 18th; The Altrincham and Bowden Guardian, Oct. 14th;

COMMUNICATIONS, LETTERS, ETC., have been received from:—

Dr. W. B. Cheadle, London; Dr. J. C. Hall, Sheffield; Mr. Simon, Blackheath; Mr. T. Charters White, London; Dr. T. Clifford Allbutt, Leeds; Dr. William Roberts, Manchester; Dr. J. D. Heaton, Leeds; Dr. Smart, Penge; Mr. George Lawson, London; Mr. R. W. Parker, London; Miss Morgan, M.D., London; Mr. S. G. Sloman, jun., Farnham; Dr. J. Hughlings Jackson, London; Dr. A. P. Stewart, London; Dr. R. W. Crighton, Tavistock; The Secretary of the West Kent Medico-Chirurgical Society; Dr. Robert Grieve, London; Mr. Henry Harden, St. Mawes, Cornwall; Dr. Lanchester, Croydon; Dr. Cayley, London; Dr. Page, Newcastle-upon-Tyne; Dr. Gibb, Newcastle-upon-Tyne; Dr. Robert Farquharson, Vienna; Dr. E. L. Fox, Clifton, Bristol; Mr. T. H. Bartlett, Birmingham; Dr. J. W. Ogle, London; Dr. Alfred Meadows, London; M.R.C.S.; The Registrar-General of England; The Secretary of Apothecaries' Hall; The Registrar-General of Ireland; Mr. T. M. Stone, London; The Registrar of the Medical Society of London; Dr. Mapother, Dublin; The Secretary of the Royal Medical and Chirurgical Society; Dr. Thomas Skinner, Liverpool; An Associate; Dr. Lush, Weymouth; Dr. Will, Aberdeen; The Secretary of the Royal College of Physicians; Mr. Lancelles, Manchester; Mr. R. W. O. Withers, Shrewsbury; Dr. Royston, Oxford; Dr. Shapter, Exeter; Mr. Benson Baker, London; Dr. Maunsell, Dublin; M.D.; Mr. Foster White, St. Bartholomew's Hospital; Dr. Steele, Guy's Hospital; Mr. Whitfield, St. Thomas's Hospital; A Member; Dr. Phillips, Newcastle-upon-Tyne; Dr. A. Fleming, Birmingham; Dr. J. W. Burman, Wakefield; Dr. Crossby, Nice; Dr. Nankivell, Torquay; Mr. S. H. Carter, Bristol; Dr. Felce, London; Mr. Brown, Coventry; The Secretary of the Clinical Society; Mr. H. E. Armstrong, Newcastle-upon-Tyne; Dr. B. W. Foster, Birmingham; Mr. M. C. Soutter, London; etc.

## NOTES

ON

THE INSTITUTIONS FOR THE RELIEF OF THE  
SICK, WOUNDED, AND DISABLED, OF  
THE ROYAL NAVY.\*By WILLIAM R. E. SMART, M.D., C.B.,  
Inspector-General, R.N.

DURING our visit to Plymouth, we may take a double interest, as Englishmen and as medical men, in the grand objects of architectural and engineering skill for the construction, conservation, and protection of the naval arm of our national defences.

Amid so great an assemblage of notable works, we shall find, as medical men, that there are many devoted to our own calling worthy of inspection. The parent institution of this kind is the Naval Hospital at Plymouth, which reflects the highest credit on the Admiralty. It is but a small indication of that widely spread care for the wants of the sick and wounded of the navy, that has done very much to remove the bad sanitary conditions that prevailed to the end of the last century.

It is the object of this paper, Mr. President and gentlemen, to bring to your notice the more prominent facts in the growth of the naval medical system, and to show the successive steps by which its present condition has been reached.

Our dockyards being for the care of the materials of our navy, and our hospitals for the care of the men, it became necessary that these should be twin-institutions; but it was not until 1744 that an Order in Council provided for the construction of the hospitals at Haslar and Stonehouse, near the great dockyards, on the ground of economy in money and men. Sir Gilbert Blane writes thus: "The sick and wounded of the navy were first received into Haslar Hospital in the year 1754, and it was completed about two years afterwards. Plymouth Hospital began first to be occupied in 1760, but was not completed till 1764." Previously to these dates, the sick and wounded were landed at the seaports, boarded in lodging-houses, and treated by civilians. The naval medical charges were thrown as much as possible on the Chest of Chatham. The surgeons who attended the wounded, and the people who lodged and boarded them while under treatment, were, before the Commonwealth, paid out of the chest. Until the year 1763, there was no other source of out-pensions. Until 1796, the surgeons afloat were paid, out of its funds, twopence per man per month, to provide medicines and instruments; and until 1812, the chaplains received from it fourpence a man per month ("by the ancient custom of the service"), as the main part of their emoluments; the funds being derived from stoppages out of the pay of the seamen and officers.

The Chest was an early benefit society, or brotherhood, like other trade guilds and corporations. It was the parent of our naval medical department, pension office, spiritual aid, and system of education for navigating officers. It was, indeed, a venerable institution, founded on the principle of self-help, by those gallant and charitable spirits, who stayed to play out their game of bowls in the little amphitheatre under the Hoe, before they embarked, with light hearts, to combat the great Armada, whose sails then whitened the horizon.

In the year 1654-5, a period of war, the income of the Chest was £4512:10:11½, and its expenditure was £4531:18:10½, out of which were paid pensions to wounded men, relief to widows, the charges for the wounded of the navy, aid to the inmates of Sir John Hawkins's alms-houses at Rochester, a gift to a teacher of navigation to all comers at Chatham, and the salaries of the surgeons at Chatham, Woolwich, and Deptford.

In the year 1802, the income had reached £80,000, and the deposits in the Consols amounted to £281,500, undergoing yearly increase, while the demand on the Chest for pensions was decreasing. There were only 8094 pensioners, of whom it was said many were not necessitous, receiving aid according to this scale:

For the loss of both eyes .....	£12	0	0	a year.
" one eye .....	4	0	0	"
" one eye (if sunk) .....	6	0	0	"
" a leg, above the knee .....	8	0	0	"
" a leg, below the knee .....	6	13	4	"
" an arm, above the elbow .....	8	0	0	"
" an arm, below the elbow .....	6	13	4	"

For compound fractures, and contusions of leg and foot, arm or hand, so as very much to impair their use .....

For ulcerated legs .....	4	0	0	"
For a fractured skull .....	4	0	0	"
For a double rupture .....	6	0	0	"
For a single rupture .....	4	0	0	"

This scale of pensions seems to have undergone very slight improvement indeed through a century and a half; the pensions were very much the same in 1654 as in 1802, and all pensions from the Chest at Chatham ceased on the recipients becoming inmates or out-pensioners of Greenwich Hospital.

In the year 1814, the Chest Fund of £1,355,400, together with its estates, was amalgamated with the funds of Greenwich Hospital.

It had been useful in its day; but it seems to have retarded, of late, rather than to have advanced, the interests of the sick and wounded, hurt and maimed, by its vicarious performance, on a smaller scale than was just, of those duties which the State was slow to accept so long as they were adopted by this offspring from the service itself. So long as it existed, all these important matters were regulated by standards of ancient date, and practices that were introduced to meet the wants of the service in the days of the Stuarts remained unaltered at the beginning of this century; although the very reason for its existence had ceased in 1763, when the State undertook to grant out-pensions of Greenwich Hospital.

This good work of the men who fought the Spanish Armada stood alone as the helper of the maimed and disabled seamen of the navy over a century, until the battle of La Hogue filled the streets of London with maimed men, and aroused the compassion of Queen Mary. At her dying request, the palace of Greenwich was devoted to their use as an hospital; and funds for its maintenance were raised by patriotic gifts and bequests, by a tax on the wages of all seamen, by confiscations, by percentages on prize-money and freight-money, and by unclaimed prize-money.

In 1704, it was opened to receive 100 inmates; and in 1814, after the great naval wars, it accommodated 2710 men, but about the year 1850 a decline commenced in its numbers. In 1865, it was in part cleared of its inmates; and in 1869 it was closed as a naval hospital. During a hundred and sixty-five years, it was styled the haven for maimed and worn-out sailors; and I believe that it most fully merited that reputation. The reasons for the decline in number of its inmates was the decrease of pensioners, and the improved rates and conditions of the out-pension list; but, notwithstanding these causes, there will ever be a residue of worn-out friendless men, to whom such a retreat would be an inestimable boon.

The State has taken possession of Greenwich Hospital, and its income of nearly £150,000 a-year, with which it supports the Greenwich schools, improves the pensions for twenty-one years' service, after the men have reached fifty-five years of age; and in this way the fund of £2,814,000 belonging to the seamen has become a subsidy to the State.

As medical officer of the hospital, I examined into the nature of the diseases of its inmates; and I carried this back to the year 1850, being the period of its decline, representing only a minor proportion of the good it had done. I found that, in its last twenty years, Greenwich Hospital provided a last home for 4224 inmates, whose mean of age at the time of death amounted to 70 years:

With a percentage of deaths above 60 years.....	85.5
" " 70 " .....	64.5
" " 80 " .....	23.0
" " 90 " .....	1.32

These facts exhibit well that it was the special home for the aged sailor; and I think it may be inferred from them that life was prolonged by the care and comforts provided in the hospital. The man without home and family found a home there, and this was done at no cost to the State. Since the abolition of this friendless seaman's home, a commission has sat on Chelsea Hospital, the analogous institution for the army, but which is maintained by an annual Parliamentary grant, and not on its independent funds and properties. That commission has given reasons why Chelsea should be maintained at the public cost, in order to provide a home for about 600 aged soldiers; and the question arises, ought not Greenwich to have been spared for similar reasons? *à fortiori*, that for its maintenance no annual vote was required.

As a substitute for this last home of the aged sailor, permission has been granted for the admission of sick pensioners into the naval hospitals at the out-ports; but for this boon the pensioner must surrender his entire pensions, whether for long service, or wounds, or both, and if he have a wife and family dependent on him, they will share among them the sum of two shillings a week, paid while he is in hospital. It is only in extremity that the pensioner is driven into a naval hospital,

\* Read before the Public Medicine Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

where shelter is offered him in lieu of his ancient right to it at Greenwich Hospital. Some greater consideration might surely be extended to himself, and those dependent on him, when illness casts him down, as the contrast of his forlorn case is very great with that of a half-pay or retired officer, who, being ill, can gain admission to a naval hospital, at the relatively small charge of from tenpence to three shillings a day, according to his rank and the length of his stay in hospital. To the officer's family it is pecuniarily a benefit, but to the pensioner's it is a sacrifice, for the bread-winner to go where he has the best chance of restoration to health. Virtually, the late changes have brought back the condition of the worn-out and disabled seaman to what it was under the old Chatham Chest—i.e., under a system of out-door relief, without adequate residential advantages as an alternative.

From this review of the history of institutions that are now things of the past, we may take a survey of our existing naval hospitals, of which so fine an example is now near at hand for our inspection.

It is learnt from Evelyn's correspondence, that, in 1666, the propriety of building an infirmary at Chatham was pressed by him, under the patronage of the king himself, the country being at war with the Dutch; but, from causes unknown, the question became dormant until 1741. In the meantime, there had been several wars, during which the practice of the Chatham Chest was continued, of landing the sick and wounded at the naval ports, and placing them under civilian charge. The evils of that system were great and manifest, and they were set forth in a memorial from the Admiralty to his Majesty in Council, dated 15th September, 1744, which makes reference to a previous memorial of 26th October, 1741, the country being then at war with France and Spain. It states: "The want of royal hospitals is the cause that the lodging, diet, and nursing of sick men is performed by contract, a method liable to such abuses as are often fatal to the health of the seamen, notwithstanding all the care taken to prevent it. But, when the folly of the poor men is considered, intoxicating themselves with strong liquors in the height of their distempers, the great numbers that are swept away by such intemperance, and the desertion of great numbers who recover, both compassion to them, and the interest of your Majesty's service, require the putting a speedy stop to an evil of such pernicious consequence, which can no ways be effectually done but by building hospitals," as had been urged before by Mr. Evelyn. This representation led to the building of the hospitals at Haslar and Plymouth: the former receiving patients in 1754, and the latter in 1760, before their completion.

In point of time, there is so little difference, that it is strange to find two plans so distinct carried out almost together. It proves that the Admiralty were open to new ideas; and, in fact, in matters of hospital construction and management, the Board has always shewn readiness to adopt the most modern ideas and improvements. Thus, it happens that our naval hospitals present early examples of three plans of construction; viz., palatial, block, and pavilion.

The palatial system is of square or elongated quadrangles, with open interior courts. The prototype of this is King Charles the Second's palace at Greenwich, forming the north-western building of the hospital, repeated in Queen Anne's quarter, both facing the river. This was the design of Inigo Jones, which Wren improved on greatly in the two larger buildings at their rear, named after King William and Queen Mary. Haslar was built after the plan of the parts intended by Inigo Jones for a palace, and not after that of those planned by Wren as a hospital. Haslar forms continuously three sides of a square, open behind; the receding parallel sides are alike, being elongated quadrangles, with closed courts, ill adapted for complete ventilation; and the main wards are situated in these wings. The front, which connects the wings, contains a central colonnaded vestibule, having offices on each hand, and behind them open courts of smaller dimensions than those in the sides; above the ground floor it is made up of wards. It was designed for 1800 patients, with 600 cubic feet for each; but, on modern principles, it ought never to receive more than half that number.

The block system of cubic self-contained buildings, connected by an external colonnade, is well represented at Stonehouse by a central square, surrounded by ten large blocks containing wards on three floors, with four interspersed ground-floor buildings for stores, offices, kitchen, bath-rooms, etc., and one grand block, containing chapel, dispensary, museum, junior officers' quarters, etc. Each block contains six wards, on three flats, the flights of stairs occupying an angle of the block ending on landings into which the doorways of the wards open, and on which the water-closets are placed. Each ward has its open fireplace for warmth and ventilation, and also a small stove for the nurses' use in preparing the medical comforts for the patients.

The military hospital, on the opposite side of the creek, is also of detached blocks in a single row, connected by a colonnade in front of the blocks; and the Naval Hospital, Chatham, is on a similar plan.

Sir Gilbert Blane, in his *Observations on the Diseases of Seamen*, 1799, page 176, relates that "M. Tenon, a French physician, who, by his King's order, had made a comparative review of most of the hospitals in Europe, with a view to the reformation of those in Paris, and visited this one in 1787, gives the preference to it over all others, in regard to the judicious construction and distribution of the buildings." This is a high testimony to its merits, which appears to have been deserved.

In the pavilion system, the wards are arranged in distinct blocks also, but communications are kept up between them on the several floors by corridors that form a connecting screen from base to roof, and thus thorough ventilation around the blocks is prevented. It is applicable only to hospitals in single rows or terraces; but when these are placed near each other, all the demerits of the palatial quadrangular system, as far as concerns ventilation, are reproduced.

Woolwich Marine Infirmary is constructed on this plan, with two main wings retreating, to form the angles and ends, and four smaller intermediate blocks, connected by screens containing the corridors. The military hospitals at Woolwich Common and at Netley are merely repetitions of the parts of that infirmary which is now occupied as military officers' quarters. They have an advantage in the wards having windows on both sides and at one end; the windows reach to the ceiling, and have a swing-sash at the top for ventilation; and each ward is, in fact, a distinct hospital, opening into a corridor running the entire length, and communicating with all the wards on the floor.

The last new hospital, St. Thomas's, London, combines all the advantages of both the block and the pavilion systems, and appears to leave no room for further improvement in nosocomial construction.

There is no recent statistical information concerning the naval hospitals; but, in the volume referred to, Sir G. Blane, who was a commissioner for the sick and wounded, with official records at hand, has given the gross statistics of Haslar and Stonehouse, from 1755 to 1797, including forty-four years, which he apportions nineteen years to war, and twenty-five to peace time, and compares the results, which may be presented thus:

Hospitals.	Entire of 44 years.		War periods, 19 years.		Peace periods, 24 years.	
	Admissions.	Deaths.	Admissions.	Deaths.	Admissions.	Deaths.
Haslar .....	177,390	9429	121,936	7268	56,454	2161
Stonehouse ....	111,634	5424	74,780	3661	36,854	1763
Totals .....	289,024	14,853	196,724	10,929	93,300	3924

These numbers yield ratios of mortality per thousand admissions, as follows:

*Ratios of Deaths to 1000 Admissions.*

Hospitals.	Entire period.	War.	Peace.	Difference.
Haslar .....	53.15	59.60	38.28	21.33
Stonehouse ..	48.59	48.95	47.84	1.11

A very remarkable feature of this is the great difference of results between the war and peace periods. It is at Haslar 21.32, and at Stonehouse 1.11 per thousand; the former presenting an extreme variation, and the latter scarcely any variation from the mean of the entire period. We may conclude that there must have been some very special, if not eccentric causes at work to produce results so different as these. The difference at Haslar is as incredible in its excess as that of Stonehouse is in its deficiency; and, being unable to explain either, I imagine there must be somewhere an error in the numbers—for, if these be true, Haslar was as superior to Stonehouse in time of peace as Stonehouse was to it in war. It is to be regretted that we have no hospital statistics of this century to guide opinion on such essential points.

Although these ratios are inordinate to modern eyes, yet they stand very favourably in relation to their own time. Blane quotes from *Mémoires sur les Hôpitaux de Paris*, 1788, numbers and proportions that give the following ratios of deaths per thousand to admissions at the great European hospitals.

Edinburgh, Royal Infirmary.....	40	per 1000
Vienna, General Hospital.....	75.8 to 80	"
Rome, Santo Spirito .....	98	"
Rouen, Hôtel-Dieu .....	100	"
Paris, Hôtel-Dieu .....	222	"

To which, as physician to it, he adds:

London, St. Thomas's .....	74	"
----------------------------	----	---

The lowest of these civil hospital returns, except that from Edinburgh, is 15 per thousand above the war ratio of Haslar, and 25 per thousand above that of Stonehouse.

In a Parliamentary paper, dated July 20, 1869, being the Report of

a Civil Commission appointed to inquire into the condition and organisation of the naval hospitals, we have the latest authorised official statement concerning them. From it we may quote as follows, in proof of the manner in which these establishments are conducted by naval medical officers.

"Speaking in general terms, we would say that the management of the large naval hospitals is in all respects admirably adapted to secure the comfort and well-being of the patients. They (the establishments) represent the perfection of intelligent hospital construction and administration, but are unattainable in our London hospitals. It would be, in our opinion, much to be regretted that any change should be made which would tend to cripple these noble institutions: nor would it be becoming for us, as officers of the metropolitan charities, to write any report upon the naval hospitals, without recording distinctly our opinion that their medical arrangements are, in all respects, admirable, and such as voluntary foundations would willingly copy, if their circumstances permitted."

This unbiassed judgment as to the present condition of the naval hospitals testifies as strongly to the wisdom displayed in their original construction, as it does to the continued watchfulness to avail of every new resource of medical science, by which these institutions are rendered worthy of such high encomiums. But, however complete our hospitals may be in themselves, these advantages may be always neutralised by overcrowding of the patients. Sir Gilbert Blane was pleased with the great diminution of mortality in his day, when 800 cubic feet of space was the maximum allowed to each patient. Advanced hygienic knowledge now allots 1000 cubic feet as the minimum in our military hospitals, and some civil hospitals increase this even to 1600 feet. In future wars the capabilities of hospitals will be rated by a modern standard; and it will be found that our existing naval hospital accommodation will not exceed that for 2000 men. At the beginning of this century, our naval force averaged 120,000, and for it the naval hospitals at Haslar, Stonehouse, Chatham, Yarmouth, Deal, and Paignton, were unequal to the duties. Sick and wounded seamen and marines were then received for treatment at the London hospitals and at Greenwich Hospital; and an Admiralty official, styled "Superintendent of Town Hospitals", was charged to visit these hospitals at least thrice a-week, to look to the supplies of clothing and necessaries, to visit out-patients for the same purpose, and to see that cured men were sent back to their ships.

With these facts before us, it may be doubted that, in the event of a European war, our hospital accommodation would suffice. Such a war will employ a large channel fleet or fleets. Yarmouth, the Doggerbank, the Nore, and the Downs, will be once more the roadsteads in use. Our naval hospital accommodation for these is reduced to Melville Hospital at Chatham for 300 men; and, should such a war occur, Greenwich Hospital, which is easily accessible by steamers, might be utilised consistently with its original purpose as the great hospital for the East Coast fleet: otherwise, the London hospitals might be again occupied, as in the days of Charles II, by the sick and wounded of the fleet.

The health of the navy has undergone steady improvement during this century; in fact, the commencement of it may be dated from several years earlier than that; for, when Blane wrote in 1799, he alludes to a recent reduction of the medical staff at the hospitals as the result of that improvement. He states, on the authority of Dr. Lind, "that, when the grand fleet arrived at Portsmouth in 1779, a tenth part of all the men were sent to hospital, and that the diseases were mostly fevers." On his own authority, he made comparison of the war periods with France, 1778-82 and 1793-98, each inclusive of five years, and he described how that at Haslar and Stonehouse there had been admitted 27,000 more patients during the former than during the latter period. He considered the causes to have been, chiefly, less improvement and its evil of infection of epidemics of fever, improvement in the discipline of ships, the liberal use of lemon-juice, increased encouragement to surgeons, and the enforcement of medical regulations.

Since that era, the prevention of diseases among seamen has not been neglected; medical influence has continued its exertions with immense advantage to the sea service. Peculiar hurts, wounds, and accidents, from which landmen are exempt, must remain for ever the special casualties of seamen; but even these may be deprived of much of their fatality. Scurvy and typhus have been banished from navy returns; but there still remain with undue prominence the reports of yellow fever, syphilis, rheumatism, and phthisis, which are, however, being reduced, under hygienic measures, more nearly to general ratios; and when that has been effected, the seaman's life, always hazardous, will be acceptable on account of its superior healthiness.

A Parliamentary abstract of the health of the navy, 1869-70, affords, in a statistical summary of the last fourteen years, as valuable a standard

for future comparisons as Sir Gilbert Blane's *Observations* have done. If this good work were so extended as to include the fourteen years' ratios of all the diseases in the nosological returns, classified for the several stations, the navy would possess beacons and guarantees for the guidance of its medical officers, wherever placed, superior to those of most public services.

The abstract exhibits the mean ratios to 1000 of force, for the whole navy, as follows.

Admissions to sick list.....	1409 per 1000 men.
Invalided from service.....	34.2 "
Died in service, total .....	14.0 "
" from disease ...	10.4 "
" by casualties ...	3.6 "

To this mortality of fourteen per thousand, I think there should be added at least an eighth of the invalids, as men suffering from diseases sure to terminate fatally within a near period, whose names do not appear in any later navy return; and, on the other hand, to arrive near the amount of death by disease, it is necessary to abate those by violence, amounting to one-fourth of total mortality, which will make the approximate death-rate by disease fifteen in the thousand of force among males between 15 and 45 years of age.

The Report of the Registrar-General for England for 1864, will admit of comparison with its standard of mortality at home, framed on the annual reports from 1850 to 1861. It subdivides the ages from 15 to 45, and affords the following interesting results per thousand of population.

Annual Male Mortality of England to 1000 living.

Ages.	Mean of death-rate.	Localities.		Mean by violence.	Principal Causes.
		Min.	Max.		
15 to 20 .....	6.69	4	11	0.86	Exanthems, phthisis.
20 to 25 .....	8.83	5	12	0.96	Phthisis, typhine.
25 to 35 .....	9.57	5	20	1.00	Phthisis, fevers.
35 to 45 .....	12.48	11	18	1.15	Phthisis, monorganic diseases.

As the nosological returns of the navy are graduated to ten yearly periods of age, a similar table to this would show an interesting comparison of the chances of death to Englishmen as civilians at home, and as naval seamen, it being borne in mind that the latter are selected men. In this table, the deaths by violence have to be deducted from the mean ratios; the minima are the means of healthy country districts, and the maxima are those of unhealthy towns. In London the mean male mortality between 35 and 45 is 16.29 per thousand, and 3.03 of that mortality, little less than a fifth of the whole, takes place in the great hospitals. This is, perhaps, not far from the average mortality of the whole navy of Britain. The great difference of localities at home is similar to that of the foreign stations, of which some are healthy and others unhealthy, and the causes of mortality vary greatly among them. At home, mortality is always related to the density of the population, which may also apply to classes of ships, but it cannot do so to stations.

From the latest Report on the Health of the Navy, we learn that the most sickly stations of our fleet are China, West Indies, and Brazil.

Mean Ratios to 1000 Force, for the Year ending June 30, 1870.

	Cases.	Invaliding.	Death.
General average .....	1,224	32.2	10.3
China .....	1,646	60.4	24.2
North American and West Indies ..	1,559	34.2	23.1
Brazil .....	1,975	32.8	18.7

The causes may be assumed from the high ratios of remittent fever, dysentery, and phthisis, on the China station; of yellow fever, phthisis, and heart-disease, in the West Indies and on the Brazil station.

The class of vessels which suffer most are the small gun-vessels, which, it may be presumed, are the worst ventilated, and lie longest in rivers and tidal waters, and are the least disciplined; and, still more than these, the receiving ships stationary at Port Royal, Jamaica, and in the harbour of Janeiro—the former of which is a convalescent and the latter a hospital hulk, both receiving invalids and others waiting passage. It is satisfactory to learn, that the substitution of iron for wood in our fleet has been productive of improvement in health: as the above report shows, for the ironclads, ratios of 1266.6 sickness, 32.1 invalidings, 8.2 deaths, against 1224 sickness, 32.2 invalidings, 10.3 deaths, the general averages of the service in the year 1869-70.

In the nosological returns from iron-clad ships, there is a slight increase of admissions, which may indicate increased care of slight cases, with perhaps an increase of injuries, where such unusually heavy weights are dealt with, yet there is a minute decrease of invalidings

for the serious maladies, and a remarkable decrease of the death-rate. As the mean ratios of sickness in them on the less healthy stations are the general averages of the stations, and as the mean ratios of death on those in China and the West Indies are also under the general averages, it may be confidently expected that, when all the sanitary conditions of these vessels are known and attended to, the change from wood to iron in the construction of ships will be found of signal benefit to the health of the navy. Superior means of cleansing and ventilating decks, holds, and the bilges, and the interspaces of the ribs and those under the engine-rooms, are already advanced improvements, from which high results may be reckoned on in ironclads; and as those means are perfected, so we may calculate on a reduced rate of sickness and a diminished mortality from yellow and remittent fevers, dysentery, and bronchopneumonia, to which may be assigned three-fourths of the present large amount of phthisis.

I have dwelt on professional matters that will be more acceptable at a naval port, where we breathe the sea-air and look at ships, than they would be elsewhere. I have endeavoured to show:

1. How the charitable views and exertions of those who defended the country at sea in the days of Queen Elizabeth have influenced the medical affairs of the navy; and how the principles established, and the system adopted by them, have been revived, after apparent disuse, as a national instead of a class means of dealing with the residuum of the crews of our fleets: the accumulated funds, by defalcations of pay, etc., by voluntary offerings, endowments, bequests, and Parliamentary grants, being now availed of by the State, to supplement its own pensions, in providing for its maimed, disabled, and worn-out seamen and marines, when aged.

2. That the absolute necessities of the country in war led to the construction of the naval hospitals; and that, although their institution was postponed eighty years after their necessity was recognised, yet, like the fable of Minerva springing armed from the brain of Jove, they were designed on principles that have stood the test of time, and are still considered perfect models of their kind, fulfilling to the utmost their intent and functions.

3. That from the era in the internal economy of the navy, when, as Blane remarked, "impressment began to be less rigidly enforced, and to be deprived of some of its horrors, lemon-juice to be liberally allowed to ships at sea, surgeons to receive encouragement, and medical regulations to be enforced," a very constant progress of improvement in the health of the navy has gone on, until its medical statistics, gathered from every portion of the coasts of the world, exhibit mortality rates not far behind those of the general population of the British Isles.

My task is ended; and, in thanking you, Mr. President and gentlemen, for the attention with which you have listened to these notes on a branch of public medicine, I trust that this visit to Plymouth will, if possible, increase your professional interest in what concerns the health and vigour of that glorious service the British navy.

## THE CIRCULATION IN THE ACARDIAC FŒTUS.

By JOHN W. OGLE, M.D., F.R.C.P.,

Physician to St. George's Hospital.

THE question as to what rôle the capillaries or small blood-vessels play in furthering the circulation of the blood, has been often raised, and has lately been brought before the profession in a correspondence between Dr. G. Johnson and his "Reviewer" in the *British and Foreign Medical-Chirurgical Review*.<sup>\*</sup> The subject must be allowed, for every reason, to be an interesting one; and I cannot but regard it as being somewhat strange that its discussion, after having advanced to a certain point, should apparently have been allowed to foreclose without any allusion on either side to certain observations which have been made by several writers in past years, and which would seem to constitute a necessary link in any chain of discussion on so important a subject. I desire in this communication to refer the reader to one or two facts which must be recognised in anything like a complete survey of data forming a basis for such discussion.

In support of the proposition that the arteries alone suffice by their contraction to carry on the circulation, the reviewer of Dr. Johnson had quoted the case of an acardiac fœtus which Sir B. Brodie in 1809 described in the *Philosophical Transactions*, and which had been alluded to erroneously by Mr. Palmer, in his notes on the works of Hunter, as having lived some time after birth. It proved, however,

that Brodie had described the fœtus as having been born dead; and this important statement, which Mr. Palmer had overlooked, had not been referred to by the reviewer. Consequently the supposed instance of viability of such a monster turned out to be not a fact.

Still the fœtus without a heart had lived *until* birth, and had originally been supposed by Brodie to have furnished an example of the circulation having been carried on apart from the influence of a heart—i. e., of any *vis à tergo*. This supposition, however, was subsequently set aside by the statement of Dr. Young, that, whenever an acardiac fœtus exists, there is always a second fœtus, well developed and possessing a heart, as an attendant; and this dictum was strengthened by Sir Astley Cooper, who not only described in the *Guy's Hospital Reports*, vol. i, 1836, a case of an acardiac fœtus which was a twin, the other fœtus having a heart; but went further, and showed the means or channel of communication between the two fœtuses, proving by injection and dissection that the heart of the perfect fœtus drives the blood through the vessels of the acardiac one by means of direct anastomosis between the arteries and veins of the two fœtuses at the junction of the umbilical cord with the placenta. Appended to this communication by Sir Astley Cooper was a declaration by Brodie acquiescing in Young's statement, accepting Cooper's explanation, and correcting the mistake which he had himself previously made in supposing the circulation in the acardiac fœtus to be independent of the heart.

The above facts are those (if I read it aright) concerning this question of the independence of the circulation, which have been elicited by the discussion between Dr. Johnson and his reviewer. Taking an interest in the subject, and being led by the discussion to follow it out to some extent, I found that other facts also exist connected with it, which should not be lost sight of, and which, as I before said, have been brought forward by those engaged in the subject in past years. Of these, I propose to give a short summary, by way of adding something towards the interest and completion of the discussion.

In the first place, I would allude to a paper on Acephalous Fœtuses\* in the first volume of the *Guy's Hospital Reports*, 1836, p. 218, by Dr. Hodgkin. This was, in fact, a letter to Sir A. Cooper, and contains the history and description of several monstrous productions, and also an abstract of what had hitherto been written on the subject by English and foreign writers, including Brodie's case before alluded to. In this paper, Hodgkin specially dwells on "the mode of circulation through the bodies". He refers to the fact, previously alluded to by Breschet, that in almost all cases of acephalous fœtuses the heart has been wanting; and he observes that, in a large majority of cases, the acephalous fœtus has been accompanied by one or more perfect children—stating that the "inquiry immediately presents itself, how far the circulation in the monster was connected with that of the perfect child, and depended upon it;" and to this idea, started by Young, he had alluded in his Thesis in 1823.† He refers to the fact that Dr. John Clarke (and quotes the case) was the only author who had previously demonstrated the vascular connexion of the two placentæ. (See *Phil. Trans.*, 1793, p. 154, "A Description of an Extraordinary Production of Human Generation.")‡ He then notices the views held by various authors as to the maintenance of the circulation in the fœtus in the absence of a heart, observing that Mery and Lecat referred it to the direct impulse of the mother's heart; that Ponjol and Winslow concluded there was no circulation—the first thinking he found no other vessels than veins both in the fœtus and umbilical cord, whilst the latter found only arteries. Monro and Tiedemann both consider that the circulation is maintained by the impulse given to the blood by the vessels themselves, although they do not agree as to the course taken by the blood, Tiedemann considering that the blood is conveyed from placenta to fœtus by the umbilical arteries; and in this view Breschet coincides, endeavouring to support it by analogy with the circulation in fishes and mollusca.

Dr. Hodgkin then gives in detail, which it would be too long to recapitulate, the views held by those who have described this kind of malformation, as to the distribution of vessels and the course of the fluids in the fœtal mass. Appended to the above paper by Hodgkin is an account of the structures of the placenta and imperfect fœtus by Sir A. Cooper,§ which was referred to in the recent controversy in this JOURNAL, and to which I have alluded already. In this account, as before said, Cooper demonstrates the mode of support and circulation of the

\* He points out that the term "acephalous" comprehends not only those instances where the head is wanting, but also those in which this and every still more considerable degree of deficiency may be met with.

† This Thesis I have had no opportunity of seeing.

‡ The mother was a patient in the General Lying-in Hospital in Store Street, London.

§ The placenta and fœtuses had been sent by Hodgkin to Cooper for examination.

\* See Dr. Johnson's article on the Physiology and Pathology of the Circulation in the numbers of the JOURNAL: for May 1870; and correspondence in the numbers for June 1871 and 1872.

second or imperfect foetus, which receives through its own umbilical artery from that of the perfect foetus the current which, after entering the aorta and circulating through arteries and veins, returns by the umbilical vein of the imperfect into that of the perfect foetus. Following the description by Sir A. Cooper is the letter of Sir B. Brodie before referred to, in which he expressed satisfaction with the arguments of Dr. Young. In the same year (1836) was published, in the tenth volume (p. 204) of the *Dublin Journal of Medical Science*, an account which Dr. Houston had given to the Medical Section of the British Association at Bristol of a human foetus without brain, heart, or lungs; with observations on the nature and cause of the circulation in such monsters. In this he refers to a paper which he had previously read before the Surgical Society of Ireland in connexion with the case, and minutely describes the dissection of the specimens; and, after adducing and examining the views of other physiologists on the circulating organs in the monster, such as Tiedemann, Brodie, Breschet, Monro (alluding to the case of Dr. Clarke), he characterises as untenable the view of Astley Cooper that the blood is driven by the heart of the perfect foetus from the vessels of the perfect into those of the imperfect foetus, and back again; and seeks to establish, by arguments drawn from dissection, that the blood passes into the imperfect foetus in a normal way—*i. e.*, by the umbilical vein, and back by the umbilical artery; but that in the foetus itself the arteries and veins change functions, so to say, the circulation being inverted—the blood entering by the veins, and returning by the arteries. He repudiates any supposed influence of the heart of the perfect foetus on the circulation in the imperfect one, and attributes to the placenta an inherent power of drawing in and ejecting again the blood which traverses its vessels; and suggests that, by means of this and like properties in the foetus itself, the circulation may be carried on between them without any other influence whatever. Subsequently Dr. Marshall Hall wrote a paper in the *Edinburgh Monthly Journal*, 1843, in which, adopting Dr. Young's idea, he rebutted at length the conclusions both of Sir A. Cooper and of Dr. Houston. He objected to Cooper's view that the blood is carried from the perfect into the imperfect foetus through the umbilical artery by means of an anastomosis between the arteries of the two beings, as constituting an inversion of the order and course of the circulation in the cord; and to Houston's view, as being an inversion of the circulation in the foetus, and because it leaves us without a power to which the circulation of the blood in the imperfect foetus can be referred. As a proof that the action of the heart of one foetus does extend to the umbilical cord of a second foetus, Dr. M. Hall quotes a highly interesting case from Lallemand of the birth of twin foetuses. After division of the umbilical cord of the first-born and ligature of the foetal extremity, it was found that from the end connected with the placenta an unusual amount of blood was pumped out in jerks or pulsations—"lancé par saccade". This led to the suspicion that another foetus was in the uterus—as proved, indeed, to be the case.

Dr. Hall asserts that there is no proof whatever of the capillaries possessing any intrinsic power of moving or circulating the blood, but that the influence of the heart may and does extend to and through the capillary vessels; moreover, that the heart's influence in the case of a second perfect foetus extends not only along the cord and through the placental circulation, but through a second series of capillaries in the body of the imperfect foetus, illustrating this extended heart's influence by what occurs in the case of fishes—the blood being distributed first through the capillaries of the lungs, then through capillaries of various organs of the body, and lastly again through those of the portal circulation; also by experiments, which he relates, on the fin of the eel. He observes: "My view of the subject is this. I suppose the heart of the perfect foetus to propel the blood to the imperfect foetus, as Dr. Young suggested; but not immediately from its umbilical artery into that of the other, according to the view of Sir Astley Cooper, but through the capillaries of the placenta into the umbilical vein, and through the umbilical vein and a series of capillaries to the aorta; and not, according to the views of Dr. Houston, in an inverted direction. There may appear to be some difficulty in conceiving how an anastomosis between the umbilical artery of the perfect foetus with that of the imperfect can exist without arresting or impeding the flow of blood towards the placenta in the latter. The fact is to be explained, I believe, on the principle of lateral action. As a stream of air or of water, passing by other air or water, carries with it the adjacent particles of the latter; and as a stream of air or water, passing rapidly along one tube immediately by the orifice of another tube containing a similar fluid, either at rest or flowing with less rapidity in the same direction, draws the fluid from the latter; so the blood propelled with energy along the umbilical artery of the perfect foetus, immediately by a branch anastomosing with that of the imperfect one, will draw by lateral action the blood contained in the latter into its own rapid cur-

rent. The blood in the artery of the imperfect foetus is thus drawn by the blood propelled in that of the perfect foetus towards and into the placenta. This effect will also be proportionate to the greater velocity of the blood propelled by the heart of the perfect foetus. Thus, then, in reality, and on two different principles, the blood is propelled to, and attracted from, the imperfect foetus, by the power and action of the heart of the perfect one, and along the customary channels."

As a rejoinder to the above, it would seem that Dr. Houston read a second communication on the same physiological question before the British Association in August 1843 (*Dublin Journal*, Jan. 1844); and this in its turn was followed by further observations by Dr. M. Hall, in which he again sums up his views as follows. "According to my view of the blood in the acardiac foetus, the blood is propelled by the heart of the perfect foetus through both placenta, along both umbilical veins, into both foetuses, with equal velocity. The difference between the two cases is observed in the umbilical arteries, and in these only; for, whilst the blood is propelled rapidly along that of the perfect foetus by means of the immediate action of the heart, it is propelled slowly along that of the acardiac foetus by the action of the same heart, diminished in its energy by having already propelled the blood through the vessels of the placenta, of the cord, and of the foetus, just enumerated. In these arteries, the blood of the perfect foetus comes into contact with that of the acardiac foetus through the medium of anastomosis. At this point, the rapid current of the former attracts the slow current of the latter, by 'lateral action,'\* precisely in proportion to the degree of the difference of their velocity."

I should say also that Dr. M. Hall alludes to the opinions of Dr. Graves (*System of Clinical Medicine*, 1843, pp. 82, 485) and Dr. Carpenter, both of whom thought the views of Dr. Young and Sir A. Cooper regarding the circulation in the acardiac foetus to be erroneous. Dr. Graves had quoted the acardiac foetal circulation as illustrative of the possibility of derangement of vital action of any part or organ, and the production of congestion and inflammation independently of the action of the heart or of the general circulation—a view opposed by Müller, but entertained by several German physiologists, who attributed to the blood an automatic movement or power of propulsion. He had also, in treating of inflammation and the motor powers which cause and regulate the circulation, etc., dwelt at length on the attracting and propulsive power of the small vessels, strengthening his position by arguments derived from the known action of minute vessels in certain lower animals and in plants, in furthering the movement of fluids; quoting also from a paper written in 1842 by Dr. Holland of Sheffield, on the Forces by which the Blood is circulated in Capillary Vessels. Dr. Carpenter, in his work on *Physiology*, had also accepted and propagated the view that in even the highest animals a capillary power exists, which is sufficiently strong to maintain the circulation by itself when the power of the central organ is diminished.

In Dr. Carpenter's recent edition (1869) of the *Principles of Physiology*, edited by Mr. Power, allusion is made at p. 300 to the paper above quoted, by Dr. Houston, and to the controversy between him and Dr. M. Hall. It is considered that in Dr. Houston's case it seemed impossible for the heart of the twin foetus to have occasioned the movement of blood in the imperfect one; and that some cause present in the latter must have been sufficient for the propulsion of blood through its vessels. It is also thought that Dr. Houston's reply to Dr. M. Hall, above alluded to, was satisfactory.

Such, then, are the additional observations which I find bearing on the discussion of a capillary circulation, so far as it is supported or not by the conditions of circulation in an acardiac foetus. I have ventured to seek a place for them in the pages of the JOURNAL, thinking they would be considered as possessing some interest at the present time.

P.S.—Since writing the above, my attention has been drawn to a communication (which I had overlooked) of Dr. Dickinson to the *Medico-Chirurgical Transactions*, containing a description of a foetus born without heart, brain, or liver. In this, it appears, he concludes to adopt the view suggested by Dr. Young and worked out by Sir A. Cooper, as regards the dependence of the circulation in the acardiac foetus on the heart of the healthy twin, and observes as follows. "The umbilical vein of the healthy child receives a large communicating vessel from the corresponding channel in the cord of the monster. This must be looked upon as a main trunk, which receives branches in two directions—from the placenta on one side, from the cord of the monstrosity on the other. The contrariety only remains until the two streams are mingled in their common channel. The blood passing from the placenta by the venous radicles would be mixed with the blood coming from the monster by its umbilical vein, and both together

\* Dr. M. Hall has a small chapter in which he adduces other instances of the influence of this principle of lateral action of the blood-circulation in the economy.

would be conveyed by the communicating vessel into the umbilical vein of the healthy child. A similar explanation would, of course, hold good as regards the arteries."

*A propos* of foetal circulation, Dr. Stokes, of Dublin, recently mentioned to me that he had tried once to find out what he could hear with the stethoscope on examining the abdomen of a pregnant cat. The cat was within a few days of her bringing forth, and the experiment was made with care and repeated several times. The cat had four, or perhaps five, kittens; but nothing was heard but the well-defined sound of a single foetal heart. In answer to my question, whether he had detected twins in the human subject by the stethoscope, Dr. Stokes observed that he had never examined a case of twins or triplets. He remarked, "It is said that twins have been detected by auscultation. I suppose it was by the different intensity of sounds in different portions of the hypogastrium."

## THE CLIMATE OF SIDMOUTH, WITH RESULTS OF METEOROLOGICAL OBSERVATIONS

FROM 1865 TO 1870.\*

By J. INGLEBY MACKENZIE, M.B. Cantab.,

Physician to the Sidmouth Dispensary; Fellow of the British and Scottish Meteorological Societies.

THE temperature of the body in health, and the deductions to be obtained from variations from the normal temperature in different diseases and in various stages of the same malady, have been an object of research to many of our profession both at home and on the Continent. It does not appear that the profession, as a rule, have made observations on the air of the room in which such temperature has been taken, or of the external atmosphere at the same period—a circumstance which undoubtedly would make a considerable difference in the temperature indicated.

The temperature, the moisture or dryness of the air in which we are existing, must have great influence on our human economy. The depression caused by a "muggy" day; the brightness which is proverbially the concomitant of sunshine, without entering more into detail—a matter of but little difficulty—are ready evidences of this fact. So also the climate in which we live—whether the air be dry or moist, the temperature equable, or extremely cold or hot—ought to be a study equally deserving our attention with the phases of disease which are in no small measure dependent on changes of temperature, etc. The Registrar-General's weekly returns, with which are now published the temperatures, afford most palpable proofs of increase and decrease of disease with the alterations in the temperature of the air.

Having called attention to these points, before I proceed to the subject of this paper—the climate of Sidmouth—I must remark that the public, and I fear sometimes the profession likewise, look rather dubiously on remarks on climate made by a member of our profession, as if it were impossible but they should be, from interested motives, put in too favourable a light. Fortunately, I am enabled to place in juxtaposition, in confirmation of my own observations on the climate of Sidmouth, some observations taken by a most careful observer, not liable to any bias, which coincide entirely with mine; and, in addition to this, I am able to state that the instruments and their positions have been examined and approved by Mr. Glaisher.

The works on climate of Sir J. Clark and Dr. Scoresby Jackson, though most admirable as wholes, cannot but fail of necessity, from the magnitude of the ground they cover, to be sometimes in error. The account of Sidmouth in the former is founded on observations taken one mile out of Sidmouth for a period of less than one year only. The account in the latter is obtained from some other publication. Here let me suggest the publication of a "Dictionary of Climate", with short descriptions written by observers conversant with the localities of which they write, which would doubtless be valuable in time as a work of reference.

Sidmouth lies in the eastern part of Devon, almost centrally in the district bounded by the Axe and Exe. It lies at the centre of the segment of a circle which forms the great bay bounded on the west by Berry Head and on the east by Portland Bill. Its latitude is 50 deg. 43 min. 40 sec. N., longitude 3 deg. 13 min. 3 sec. W. The town of Sidmouth lies in a winding land-locked valley trending downwards towards the sea, bounded on each side by lofty hills 500 feet in altitude, and closed in on the northern side by another range of hills. It is exposed, therefore, to the south only. It is stated, and apparently on

as yet uncontroverted authority, that the bay, at the head of which Sidmouth is situated, was hollowed out by the action of the Gulf Stream, dividing at the Land's End; part passing to the westward; the eastern portion working up and forming the bay. And it has been argued from this hypothesis, that this is one of the reasons for the warm winter-temperature of Sidmouth. Observations on the temperature of the sea have been but rarely taken on this coast; though, by the exertions of Mr. N. Whitley, they have been taken in some parts of Cornwall; and the Scottish Meteorological Society are actively pursuing the same object, not only on the North British coasts, but also in Sweden and Iceland. The general impression is, that the sea is susceptible of less change of temperature than the land; and, if so, we may fairly argue that land lying close to the sea is liable to enjoy a climate more equable than that further distant. And, if the temperature of the adjacent sea be elevated, as suggested in the above hypothesis, doubtless it will affect the neighbouring land. That the climate of Sidmouth was not unknown to previous generations, the fact of its having been the chosen resort of H.R.H. the late Duke of Kent, and that it was here some of Her Majesty the Queen's earliest days were spent, is sufficient evidence.

The points to be observed in the climate of Sidmouth are: *a.* The equability of its temperature; *b.* Its comparative dryness—though possessing a moist atmosphere—in relation to the other parts of the county; *c.* The rapidity with which the soil dries after rain, thereby rendering exercise available for the invalid on almost every day in the year.

*a. The Equability of its Temperature.*—The avoidance of the extreme of heat or cold is what is generally understood by equability of temperature, or, in other words, where the difference between the highest reading of the thermometer and the lowest is smallest in the day, month, or year.

The average daily range of temperature during the years 1865-1870 inclusive was only 13.4 deg.; that of the summer months being 15.1 deg.; of the winter, 11.8 deg. In the years 1856-1863 (omitting 1862), the same averages (by Mr. Heineken's observation) were severally of mean daily range, for seven years, 9.8 deg.: summer months, 11.1 deg.; winter months, 8.2 deg. Hence during the winter months the temperature does not vary above from 8.2 to 11.8 deg., or in the summer from 11.1 to 15.1 deg., during the twenty-four hours.

The extent of the variation of the thermometer in each month in the year, between the extreme highest and extreme lowest, is only 30.6 deg.

The coldest days in 1870 were the 23rd, 24th, 25th, and 31st days of December. In a list of fifty-one places given by Mr. Glaisher in his Quarterly Report, on which the temperature was specially observed, it was found to be as low as 1 deg. at Taunton (that is, thirty-one degrees below freezing-point); 9.8 deg. at Greenwich (or twenty-two degrees below that point). The thermometer at Sidmouth never indicated a lower temperature than 19.4 deg., or twelve degrees below freezing-point, being ten degrees warmer than Greenwich, and eighteen warmer than Taunton.

The extreme range in the course of the year, during the six years (1865-70) to which reference has been made, is 55.6 deg.; that is, calculating the extreme from the hottest day in summer to the coldest day in winter during the whole of that period.

In proof of the equability of the climate, I have drawn up a table giving in columns the mean temperatures respectively of Sidmouth and Greenwich in each month during these years, showing thereby that, though the annual mean temperatures do not vary by more than half a degree, the temperature in each winter month at Sidmouth is warmer than that of London by from one to four degrees nearly; and, on the other hand, the temperatures of the summer months are proportionally cooler. The same has been proved above in reference to the extreme of cold, and might be also of the extreme of heat.

*b. Its Comparative Dryness.*—Devonshire is supposed to be, or has the credit of being, one of the wettest counties in England. According to an average for the year 1869, calculated by Mr. Pengelly of Torquay from the data in Symons' *Rainfall*, and published in the *Transactions* of the Devonshire Association for the Advancement of Science, it stands only seventeenth in degree of wetness or quantity of rainfall (or sixteen counties were wetter than Devonshire in 1869). The same gentleman, in another part of his paper, states: "During four years, Prince's Town was the wettest station in the county, and Sidmouth and St. George's Cyst the driest." Again: "The mean daily rate of rainfall on wet days during the four years (referred to) was .41 inch at Sheepstor, where it was greatest, and .18 inch at Sidmouth and Broadhembury, where it was least." From the same table it may be gathered that, of forty-two rain-gauge stations in Devonshire in 1869, the quantity of rain which was registered at Sidmouth was less than at any other station, with one exception, in Devonshire, the mean an-

\* Read before the Public Medicine Section at the Annual Meeting of the British Medical Association in Plymouth, August, 1871.

nual rainfall for four years being the lowest in Devonshire, St. George's Clyst having the same average.

I append a table of my own rainfall observations for six years, giving the quantity of rainfall and the number of rainy days in each month during that period, the result of which tallies exactly with Mr. Pengelly's, giving an annual rainfall of 31.68 inches, one hundred and seventy rainy days, and a fall of .18 inch on each rainy day.

Closely following the subject of rainfall is that of the relative humidity of the climate. Dr. Parkes states (*Practical Hygiene*, 3rd edition, p. 465) that "the most agreeable amount of humidity is between 70 and 80, saturation = 100. In chronic lung-diseases, however, a very moist air tends to allay cough. The evaporation from the lungs produced by a dry atmosphere appears to irritate them. Warmth and great humidity are borne as a whole better than cold and great humidity."

The great desideratum in a climate to suit persons suffering from phthisis is a moist atmosphere of a certain character—i.e., not too moist, for that is depressing and relaxing; nor too dry, for that is irritating to the mucous membrane of the air-passages; but, as near as possible, a mean betwixt these two extremes.

It appears from observations taken that the mean relative humidity for six years is 81; the mean relative humidity of the winter months, 82; of the summer months, 78. I cannot conclude this part of the subject better than by quoting from Dr. Shapter's work on the *Climate of South Devon*, 2nd edit., p. 128.

"From its size and climate, Sidmouth affords an agreeable residence to persons who have lived long in warm latitudes; it is well adapted to those labouring under affections of the liver, and during the autumn, winter, and spring seasons, for the consumptive invalid; it is probable that during the spring months it is the best place on the coast for those liable to pulmonary complaints. It has been asserted that Sidmouth is peculiarly injurious to persons labouring under menorrhagia. The experience of the local practitioners does not bear out this opinion; on the contrary, they deem it beneficial in those cases, as well as in dysmenorrhoea. It is also serviceable in cases where undue wear and tear of mind is followed by mental depression and nervous irritability. Calculus and typhus are unknown, and it is remarkably free from epidemics." These remarks of Dr. Shapter need not be taken even *cum grano salis*, which might be the case were they written by a local physician, though, in an experience of eleven years, I can confirm them in their entirety. That the climate is relaxing I strongly deny. I am quite ignorant of epidemics existing; and as to the palliative effect of the climate in phthisical cases, I could (would time permit) produce notes of numerous instances in which, if the malady were not cured by the climate, it lay dormant in some cases as long as twelve to fourteen years. To my mind, the mistake committed by many practitioners in sending their phthisical cases to warm climates is the sending them *too late*; it is in the stage of phthisical cachexia, before the mischief has developed itself too prominently by physical signs, that these climates are of use, not in the later stages, when the patient is only sent off to pass the last few days, or perhaps weeks, of his life at a distance from his home, his friends, and connections. And here there is the advantage of an English residence over a foreign one; it is more within reach of home; the houses are built to exclude cold, not (as I know to my cost in the so-called sunny south) built so as to be cool in the summer; it is within a few hours of anxious friends; it entails no sea-voyage; it has no temptations to sight-seeing; a cozy English fireside is obtainable, and there is hardly a degree of difference in the temperature. I have received letters from Nice when the snow has been reported as lying there, whilst consumptive invalids have been sunning themselves on the beach at Sidmouth. I fear I shall be accused of approaching the realms of poetry and romance, but I am prepared with data on which to ground my statements.

c. *The Rapidity with which the Soil dries after Rain.*—The town itself is built on a diluvial deposit of gravel overlying the red sandstone. To the geologist, the different strata rising up from the sea to the layer of flints on the summit of the hills afford an interesting study; the soil is of a porous character, dries most readily, so much so that in ten minutes after the heaviest rains, the esplanade, a raised walk facing the sea, is available for pedestrians.

I trust I have in some measure proved the facts with which I started. I might have added tables on the direction of the winds, showing the greater prevalence of winds from the seaward points of the compass, giving warmer feeling to the air in winter and a cooler one in summer; or referred to the quantity of ozone in the atmosphere, especially with sea-borne winds; the quality of the water; the lowness of the rate of mortality; the absence of phthisis and asthma amongst the natives of the locality; the entire freedom from epidemics; but I refrain, having already exceeded my limits.

I can only repeat that, I trust my statements may be taken not as a local matter, but as a mite thrown into the treasury of the British Medical Association on the score of the meteorology of Sidmouth.

The Tables referred to were too voluminous for insertion.

## CLINICAL OBSERVATIONS ON THE DIAGNOSIS OF THE GENERAL PARALYSIS OF THE INSANE.\*

By JOHN HITCHMAN, M.D.,

Superintendent-Physician of the Derby County Asylum.

GENTLEMEN,—It was not from the feeling that I should be able to convey any additional knowledge on the subject of "general paralysis" (or, as it has been named by an able Dutch physician, Dr. Salmon, "general paresis") of the insane, to gentlemen whose attention in practice has been especially directed to this malady, or to those who have made themselves acquainted with the writings of Calmeil, of Rodriguez, Baillarger, Meschede, Conolly, Griesinger, and others, on this grave disease, that I yielded to the solicitation of your Secretary, and consented to make some remarks on this subject, but because, as a matter of fact, I have often found, in consultation with the busy general practitioner, that he is less familiar with this disease than with others, and that a prognosis has often been given which would have been withheld had the true nature of the disease been understood.

It occurred to me that, without entering into a minute description of all the characteristics of the malady, which would occupy too large an amount of your time—without pretending to reveal what had been hid from other observers in this special path of practice, or attempting to evolve a new theory upon an obscure disease, but by simply illustrating the more prominent and diagnostic symptoms of the affection in the persons of two or three patients, I might occupy profitably a few minutes of this meeting. As I have previously stated, the malady has not received much of the attention of the general practitioner; and the aspect of the patient in the early stages of the disease is often so hopeful—the appetite, the sleep, the general appearance of the patient are often so good, and the body so well nourished, that, within my frequent observation, the medical attendant has held out to the patient's friends the most sanguine expectations of recovery; while to the experienced eye, the sufferer has evidently been smitten with an incurable disease—i.e., incurable as far as our present knowledge extends; not more hopeless, indeed, is acute military tuberculosis, than is the general paresis, or paralysis, of the insane.

The late Dr. Conolly, in his lectures on this malady before the College of Physicians in 1849, said: "It is extraordinary that scarcely a trace, if even a trace, of a description of a paralysis so distinct and peculiar in its character should be found until we come to the writings of physicians yet living." Delacy in 1822, and Calmeil in 1826, appear to have been the first to give us a full and lucid description of this malady. It appears to have been more frequent in France than in this country. It is said to be exceedingly rare in Italy. Guislain informs us that it is seldom observed in an asylum at Aversa containing three hundred and sixty beds, although intemperance is a frequent cause of insanity in that region; and he found no example in an asylum at Genoa containing two hundred and seventy beds. It has, I believe, increased considerably in this country; increased with the increasing wealth, luxury, social ambition, and display of the present time, although not unknown in a remote age. There are some who recognise the portrait of this malady in the description by Ulysses, as given by the illustrious Shakespeare in the play of *Troilus and Cressida* (Act 2nd, Scene 3rd):—

"Things small as nothing, for request's sake only  
He makes important: possessed he is with greatness  
And speaks not to himself, but with a pride  
That quarrels at self-breach; imagin'd worth  
Holds in his blood such hot and swol'n discourse,  
That 'twixt his mental and his active parts,  
Kingdom'd Achilles in commotion rages,  
And batters down himself! What should I say?  
He is so plagu'y proud, that the death-tokens of it  
Cry—No recovery."

"Possessed he is with greatness", certainly reminds one of the disease; and the cry "No recovery" is a striking sentence. The whole condition constitutes a good seed-bed for the development of general paralysis; but the portrait is incomplete, for there is wanting the physical disorder which, in association with swollen and exaggerated ideas of personal

\* Delivered at the Annual Meeting of the Midland Branch.

grandeur and importance, is characteristic and pathognomonic of the malady. There is insensate pride blended with stubbornness and anger in Achilles; yet this is not the disease; for the patients suffering from general paralysis are, as a rule, pleased and exultant in the sense of their greatness, their grandeur, or wealth, and they speak with smiling satisfaction, rather than "rage with commotion." The description of the poet indicates the kind of man who is likely to fall a victim to the disease; but it refers not to the general muscular debility, to the slow, pausing, confused hesitation of speech, which, in association with exalted ideas, as before stated, is the diagnostic criterion of the general paralysis of the insane.

The malady occurs very seldom in early adult life. It becomes more frequent after the age of thirty years; and my experience would cause me to specify the period of from forty to forty-five years of age, as that in which the malady most frequently develops itself. It affects all classes, like death itself—

"Æquo pulsat pede  
Pauperum tabernas, regumque turres":

but, in the upper classes of society, it affects the male sex almost exclusively. In thirty years, I have never seen a lady suffering from this disease; and my friends, Drs. Conolly and Stilwell, both of whom were largely engaged in private lunacy practice, informed me, in 1848, that they had never met with one. Among the female poor, and the lower middle classes of society, such cases are occasionally brought under notice. Men of a sanguine temperament, with energetic circulation and quick sensibilities, are especially liable to this formidable affliction. The causes, or alleged causes, are numerous, as in other diseases; but to give these influences force, there is generally some special individual bias. The most energetic agencies in the production of the disease in the more opulent classes of society are, I believe, intense and prolonged mental activity, carried on under emotional excitement; sexual excesses; and especially if, under either of these circumstances, large quantities of wine and alcoholic stimulants be resorted to; among the working classes, heavy and prolonged labour, sustained by large potations of ale or spirits, rather than by nutritious food and a due quantity of sleep. Dr. Maudsley, in his very able and graphic treatise on Insanity, published in Reynolds's *System of Medicine*, alleges that the two most marked cases of general paralysis he had ever seen occurred in "teetotalers", but in whom there was reason to suppose there had been, although marital, excessive and enervating sexual indulgences. So difficult is it to fulfil the apostolic precept to "be temperate in all things"; so very easy is it to adopt the Hudibrastic philosophy, and

"To compensate for sins you are inclined to,  
By sinning those you have no mind to."

Dr. Conolly doubted the acting force of sexual excess in producing this malady, because he had so frequently met with this disease in "respectable married life." This good physician erred in overlooking the uxorious amative tendencies of some men; and his refined and sensitive nature caused him to shrink from inquiries in relation thereto. Subsequent research has shown that this fault or error is among the most frequent of the antecedents of the disease.

Men with large and active brains, strong hearts, great self-esteem, carrying on ambitious projects without available capital at all proportionate to their speculations, and, therefore, subject to frequent emotional excitement as to how claims may be met or staved off, frequently fall victims to general paralysis; as do, indeed, also more pure and gentle minds discharging prolonged duties under too acute a sense of responsibility, or who have been exposed to a great and sudden shock of the feelings by the unexpected death of a much loved wife or child, or from some such causes. High designs dashed suddenly to the ground, severe fatigue sustained by alcoholic stimulants, rather than by

"Tired Nature's sweet restorer,  
Balm sleep."

are frequent excitants, as illustrated by the number of cases which occurred among the soldiers in the Grand Army of Napoleon during the disastrous retreat from Moscow.

The phenomena of the disease are difficult to describe, but easy to detect. The guiding indication is to be found in the voice, and in the muscles of the tongue, lips, and face, which minister to this function. The tongue claims our especial and primary attention, as it is the first external bodily organ to exhibit the presence of the disease. Whenever the patient is excited from any cause, the tongue fails to execute the function of speech with its accustomed clearness and accuracy: it is not, at first, a stammer, but a pause—slight and transient, but still an obvious pause, as if the person were thinking of the word as he uttered it; and this faint pause is followed by a thick-muffled tone of speech, resembling that of an inebriated person; and an attempt at speech is occasionally preceded by a quivering movement about the mouth, lips, and adjoining facial muscles—a movement analogous to that which may be ob-

served when a person is struggling under strong emotion not to weep, or is about to weep. It is not a stammering or repetition of the syllables of words, but a lingering pause, and is more especially observable when the patient speaks words possessing a considerable number of consonants. In the very incipient stage of the disease, especially in the morning, or after meals, the patient may speak many sentences without the peculiarity being distinguished, save by one familiarised with the disease through all its stages, from the first faint flickering pause and muffled accent of speech to the last stage, when the poor sufferer can utter monosyllables only, or sounds of an altogether inarticulate character. In very rare cases this special characteristic voice is unassociated with ideas of personal grandeur, wealth, and power, and is accompanied by a somewhat melancholic expression of face, although, as a rule, on being questioned, the patient will assure you that "he is quite well", or "quite happy", or "all right": this state sometimes alternates with more exultant moods. It will generally be found that such patients inherit a strong bias to mental derangement. The case of T. G. before you illustrates clearly the diagnostic speech of general paresis, the absence of exaggerated ideas, and the presence of a special hereditary predisposition to insanity. His mother was of weak intellect, and was always in anxiety owing to the vices and caprices of her husband, who drank to excess, and died of pulmonary consumption. The grandfather, the uncle, and sister, of this patient were mentally deranged, and died in lunatic asylums. He has at various times received severe injuries about the head and face. He has still a scar above the left orbit produced by a fall from a horse; and he has lost the left eye by a blow from the lash of a whip. He has drunk to excess in past years; and, indeed, for so long as he had the pecuniary means of doing it. He has been insane seven or eight weeks. He first announced himself as "well off (though a pauper), had money in the bank, and was about to build". He burnt clothes to make up a fire; threatened violence to his own and other children; and his memory is greatly impaired. The exaggerated idea of his wealth has passed away, and he is now simply imbecile. His voice is very characteristic—more marked, indeed, than is usual in the early stages of the disease—and, therefore, I thought it more instructive and demonstrative of the special sign, which, in association with certain mental characteristics, is pathognomonic of a cerebral lesion of the gravest kind. This pause in speech develops itself early, and will always display itself if the patient be angered or excited from any cause: when he shows his tongue there will commonly be found a fibrillous tremor through the entire organ, or it will be protruded with a succession of quivering jerks. It is not, you will observe, drawn to one side, as in hemiplegia, but pushed forward in an agitated way, somewhat resembling the mode in which the fang of a reptile is displayed. As the disease advances the tongue cannot be kept in a protruded state, and in the last stages of the malady is often incapable of protrusion. The malady in T. G. has made rapid and unusual progress, as might be expected in a man who has been exposed to the malignant influences which appertain to hereditary transmission; to a (probably) drunken procreative act; to gestation in the womb of a mother agitated by a thousand fears; to poor and irregular nutrition in infancy; to defective intellectual training; and the daily example of drunkenness or depravity in his father, together with all the evils which appertain to mechanical blows about the head and organ of vision; and last, although not least, to intemperance on his own part. You will remember that the stolidity, or rather dulness, of T. G. is exceptional; that he appears before you as a strong example of the physical lingual characteristics—and, I might add, of the locomotion in this disease—but also as an example of those exceptions which crop up from time to time and destroy the symmetry and mar the dogmatic beauty of systemic treatises on disease. When the slow, pausing, lingering, slightly mumbled, voice to which you have been listening in T. G. is heard in association with insane ideas of a very exalted character—such as boundless wealth, thousands of acres of land, millions of gold; or with great pretensions to business; with ardent speculations; with busy restless action; with inflated ideas of personal importance, whether as to titles, position, and the like—then, in the startling language of Griesinger, your patient "may with almost absolute certainty be considered as lost". He may, under good treatment, survive two, or even three or more years; for on June 1st last I saw a gentleman who had been thus afflicted for four years and upwards, and who was then capable of walking considerable distances; but, as a rule, the patient sinks long before this into the most abject state of corporeal helplessness: the bladder and the rectum pour out their contents unheeded, and the sufferer is wholly dependent on others for the conveyance of food to his mouth, and for every other thing which requires muscular power directed by intelligent will. But I am forestalling, and by so doing am defeating the object of my observations—namely, to enable you to recognise this malady in its early stage, and thus to escape an error in prognosis, calculated to

cause intense disappointment to friends, and unjust suspicion of defective or wrong treatment on the part of those to whose medical care the patient may be confided.

It is impossible to describe the tones of a voice in words; it is almost as difficult to define the length of a pause, or give an idea of the amount of slowness in the flow of words, which would constitute a morbid sign; but in T. G. you have had the characteristic utterance in a clear and unmistakable and highly developed form, which may, perhaps, enable you to detect the disease in its more subtle and slighter manifestations. A very distinguished observer (Dr. Meschede) has said "that general paralysis constantly exists, and is evidenced beyond any doubt by the mental symptoms, without any perceptible defect of articulation or other lesion of motility". Now, this is true only in an ideal sense. It is as if you said it is impossible to have acute miliary tuberculosis without tubercles, or epilepsy without convulsions. The mind may conceive the existence of disease in such a nascent state and recognise the distinction, but it is not demonstrative; and, practically, neither disease can be affirmed to exist until its respective phenomena are displayed. I have stated already that in early morning and after meals, and, I might have added, for long periods of time, these lesions of motility sometimes disappear; but until they are evidenced the conscientious practitioner will refrain from giving a diagnosis. I introduce to you J. S. as a patient who has displayed them, but in whom they are now faint, but still to be distinguished by a careful and prolonged examination. General paralysis, or paresis, like other diseases, has its varying degrees of intensity and its shades of expression. The perfect case—the *chef d'œuvre* of this pathology—has all these previously described lesions of lingual motility, associated with the most exalted ideas of grandeur and power; but there are others, whose career is equally rapid towards death, which possess them in a more modified form. J. S. is one of these: contentment, self-satisfaction, placidity, a pleasing sense that everything is as it should be, take the place of the more exultant and grand notions; and the muscular tremor and vocal indistinctness are now, so to speak, microscopic, but still existent, and to be appreciated by careful examination, if not at one period, certainly at another, if carefully watched for. When I first saw him he boasted of his great age; alleged he "was 80 years old (he was 38)—older than his parents; had great wealth; and no one could do the work he did". At that time his voice was more indistinct than now, and the tongue and labial muscles were tremulous and jerking. It is an instructive case. He is the type or representative of those whose physical appearance, whose well-nourished systems, had deceived and misled their medical attendants in the cases to which I referred at the commencement of my remarks; and really, as he stood unquestioned before you, who would have suspected that he was the victim of a mortal malady! His bright eye, his ruddy cheek, his well-nourished body; his strong, burly, athletic look; and his countenance, radiant with smiles, suggested the healthy peasant rather than the invalid; and yet a minute examination revealed a group of morbid symptoms. During the past three weeks his pulse has been quick; once it has been as low as 72, and twice at 74; but on the 5th instant it was at 96, and these pulsations were registered at the same hour on each day. It has ranged from the above lower numbers to this the highest, the average for the time mentioned being about 84½ per minute. His temperature has fluctuated considerably; but on the whole it has been rather above than under the mean normal standard, occasionally reaching 99.5 deg. Fahrenheit in the axilla; on the 23rd of May it was 99.8 deg., and on the 1st June 99.2; and these oscillations intimate, I think, the varying degrees of fulness of the capillary blood-vessels of the cortical substance of the brain, leading by their increasingly hypertrophied condition to the destruction of the nerve-tubes and cells of that structure.

In most cases of general paresis there is an increase of temperature as the disease advances to its fatal issue. One of the most marked cases of this disease which I have had under treatment during the past year died on the 24th May last; and in his there were in the last stages a very rapid pulse and a very high temperature, the former rising during the last week of life from 100 to 135 per minute, and the temperature in the axilla ranging from 98 to 103 deg., the latter being at 10 A.M.; on the five last days of his existence 101.4, 101.4, 101.2, 102.5, 103 deg. respectively.

I am indebted to Dr. Mickle, the assistant medical officer of the Derby County Asylum, for the thermometrical registrations, which have been taken by him twice daily with extreme accuracy in these and analogous cases. So long ago as 1839, Dr. John Davy pointed out the value of thermometrical observations in detecting latent pulmonary disease in the insane; and, from the knowledge derived from his papers, I was frequently in the habit of demonstrating to the clinical classes at Hanwell, in 1847-48, the elevation of temperature in adynamic forms of pulmonary tubercular disease—a disease often so masked by the cerebral disorder as to be latent from notice, until its presence was sus-

pected and looked for from the indications of the thermometer, there being no cough and no expectoration to excite attention. This instrument, by the researches of Wunderlich, and the experiments of Brown-Séquard and of Mr. Hutchinson on the temperature of parts after the section of nerves, promises to be of great diagnostic value in cerebral diseases, and is now extensively used in our best lunatic hospitals.

To revert to J. S.: he was pleased to speak of his excellent health; of his increase in weight; of the personal charms of his wife; his ideas on this subject resembling those tribes who regard obesity and size as the chief elements in beauty; and when he was speaking of these matters, you might have observed frequent twitchings in the orbicularis and other muscles near the mouth; and when uttering the words "pud-ding", "cowslip's wine", "stones-weight", and several others, there was the pause, or special voice-sound, in its incipient development, which was so marked a feature in the verbal utterances of T. G. His legs have not yet lost their co-ordinating power; but in T. G., you observed that the walk had become unsteady, the limbs were moved with apparent effort, and that decadence of power had commenced which will progress; the feet will be thrown out wider in the step; he will soon stagger in his gait, and retain his balance with such difficulty that, if called upon suddenly to turn round, he would fall. As the disease progresses, the ears participate in the general debility, and the head is very early incapacitated from movements requiring quick and complex movements of the muscles, as in writing or other such acts. A time comes when the patient is unable to walk: but this condition, as a rule, is not arrived at until after many months. The muscles do not waste as in ordinary paralysis; and this affection differs from paraplegia or hemiplegia in this particular, that, while these affections may remain, as it were, in *statu quo*, through long periods of time, there is in general paresis an irregular progressive diminution of power; it is irregularly progressive; yet, dating from month to month, the controlling power becomes less and less, and the strength sensibly diminished. Some observers think that the arm is affected at as early a stage as the lower extremities; but that the paralysis is more conspicuous in these, from the power required to sustain the weight of the body. After treating scores of cases, I am unable to acquiesce in this statement. Within a time, various in each individual, the muscular debility involves the whole system, accelerated much by epileptiform seizures, which occur at irregular intervals as the disease advances; deglutition even becomes difficult, and the patient runs great risk of choking; the power over the sphincters of the bladder and rectum is gone; bed-sores, despite of water-beds and every possible care, set in, and for weeks and months (unless apoplexy supervene) the patient lies a helpless, mindless, inarticulate being, and continues thus until death closes the piteous scene.

The only diseases with which general paralysis is likely to be confounded are locomotor ataxy and alcoholism. Locomotor ataxy occurs at about the same period of life, and, like general paralysis, it is more frequent in males than in females; as in it the sufferers are often descended from insane parents, and the gait in each is deeply affected; yet, the ataxy is distinguished from general paralysis by the *absence* of mental alienation, and by the *presence* of lancinating evanescent neuralgic pains which precede or usher in ataxy; by the greater deficiency of co-ordinating power in the muscular movements, the arms of the ataxic patient being commonly thrown about to preserve the balance of the body in a far more marked and oscillating manner than is seen in cases of general paralysis; by the greater capacity to endure fatigue, and especially by the muscular power manifested by the ataxic patient when in bed, or so supported that individual limbs may act apart from that consentaneousness of action which is necessary to sustain the body erect while walking; in short, it is sharply defined from general paralysis by the absence of mental alienation, and the presence of neuralgic pains in its earlier stages.

In alcoholism you have many symptoms in common, but the antecedent history, the odour of the breath, and the muscular tremulousness preceding for a considerable time the mental aberrations, will guide you to a safe diagnosis. It is well, however, to remember that alcoholism sometimes leads to general paresis.

I stated at the commencement of my remarks, that it was not my intention to give a full portrait of the disease; to describe all the phenomena of its progress; to detail its treatment; or to elucidate its pathology; but simply to illustrate by living examples the special diagnostic marks which in the earlier stages will reveal to you a disease for which no remedy is known. My tale is told. It is a sad history; but, happily, through all the earlier stages, the patient is usually cheerful and serene; indeed, in no stage does he manifest a sense of suffering, and so long as he can articulate words at all, he speaks joyously, and, to use the graphic language of Conolly, "Of all fatal maladies it seems to be attended generally with the least sense of distress". Immediate sacrifices consequent on the cessation of all exertion are disre-

garded; increasing infirmities are forgotten or unheeded; utter helplessness ensues without the consciousness of it; and the mind, with interruptions of fitfulness, is usually lively and hopeful, and even joyous. To the exalted imagination of the patients their prospects are best; their wives are the handsomest; their affairs settled in the most satisfactory manner. Their health, they thank God, is restored; their accomplishments, they do not affect to conceal from you, are boundless. With faltering speech they declare that no public singer can rival them, and when they can no longer rise from a chair, or walk without help, they express an ambition to engage in athletic competitions, to run in a race, or fight in a ring, and thus sometimes, even to the last, or as long as speech remains, they are like happy children.

"Gay Hope still theirs by Fancy led."

## OBSTETRIC MEMORANDA.

### VERY EARLY PREGNANCY.

ELIZ. G., born in June 1857, was attended by me in the end of July 1869 for symptoms which were by her attributed to dyspepsia, and by her mother to the approach of the period of puberty. She suffered from morning sickness; her breasts were full, with dark coloured areolæ; and her abdomen was considerably enlarged, without any evidence of fluctuation. Although I failed to detect the foetal heart, I gave a presumptive diagnosis of pregnancy, which was incredulously received alike by the patient and by her mother. On January 10th, 1870, she again came under observation as the mother of a fine healthy-looking child, to which she gave birth on December 18th, 1869. Conception must have taken place in the previous March, when she wanted three and a half months of being twelve years of age. The mother was an epileptic, and six of her children had been subject to epileptiform attacks in childhood; but, with the exception of this girl, they had all "grown out of the fits". She was still occasionally subject to what were described as "nervous fits", and appeared to be of rather weakly intellect. She had never menstruated, and had no recollection as to when she began the intimacy which resulted in her precocious maternity and her paramour's introduction to the hard-labour department in the city gaol.

In this patient, conception occurred at an unusually early age for this country, where, so far as I am aware, the earliest case of delivery is that recorded by Mr. Robertson of Manchester as having occurred at the age of eleven. Probably one of the earliest authenticated cases of pregnancy is that reported by Dr. Curtis in the *Boston Medical and Surgical Journal* for 1863, the subject having given birth to a child at the age of ten years and eight months.

Chester, 1871.

WILLIAM HAINING, M.D.

### MULTILOCULAR OVARIAN CYST: OVARIOTOMY: RECOVERY.

E. W., aged 33, married, had two children, the youngest 4 years old. She had never been pregnant since. Her labours and recoveries had been good. She had always enjoyed good health until May 1870, when she felt an enlargement in the left iliac fossa, unaccompanied by any pain; this gradually increased until it occupied the whole abdomen. When I first saw her, in March 1871, the swelling was very irregular, movable, and fluctuating in parts. Examination *per vaginam* showed that the uterus was drawn up, the os being almost out of reach of the finger; and a large mass was felt in the recto-vaginal pouch, pressing upon the rectum. Menstruation before the commencement of her illness had always been regular; but since that time had been constant, though scanty. Her motions were flattened, and were passed with considerable difficulty. During April and May, 1871, she was constantly troubled with violent attacks of vomiting, lasting sometimes for several days, and she was becoming very reduced and weak. On May 20th, the patient being under the influence of chloroform, the usual incision was made from the umbilicus to near the pubes, and the several structures were divided until the tumour was exposed. Several cysts were now tapped, but only a small quantity of fluid (not more than a few ounces) escaped. The incision was enlarged upwards for two inches, and several more cysts were tapped, but still the mass could not be removed. The incision had to be enlarged still more upwards, and then two larger cysts came into view; after these had been tapped, the mass was drawn forwards, and the pedicle (which was a long one) secured with whipcord well soaked in carbolic oil (1 to 5) and divided. The pedicle was secured lower down, cut off, and returned into the abdominal cavity, with a single whipcord ligature, both ends of which were

cut short off. A considerable quantity of blood and fluid was sponged out of the abdominal cavity, the omentum was drawn down and spread carefully over the intestines, and the wound brought together with six harelip pins. Carbolic oil of the strength mentioned above being applied over all, a broad flannel bandage kept the dressings in place. The only adhesions were a few slight ones to the rim of the pelvis; these were easily broken down with the hand. The patient took very little chloroform, and did not vomit once during the operation, which lasted in all thirty-five minutes. Immediately after the operation I gave her a suppository containing half a grain of morphia. Her pulse was 74, it having rarely been under 100 for two months previously. The tumour was composed of from twenty to twenty-five separate cysts, the contents of some being gelatinous, of others purulent, grumous, straw-coloured, limpid, etc. The mass when removed nearly filled a common wooden bucket.

For the second and third day after the operation, she was much troubled with tympanites, which was relieved by hot fomentations; she took nourishment well from the first, and was never once sick, nor even felt so. The needles were removed on the fifth day, the wound having entirely healed, and without the formation of a drop of pus. She took one grain of solid opium five hours after the operation, and had one-third of a grain of morphia injected into the arm until the tenth day. Catheter was used three times a day for nine days. Her pulse for the first five days ranged from 96 to 120; on the fifth day it suddenly went up to 140, and remained so for two days, after which it gradually fell again. She had at the same time an obstinate attack of diarrhoea, which no doubt accounted for the sudden rise in the pulse. On the tenth day she was carried to a couch to have her bed made, and was able to eat a piece of chicken. In less than three weeks she was able to sit up in bed by herself, and is now fast regaining her health and strength.

WILLIAM G. KEMP, L.R.C.P.Lond., M.R.C.S.Eng., etc.,  
Wellington, New Zealand.

## CLINICAL MEMORANDA.

### CASE OF A CHILD SWALLOWING A LARGE NUMBER OF PLUM-STONES.

ON the evening of October 18th, I was called to see a little girl 2½ years old, who the day previous had swallowed a number of plum-stones. At my visit, I removed from her rectum by the finger 116 of these bodies. Previously to my seeing her she had passed three of them, and four escaped after my visit, making in all 123. The rectum was enormously distended; and there being almost no fecal matter, the sharp edges of the stones caused considerable bleeding and irritation during their removal. The next day the child was quite well.

Middlesbrough, Oct. 21st, 1871.

W. KETCHEN, M.D.

### THE DURATION OF VACCINE PROPHYLAXIS.

How long does the prophylactic influence of vaccination extend? The following cases, which have recently occurred in my practice, bear upon the question.

CASE I.—S. J. A., aged 20, five years ago took cow-pox from milking infected cows. She had the eruption in her arms, chin, chest, and back. She showed me a cicatrix on the arm, and one beneath the chin; the latter resembling that produced by vaccination. On August 16th, 1871, I revaccinated this patient in three places, cross-cutting with a lancet. All three were successful.

CASE II.—On Aug. 25th, 1871, I was called to a child aged 5 years and 9 months, who had small-pox. On the arm were three good primary vaccination-marks, the operation having been done in infancy.

CASE III.—On July 20th, 1871, I attended H. G., an adult, suffering from small-pox. He told me he was successfully revaccinated in the early part of 1866. In both these cases the disease was modified.

From these cases I should limit the time of the prophylactic influence of vaccination to five years. In proof that revaccination does really possess a prophylactic power, though the time during which it exerts that power is finite, I may add that, during the present epidemic, I have successfully revaccinated at least 410 persons. Out of this number one only had small-pox subsequently. In this patient I saw the variculous eruption ten days after the operation. I had revaccinated him on account of his having been exposed to small-pox infection, and there can be little doubt that at the time of the operation he was already infected. The disease was modified. My experience as regards the prophylactic influence of revaccination is, I believe, shared by most

of my professional brethren in this town. During the present epidemic, I know of no instance of small-pox occurring in persons who had been successfully revaccinated three weeks before the appearance of the disease.

WILLIAM V. LUSH, M.D. Lond., F.R.C.S. (Exam.)  
Weymouth, October, 1871.

#### NOTE ON EXCISION OF THE TEETH.

THIS operation may be practised with great success, provided the necessary precautions be observed. Its more general adoption was formerly much retarded, owing to their being neglected. Previously to 1826 the *modus operandi* was tedious and painful, the saw and file being the instruments made use of; but since that date the operation could be instantaneously performed by means of excision-forceps invented by Mr. Fay. Excision, in appropriate cases, possesses certain advantages over extraction. It admits of the immediate insertion of artificial teeth; and the stumps, retained in their sockets, help to maintain the natural form of the mouth and strength of the arch, and are useful for mastication. The single-fanged teeth are best adapted for the operation. Caries ought not to have extended beyond the body; and the roots and adjoining tissues should be healthy. If the pulp be not withdrawn with the excised portion, it must be subsequently removed, otherwise the fangs will probably ache and periostitis may supervene. I find that the most effectual method of eradicating it is the actual cautery, which gives but momentary pain. A heated platina wire answers the purpose very well, for, being pliable, it may be introduced even to the extremity of considerably curved fangs. A fine unheated drill may be used, but it causes more pain and can only be employed when the fangs are straight. When neither of these plans is applicable, an escharotic should be applied. Sometimes after a few years the fangs start from their sockets, but this does not happen in the majority of cases, and need not be urged as an objection to the operation, for the evil may be speedily remedied by a few passages of the file over the offending stump.

TULLIUS W. W. FAY, M.R.C.S.E., Dental Surgeon to the  
Liverpool, October 19th, 1871. Liverpool Dental Hospital.

#### RUPTURE OF THE LEFT VENTRICLE OF THE HEART.\*

THE patient died at the age of 59, after twenty-four hours' severe pain in the chest. The actual time at which the rupture took place was not known; but possibly it was caused by the act of raising the body from the recumbent posture. There was but little history of previous discomfort, save, perhaps, an unwillingness to make much exertion. The body generally was well nourished; the omentum was loaded with fat; the right pleura was adherent throughout. The pericardium contained a large clot and much serum. The heart was somewhat fatty externally; at the anterior part of the ventricle, near the apex, was a discoloured spot, much like an ecchymosis, and in the centre a small rupture a quarter of an inch in length. The surface of the ventricle inside corresponding to the seat of rupture was covered by layers of fibrine something like the interior of an aneurism, as if it were an effort of nature to stop the leak. The walls of the ventricle were almost wholly converted into fat, and tore like blotting-paper. Under the microscope, there were found to be an abundance of fat-cells and great deficiency of muscular fibre. The small opening and the layers of fibrine inside seemed to account for the duration of life after rupture, and thus a somewhat lingering death was the result, instead of the usual sudden death caused by rupture of the heart.

JAMES THOMPSON, M.D., Leamington.

\* Read before the Birmingham and Midland Counties Branch.

**POISONING BY CANTHARIDES.**—The *Repertoire de Pharmacie* for September 1871 quotes from the *Bulletin Médical Militaire* a group of cases of poisoning by cantharides, drunk accidentally in alcoholic tincture. The principal symptoms were painful efforts at defecation and micturition, with expulsion of scanty and sanguinolent urine and red and glairy matters; swelling, heat, and pain of the penis, and tenesmus without erection or venereal desire; pallor, sweat, and expression of anguish, with general injection of the conjunctivæ; heat and sense of constriction of the throat, epigastralgia, and bilious vomiting; cerebral agitation and exaltation of sensibility. The treatment was by emetics, prolonged warm baths, camphorated opiate emulsions, decoctions of linseed, emollient oily enemata, opiate cataplasms. The patients all recovered. Some suffered from albuminuria, incontinence of urine, or even more or less pronounced paraplegia.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

#### KING'S COLLEGE HOSPITAL.

##### REMOVAL OF FUNGOID TUMOUR IN THE UPPER ARM: CLINICAL OBSERVATIONS.

By Sir WILLIAM FERGUSSON, Bart.

THE first operating day after the autumn holiday is generally a field-day in the hospitals of the metropolis. On Saturday week, October 14th, we were attracted to King's College Hospital by the announcement of the above case for operation by Sir W. Fergusson, among others of minor interest. The patient, J. M., aged 34, a sickly-looking man, showed great anxiety to have his tumour taken away, and with alacrity leaped on the operating-table. A large fungous mass, of about the size of a cocoa-nut, was situated near the shoulder. The knife was swept around it, and the bulk of it removed; but it required very careful dissection for ten or fifteen minutes to separate its connexion with the biceps and other structures about the joint. After a few arteries of no great magnitude had been tied, and others pinched, the wound was closed, and the patient removed to bed. Sir William Fergusson then made the following remarks.

This is a case, gentlemen, peculiar in a variety of aspects. This patient was born with certain tumours upon him; and at that time he was seen by some of the first men in the profession in England, who all doubted the propriety of interference, because they were uncertain as to the character of the tumours. There was one particularly near the left eye, and another under the clavicle, and both of such magnitude that the patient was looked upon as one not likely to live long. But the child lived to boyhood, and the boy grew up to manhood; and twelve years ago he came under my notice. I decided as to the character of both the tumours; and both were removed with facility, and without subsequent evil. He had then a number of molluscous tumours about him, but these were not meddled with. One of them, on his arm, however, increased so much in size that it was removed five months ago. It was of the size of a walnut. The disease returned in the cicatrix, and has in that brief time—since May last—grown to the size you saw. I had the privilege of seeing him last week, as I took a special interest in the case, and considered that the disease was likely to prove serious. It would have been a pity to have subjected him to amputation of the whole arm, because it was perfectly healthy save this fungoid tumour. It struck me that the tumour might be removed; and I gave that advice, and was prepared to operate. But I was also prepared to amputate if necessary—if the tumour involved the other tissues in the neighbourhood. I had doubt about it, and thought that it certainly did involve the biceps. I could scarcely think that it involved the brachial artery and nerves; if it did, amputation was the only resource. Now, on proceeding with the dissection, it did not give much promise at first; but the biceps muscle I recognised early in the operation, and saw that the tumour was attached to the outer and back part of it, and that I could save a large proportion of the muscle. I cut through its aponeurosis; and then a careful dissection enabled me to take out the larger portion of the tumour. It then became apparent that the deeper part of the tumour was to the outer side of the brachial artery and nerves, and so I proceeded with much more freedom. Looking at the health of the patient, I may say that the prospects are not specially good; but yet there is the arm now without an unsound tissue upon it, and without any structure of importance taken away. Even supposing this to be a malignant tumour, amputation itself would have afforded, perhaps, no better prospect than the partial removal which you have now seen.

#### MIDDLESEX HOSPITAL.

##### CASES OF CANCER TREATED BY CONDURANGO.

(Under the care of Mr. HULKE.)

*Ulcerated Epithelioma of the Roof of the Mouth.*—H. L., sixty-eight years of age, a short, thin, wiry-looking stable man, was admitted into Handel Ward on the 17th August, 1871, with an ulcerated tumour of the roof of the mouth. On admission, the tumour involved the entire left half of the roof of the mouth, implicating the hard palate and velum, and also the right half of the velum, extending in this direction as far as the right anterior faucial pillar. It had a nodular surface, and depended

from the alveolar border of the maxilla in curious wattle-like masses. The centre was irregularly eroded by ulceration. The floor of the ulcer was partially coated with tawny yellowish films, amongst which were nodules of growing tumour, and red clusters of granulations. No enlargement of the neighbouring lymphatic glands was discoverable, and there was no appearance of cachexia. On the contrary, the patient's aspect was that of sound health. The present affection commenced a year ago, as a small warty lump, in the situation of a wound caused by the pipe which he was smoking being driven against the roof of his mouth. The growth had been twice excised in another hospital. On admission, a weak gargle of myrrh, and a liberal diet, were ordered; and, on the 25th August, he began to take five ounces of decoction of condurango night and morning, and continued to do so till September 26th. During this time, the tumour continued to grow, and the ulceration to spread; they now extended into the fauces, and the left cheek bulged outwards. Deglutition became increasingly painful and difficult, and at times he had chokings; during the last fortnight, there had been several small hæmorrhages from the ulcer. He latterly rapidly lost weight and strength, and his expression on September 27th was sallow and cachectic.

*Primary Cancer of the Penis, and Secondary Infection of the Lymphatic Glands in both Groins.*—J. P., thirty-four years of age, a haggard, pain-worn man, was admitted into Handel Ward on the 15th August, 1871. The end of the penis where the glands had been was an unsightly tuberculous mass, partly ulcerated, and partly granulating. A large ulcer reached from near the left anterior superior iliac spine, along the groin across the pubes, measuring seven by two and a half to three inches in its long and short diameters. In its outer half, growth preponderated over ulceration, and its floor was studded with cauliflower buttons and masses of small granulations, while at its pubic end the erosion was so deep that it seemed surprising that the peritoneal cavity was not opened. The edges of this ulcer were very irregular and sinuous, in parts undermined and overhanging, in other parts swollen and everted. Near the outer end of the ulcer were some small outlying buttons. The lymphatic glands in the right groin were enlarged and indurated. The discharge was very profuse, thin, ichorous, and nauseously fetid. No very clear history could be obtained from the patient; he said that the malady began as a wart on the penis. A solution of chloralum was used locally to destroy the horrible fætor. On the 24th August, he began to take five ounces of decoction of condurango, night and morning, and continued to do so till the 16th September. The growth progressed steadily; the small outlying buttons in the left groin became large cauliflower masses. The ulcer spread largely in area and depth; and on the 16th September, it took on a sloughing action, and the patient died exhausted on the 19th.

Condurango was administered in two other cases; one of these was a case of ulcerated scirrhus in the female breast; the other an ulcerated epithelioma of the scrotum. Owing to the limited supply of the plant, its administration had to be discontinued in these two cases on the fifth day; the results so far were, however, similar to those in which a full trial had been made, the progress and character of the malady remaining unchanged in every way.

### LEEDS GENERAL INFIRMARY.

#### ALTERNATING HEMIPLEGIA: WITH CLINICAL REMARKS.

By J. D. HEATON, M.D., F.R.C.P., Senior Physician to the Infirmary.

SARAH FROST, aged 27, married, was admitted June 22nd, 1871. There was no evidence of rheumatism or syphilis; no previous heart-symptoms nor head-affection, except occasional headache. She had enjoyed good health till three months before admission, when her left eye began to droop, and this increased till she lost all power over the levator palpebre, the eye being habitually closed. She could see when the lid was raised by the finger; but gradually the sight also of the left eye failed; the right eye remained perfect in all respects. About a month after the commencement of these symptoms she had "a stroke" in the night, so that, on attempting to rise in the morning, besides having severe pain in the head, she found that she had lost the use of the right arm and leg, and she was also aphasic. She kept her bed for a month after this, under medical treatment, gradually recovering power, so that she could then walk feebly, and had partly regained her speech, but the right hand remained paralysed. During the last month she had made very little improvement.

*Condition on Admission.*—Her general health and appetite were moderately good. She was low-spirited, and cried and laughed hysterically when spoken to. She spoke with some effort and hesitation and indistinctness, being sometimes at a loss for words, but was quite intelligent. The left eye was permanently closed, the levator palpebre muscle

being paralysed; the pupil was irregular, dilated, and non-contractile; the sense of sight in this eye was reduced to a perception of light and darkness; the eyeball was everted, and had very little motion; the right eye was perfect in all respects. The right side of the face was paralysed, the face being drawn to the left when in motion. The tongue turned to the right when protruded. The right arm was hemiplegic; she could feebly raise the fore-arm from the bed, but had scarcely any movement of the fingers. She had a feeble power in the right leg, so that she could limp across the floor. Tactile sensation was perfect in all parts. The cardiac sounds were normal.

The treatment consisted in the administration of iodide of potassium and faradisation of the affected muscles, which feebly answered to the stimulus of the electric currents. At the expiration of a month she left the Infirmary, by her own desire, without any improvement.

*CLINICAL REMARKS.*—In this case there are symptoms of disease located in the left hemisphere of the brain; viz., aphasia and right hemiplegia of the parts innervated by spinal nerves; and hemiplegia, also of the right side of the face, which receives its supply from cranial nerves. The facial hemiplegia usually belongs to the same side as that of the body, but not invariably so, for the "cross effect" of cerebral disease, although the constant rule as to parts supplied by spinal nerves, is subject to occasional exceptions (as it is also less explicable) in the face, which is sometimes paralysed on the side of the disease in the brain. Out of 38 cases of paralysis of the face connected with cerebral disease recorded by Burdach, 10 were on the same side as was the disease in the brain; 28 were on the opposite side. In this case, the motor portion of the fifth cerebral nerve and the ninth cerebral nerve on the right side have lost their power. It is not very easy to say whether the portio dura of the seventh nerve is also affected. The branches of this nerve inosculate with the motor branches of the fifth nerve on the side of the face, and probably some interchange of filaments is effected; but, as the orbicularis palpebrarum muscle, which is innervated by the portio dura, retains its power, this nerve is probably unaffected. But, in addition to these customary results of disease in the left hemisphere showing themselves in the right side of the body and face, there is also, in this case, loss of function of parts situated on the left side of the face, being the same side as that in which we conclude the disease of the brain to be located. The left eye is amaurotic; the sensory optic is paralysed, and so is the third nerve, the motor nerve of the eye; the left eyelid cannot be raised, and the ball of the eye has lost its motion; but the sixth cerebral nerve retains its functional activity, so that the external rectus muscle, to which it is distributed, draws the eye permanently outwards, being no longer counterbalanced by the other muscles in the orbit.

Such are the parts at present, and, it is to be feared, permanently, deprived of functional activity by the cerebral lesion. It is to be observed that the first overt symptoms occurred in the left eye, and these are permanent and have become more intense. Subsequently the more customary train of symptoms of left cerebral lesion were developed; viz., aphasia and right hemiplegia of both face and limbs. All these latter symptoms have been ameliorated, but not removed.

Alternating hemiplegia, as it is sometimes called, which is exemplified in this case, is not, I think, of very common occurrence. It might be attributed to coexisting lesions in both hemispheres; but I am inclined to think that in this case all the symptoms are the result of disease in the left hemisphere. The direct effect of such lesion on the left eye is quite anatomically probable; and the aphasia and the cross effect shown in the other symptoms are all in accordance with our every-day experience of the results of such lesion.

The remarkable feature in the case is the combination of direct and cross effects upon the nerves and the organs which they supply. But we know that the intracerebral continuations of several nerves have been anatomically traced into the hemisphere opposite to that of their superficial origin; and the actual intercommunication and connexion of structure and function in the finely tubular tissue of the white substance of the brain doubtless far surpasses anything that the eye of the anatomist can ever demonstrate.

It has been said that alternating hemiplegia occurs as the result of disease in the pons Varolii, and we could well understand how a lesion situated in this great central mass or commissure might distribute its effects to the right hand and to the left; but, in fact, the connection of alternating hemiplegia with disease of the pons is not constant, neither does it seem to be a theoretical necessity.

As to the exact nature of the change of structure in the brain, there is nothing to lead to any positive diagnosis. Embolism of an arterial branch is a not uncommon cause of cerebral disease occurring in persons who have not yet passed the prime of life; but there is no history of any previous cardiac mischief, and the heart's action is at present natural and free from valvular murmur. The symptoms are not those

of chronic meningeal inflammation of the base of the brain, nor would such affection explain the coexisting aphasia. There is no history nor present appearance of constitutional syphilis. Hemiplegia, apart from other apoplectic symptoms, does not often prove fatal in young persons, so that we rarely have the direct evidence afforded by *post mortem* examination of the exact nature of the coexisting lesion in the brain.

The results of treatment are entirely negative. In the absence of any evidence of active disease in the brain, a course of iodide of potassium and faradisation of the paralysed muscles constitute the treatment upon which I should most rely. These measures were practised, without any results, up to the time when our patient voluntarily left the infirmary. Although we have frequently very satisfactory results from the treatment of paralysis of various forms by faradisation, yet many cases prove insusceptible of benefit by this as by other modes of treatment; and the improvement experienced is often attributed to the direct effect of electrical treatment which may have been really due to the *vis medicatrix nature*.

It may be worthy of note that considerable improvement had been effected in this particular case before her admission to the Infirmary. This we regard as spontaneous, the treatment meanwhile having been merely negative; whereas, had this patient come to the Infirmary soon after her seizure, and been then subjected to galvanism, the subsequent improvement would have been most probably attributed to such treatment.

### ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

LOCOMOTOR ATAXY IN A YOUNG MAN AGED EIGHTEEN YEARS.

(Under the care of Dr. BRADBURY.)

M. C., of no occupation, was admitted May 31st, 1871. He stated that he was eighteen years old, but he did not look more than fourteen; there was no history of syphilis. His illness commenced three years ago with pain and great weakness in the small of his back, these symptoms being aggravated whenever he took cold. Nine months ago, he began to lose control over his legs. His gait was very characteristic of ataxy. If he walked, he staggered as if intoxicated. His legs were thrown out at random, and he brought his heels heavily to the ground. He could not walk when his eyes were closed, without falling on the floor. When he stood upright, with his feet together and his eyes blindfolded, he fell to the ground. There was slight convergent strabismus (which afterwards became more marked), and he complained of a mistiness before his eyes. The pupils were natural, and there was no injection of the conjunctiva. He was rather deaf in the left ear. He complained at times of frontal and occipital headache, and vertigo. He had been sick on five or six different occasions in a morning. He did not complain of numbness in his legs, and had not the sensation of walking on air-bags or sponges. He could feel a prick most distinctly, and could appreciate differences of temperature. The muscles of the legs had not wasted. When he was first admitted, there was some slight loss of power at the left arm, but this has now (October 11th) passed away. Some months ago, he was troubled with pains of short duration, which shot down his legs. They were not severe. There has been no loss of control over the sphincters, with the exception of slight dribbling of urine at one time. There is no spinal curvature. He acknowledges that he has practised masturbation to a great extent since he was nine years old. He is now troubled with spermatorrhoea. The nurse says that a brother who came to see him has a peculiar gait. His legs cannot be flexed or extended against his will. When his eyes are closed, and he is told to touch the tip of his nose with one of his forefingers, he touches his cheeks or the sides of his nose. When the soles of his feet are touched, there are marked reflex movements. There is no impairment of the mental faculties.

In some clinical remarks, Dr. Bradbury said that this case was interesting in several respects. In the first place, it was, in his judgment, an instance of locomotor ataxy occurring in a person under twenty years of age; and he was not aware of more than three such cases having been published. They are recorded by Professor Friedreich of Heidelberg; and the ages of the patients were 15, 16, and 18 respectively (Friedreich, *Ueber Degenerative Atrophie der Spinalen Hinterstränge*; Virchow's *Archiv für Pathologische Anatomie*, Nos. 26 and 27, 1863). The exciting cause of the ataxy was probably excessive onanism; but there is reason to believe that a predisposition to this neurosis existed in the patient, as his brother, and, it is stated, his mother also, are subject to a somewhat similar complaint. The peculiar pains characteristic of locomotor ataxy were not well marked in this case, the patient not having volunteered the statement that he had suffered from them. There was little, if any, diminution of tactile sensibility. The headache, vertigo, and sickness, were more symptomatic

of cerebellar ataxy; but Dr. Bradbury was of opinion, taking all the symptoms into consideration, that this was not the nature of the case. Various remedies have been tried in this case, including the iodides and bromides of potassium, phosphoric acid, nux vomica, cod-liver oil, nitrate of silver, iron in the forms of citrate and tincture of the perchloride, blisters to the neck, and blistering fluid to the prepuce. Some amendment seemed to result from a mixture of phosphoric acid and tincture of nux vomica given in combination with cod-liver oil. Whilst taking nitrate of silver in doses of a quarter of a grain twice daily, the patient became much worse.

## REVIEWS AND NOTICES.

THE SCIENCE AND PRACTICE OF SURGERY. Illustrated by 470 Wood-engravings. By FREDERICK JAMES GANT, F.R.C.S., Surgeon to the Royal Free Hospital, etc. Pp. 1265. London: J. and A. Churchill. 1871.

A NEW work on this large scale, professing so to represent the science and practice of surgery as to give a full embodiment of all established changes in the pathology and treatment of injuries and surgical diseases, excites admiration of the ambition and perseverance of the author. The surgeon who undertakes the task at this time and in this country, in the face of several formidable rivals who have long occupied the field, must possess no small share of the *robur et as triplex*. He challenges at the outset the decision whether such a work was wanted; and whether he has succeeded in supplying the want.

In the opening sentence of his preface, Mr. GANT says that "it is now many years since a new systematic work representing the science and practice of surgery has appeared in this country". If this mean only that Mr. Gant is the first surgeon who has for a number of years past appeared *de novo* as the author of a systematic work on surgery, it is a technically correct statement. It somewhat, however, ignores the fact that the authors of well-established works on the subject have from time to time within recent years prepared new editions, of which one is only just completed, and in each of which important additions and corrections have been made in order to bring the books up to the last results of surgical science. Does the present weighty tome approach the standard of perfection more closely than any other that now exists?

Mr. Gant claims for himself the great merit of having brought the importance of pathology in relation to surgery prominently before the notice of British surgeons. In an introductory chapter he says (page 5) that "the contrast between the continental and the English schools of surgery mainly turns on the more intimate incorporation of pathology with operative surgery"; and he remarks that, while this incorporation has been taught by the French, German, Italian, and American surgeons, it has been more slowly recognised in England—the only systematic surgical writers who have recognised it being John Bell (1801), Liston (1846), Fergusson (1852), and Skey (1858). He goes on to tell us that in 1864 he brought forward the guidance of pathology in surgical operations as a general principle; and, after some remarks on the subject, he proceeds to apply the principle by giving a general outline of the conditions favourable and unfavourable for operations. We cannot altogether agree with him as to the comparative merits of British and continental surgeons in their relative appreciation of the value of pathology as applied to surgery; nor is it possible to concede his claims of having been the first to summarise the general conditions on which the success of operations depends. As in his preface he acknowledges having consulted Mr. Erichsen's *Science and Art of Surgery*, and makes various quotations from it in the course of his work, he should not have forgotten that, in the several editions of this book which have appeared during the last eighteen years, the author has specially described the "Conditions influencing the Success of Operations", and has insisted most strongly on the fact that manual skill is not sufficient, but that attention to pathological conditions is indispensable to the success of operations.

Our author further enumerates certain of his "own pathological observations and surgical experiences" as being interspersed throughout the work. Among them, are "the pathological conditions of contused and lacerated wounds, of compound fractures, and of compound dislocations, which severally require amputation". On carefully examining the passages in which these subjects are treated of, we are unable to find anything beyond what has been for years past quite as clearly and well taught by Mr. Erichsen, whose very words, indeed, are largely appropriated by Mr. Gant, especially in regard to compound

fractures. Neither as regards the general rules as to the conditions under which amputation is required, nor as to the necessity of attending to the circumstances which may modify the surgeon's acceptance of these rules in any given case, can we find that Mr. Gant has advanced any novel views or added an iota to the stock of surgical knowledge. Another of the subjects to the improvement of our knowledge of which Mr. Gant lays claim, is that of the excisional surgery of the joints; and it is but fair to say that this subject appears to have been most carefully studied by him, and that his chapter on it (which embodies a course of "Lettsomian Lectures" delivered by him before the Medical Society of London), is very complete and instructive.

In his preface Mr. Gant, as we have seen, acknowledges his indebtedness to the various standard surgical works. Most prominent among these are, besides Mr. Erichsen's book, a number of the articles in Mr. Holmes's *System of Surgery*; and we find, on making a careful comparison of several of the chapters in Mr. Gant's book with the corresponding articles in these works not only that in many instances there is a striking similarity of expression, but that the author of the present work has made little if any material addition to our knowledge in respect of the several subjects. Had our author availed himself of the new edition of Holmes's *System* before finishing his manuscript, he could have still further improved his book by laying the volumes of that edition under contribution to the same extent as the first *System*. Thus we find here no reference to the observations of Billroth and others on traumatic fever; and, while Mr. Gant derives a large amount of his information on gunshot-wounds from Mr. Longmore's article in the second volume, his statistics do not include the latest of those given by the last-named author. The last volume of the new edition of the *System of Surgery* probably appeared too late for Mr. Gant to avail himself of it; and this is the more unfortunate, as he has lost the opportunity of making use of Dr. Burdon Sanderson's admirable exposition of the modern doctrines of Cohnheim and others regarding inflammation, which form an essential point of that advanced pathological knowledge on which our author justly lays stress.

There are various contributions of high value that have appeared in recent years, but which, from oversight or from their not having appeared in time, have hitherto not been noticed in our systematic surgical works. Among those which occur to us at the moment are, Mr. Hancock's article on the perforating ulcer of the foot (see *BRITISH MEDICAL JOURNAL*, June 26th, 1869); Dr. Bigelow's account of the mechanism of dislocation of the hip-joint; Mr. Furneaux Jordan's prize essay on shock, published four years ago in this *JOURNAL*; articles on the removal of tumours by electrolysis; cases of ligature of the abdominal aorta by Mr. McGuire and Mr. W. Stokes, etc. Any reference to these we search for in vain in Mr. Gant's book.

At the end of the book is "a carefully compiled index". On examination, we find this to bear very distinct traces of having been apparently made in a rather extraordinary manner; viz., by adopting almost wholesale the index to the last edition of Erichsen's *Art and Science of Surgery*, and altering it to suit Mr. Gant's book. Our reasons for arriving at this conclusion are: that the mode of arrangement is precisely the same; that Mr. Gant's index contains derivations of surgical terms identical with those given in the last edition of Mr. Erichsen's work; while in the case of some words, such as "acritochromacy," "agalactia," "amaurosis," "mastitis," "mydriasis," which occur in Mr. Gant's index alone, the derivations are not given. *En passant*, Mr. Gant or the compiler of his index has made a rather absurd mistake: while adopting the incorrect spelling "phymosis" and "paraphymosis," he retains the derivation from  $\phi\mu\sigma$ , a mouse.

In conclusion, we must express our conviction that, though it is no doubt possible to produce a better work on systematic surgery than any which we now possess, Mr. Gant has distressingly failed in the endeavour to produce such a book. *Magnus exultat error*. His *Science and Practice of Surgery* is not, so far as we have been able to discover by careful examination, one whit more instructive in regard to principles, and very rarely so in regard to details, than other books of the same kind which have for some time been in the hands of the profession. Mr. Gant is, we believe, an able surgeon, and is evidently desirous of taking his share in the improvement of that branch of our profession to which he has devoted himself. In writing a systematic work on surgery, he has mistaken his vocation; but, if he will apply himself to the investigation of some of those surgical problems which yet require settlement, it is still open to him to bring credit to himself and benefit to his profession. In the great task which he has set himself in this work he has failed; but it is one which might easily overtax greater powers than he has proved himself to possess. The attempt is honourable; and even the failure is far from being discreditable.

A DESCRIPTIVE CATALOGUE OF THE CALCULI AND OTHER ANIMAL CONCRETIONS CONTAINED IN THE MUSEUM OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND. By THOMAS TAYLOR, F.R.C.S. Pp. 87. Taylor and Francis, London: 1871.

THIS is an interesting and valuable addition to the catalogues of the Hunterian Museum, by a gentleman eminently qualified to complete the work entrusted to him some years since by the Council of the Royal College of Surgeons. It forms the first supplement to the volumes already published. Great credit is due to the Council for the admirable selection of such men as Owen, Quekett, Morris, Cobbold, Stanley, Paget, Flower, Bader, Taylor, and Wilson, to compile these catalogues on subjects regarding which each contributor has special acquirements.

In the catalogue under notice, the medical officers of Her Majesty's Indian Army are conspicuous, not only by their numerous and valuable additions to the Museum, but by the great success attending their operations in lithotomy. Mr. H. C. Cutcliffe, a Fellow of the College, appears to have given his entire collection. Messrs. Thomas Atchison, W. E. Allen, Beatson, etc., of the same service, have been most liberal. These calculi are of great interest as illustrating the effect which diet and habits of living have upon the composition of these concretions, and also because, in almost every instance, they are accompanied by a statement of the age and sex of the individual from whom they were taken, the duration of the malady, and the progress and result of the operation.

Members of the Council past and present have also largely contributed to this valuable collection, especially the late Mr. Hodgson, who presented his large museum of calculi; among the donors we also find Messrs. Cock, Curling, Spencer Wells, Luke, Mackmurdo, Hilton, Bransby Cooper, Busk, etc. Messrs. Ceely, Pilcher, Roberts, Barker, Bird, Parker, Sir Duncan Gibb, and others, who show the great interest which they take in the Museum by contributing to its riches.

During the twenty-six years that have elapsed since Mr. Taylor's former catalogues, 356 specimens of calculi from the urinary organs of man have been added, making with the former a total of 1,005.

Of rare calculi, the most remarkable additions to the Museum are the half of a xanthic oxide calculus, consisting chiefly of carbonate of lime taken from the bladder of a man, and presented by Mr. Bird, of York. Of the latter species of calculus, the collection formerly possessed no specimen, although, on account of its great rarity, drawings of some carbonate of lime calculi in the possession of Mr. R. Smith, of Bristol, were published in a former catalogue.

Mr. George Cooper, amongst other calculi, sends a large uric acid calculus, which, at the present time, weighs two ounces seven drachms, and consists of a mixture of uric acid and urate of ammonia, but containing very little earthy matter. The following quaint account of the specimen accompanied it. "Cut from James Clitherow, of Boston House, 13th of August, 1680, then aged 62; he died November 25th, 1682." The statement of the expenses attending the operation is curious; it was taken from his book, and sent with the calculus. "To £150 paid by agreement to Monsieur Callot ye Frenchman for cutting me of the stone. To Apothecary, Surgeon, and Nurse that attended me, £26 10s. 6d. For rent of my lodgings in Hatton Garden and diet there, £28 15s. 2d. For a pallet bed and ye furniture of it then used, £6 17s. For charges of removing to and from London, £1 10s. Making a total of £213 12s. 8d."

AN INTRODUCTION TO PATHOLOGY AND MORBID ANATOMY. By T. HENRY GREEN, M.D., Lecturer on Pathology and Morbid Anatomy at Charing Cross Hospital Medical School. London: Henry Renshaw, 1871.

THE tedious and not very profitable task of producing a manual of Pathology and Morbid Anatomy, has just been completed by Dr. T. H. GREEN, lecturer at the Charing Cross Hospital Medical School on the subjects of which his book treats. It has been a matter of much inconvenience and a serious drawback to the study of pathology in our schools, that since the promulgation, publication, and in large measure the acceptance, of Virchow's views on cellular pathology, no one in this country has been found to undertake the labour of collecting the current views on the science. This, no doubt, is chiefly explained by the rapidly transitional state of the subject rendering it difficult to prepare a work and pass it through the press, before its contents are already behind the time. This remark is particularly applicable to comprehensive treatises on pathology. The author of the present volume, however, has limited himself to the elements of pathology and morbid anatomy, his object being to give a brief account of the more important morbid processes which take place in the human body in accordance with the present position of pathological knowledge. He accordingly first describes the

general pathology of each process, and subsequently the same process as it occurs in the several organs and tissues of the body.

In fulfilling his task Dr. Green has naturally exercised a considerable amount of caution when dealing with many important morbid processes about which pathologists as yet widely differ, and he has been content to satisfy himself with noticing the more prevalent notions; while, at the same time, it is abundantly evident that the author is thoroughly conversant with the most advanced opinions, both British and foreign, on the subject of pathology and morbid anatomy.

The volume is freely illustrated with woodcuts, some of them from the author's own preparations, the majority, however, being reproduced from Rindfleisch's *Lehrbuch der pathologischen Gewebelehre*. We congratulate Dr. Green on the measure of success with which he has completed a not very easy task. He has presented us as nearly as possible with a concise and handy elementary work on human pathology and morbid anatomy, and we hope that it will meet with the favourable reception which its usefulness certainly deserves.

## REPORTS AND ANALYSES

### MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

#### NOTE ON WINES.

THE French Academy of Medicine has devoted itself during two sittings in this month to the discussion of the question of the use of wines and spirits from the medical point of view. M. Bergeron has reported in the name of a commission specially appointed, and the Academy, after debating on their very able report, has determined to secure for it a wide popular circulation. The Academy takes precisely the view which we have taken on former occasions in considering this question. It demonstrates at great length that it is by quitting the use of the cheap light wines of the country, and by adopting the dangerous, seductive, and powerful stimulants, such as cassis, petit môle, and cider and brandy, that the French population is declining into drunkenness. In our own country the place of these drinks among the working classes is taken by gin, rum, and strong beer.

A great and beneficial change has already been evoked in the habits of our upper and middle classes by the more extended introduction of a variety of light wines of varied and unimpeachable dietetic value. It seems to be the tolerably unanimous opinion of medical practitioners of this day, that the existing type of diseases is one of prostration and debility, and that the most successful basis of treatment is by the tonic and restorative methods. Thus, in hospital no less than in private practice, the prescription of stimulants has taken a constantly increasing development.

The reduction of the wine duties has been a great boon here, as not only has it had the effect of doubling the consumption of wine within the short space of ten years, but it has made light wine—what it should undoubtedly be—an article of daily and ordinary consumption, and far less liable to be taken in excess than when wine was a highly stimulating and costly luxury. At the present time, the facilities for obtaining cheap and wholesome wines and other stimulants, bearing the guarantee of large and respectable dealers in almost every town and village, is an advantage which deserves to be kept in view.

Cheap wine has no doubt a certain amount of prejudice yet to overcome, and the medical man may do much in assisting to dispel this. Cheapness in wine does not necessarily argue a deficiency in stimulating and nourishing qualities, still less unwholesomeness. The fact is, and it is important that this should be borne in mind, that the cheap wines of the present day were only a few years ago, though identical in quality and description, sold at prices very nearly double those of the present time. How this has been brought about by increased supplies, and the opening up of new districts and countries, it would not be difficult to show. Suffice it to say that, of the three principal wine-producing countries, viz., Spain, Portugal, and France, our home consumption has increased during the last ten years from 5,877,506 gallons in 1860 to 13,373,725 gallons in 1870, the quantity of wines from Spain alone being 6,269,325 gallons in 1870 against 2,975,769 gallons in 1860.

In our issue of the 7th January last we touched upon the article sherry, and drew attention to the important place occupied by Spain as a wine-producing country. Since that time we have continued to use opportunities of testing and comparing the relative qualities and prices of various sherries offered for sale, and have been especially struck by some light, delicate, pale sherries obtained from the Messrs. W. and A.

Gilbey of Oxford Street. We think it due to the commercial enterprise, and a fair recognition of the undoubted benefit which this firm has conferred upon medical patients in the introduction of sound wholesome wines at moderate prices, to say that some of these sherries approach nearer to our idea of what a good, generous, stimulating wine should be than anything we have seen for some time past, while the price places them within the reach of all when required for medicinal and dietetic purposes. We refer to this firm, now the largest in the trade, in order to illustrate the facts as to the facilities for obtaining cheap wines now as compared with only a few years ago, for it is certainly within our recollection when wines such as these could not be obtained under double the price.

#### VULCANITE INSTRUMENTS FOR ASCERTAINING SPECIFIC GRAVITY.

MR. BLAISE (Savigny and Co.), 67, St. James Street, has for some time occupied himself with the adaptation of vulcanite to the manufacture of urinometers, alcoholometers, saccharometers, hydrometers, and other instruments for indicating the density of liquids; and he finds, after repeated trials and tests, that it is better suited to the construction of the above-named instruments than either glass or metal. Vulcanite is perfectly proof against all kinds of acid except bisulphide of carbon. The instruments do not get out of order, or break, if used with ordinary care; whereas a very slight tap will break those made of glass, or a fall will injure those made of metal, which are also apt to corrode. Moreover, the vulcanite instrument takes the specific gravity much more quickly than one made of glass or metal, and is more durable and cheaper than either. Mr. Blaise owes to Mr. Pollock, of St. George's Hospital, the valuable suggestion of adapting vulcanite to the manufacture of these instruments.

Dr. Noad, F.R.S., of St. George's Hospital, certifies them to be far superior to those made of glass or metal, as they are not liable to break, do not corrode, and for accuracy are not to be equalled; and he strongly recommends them to the medical profession. This recommendation we can, from personal examination, endorse.

## THERAPEUTIC RECORD.

**STRYCHNIA IN ALBUMINURIA.**—Brignoli, in *Lo Sperimentale*, besides recommending nux vomica in various neuroses, gastralgia, dyspepsia, cardiac palpitations, periodic cough, etc., states that he has observed it to have a marked effect in retarding the progress of albuminuria, especially the scarlatinal form with anasarca. He cites twelve cases of complete recovery.

**VOMITING OF PREGNANCY.**—Dr. Hubert, in a memoir read before the Medical Society of Lyons (*Lyon Médical*, 15th Oct. 1871, p. 467), produces evidence to show that in some cases this symptom depends upon displacement and movements of the uterus, and that it may be arrested by the immobilisation of the uterus by suitable bandages and the use of Hodge's or Zwanke's pessary.

**THE BROMOHYDRATES OF QUININE AND CINCHONINE.**—In a communication laid before the Academy of Medicine of Paris on Oct. 17th, 1871, M. Latour recommends these preparations to the attention of physicians. He prepares the neutral bromohydrate of quinine, it is stated, by dissolving the bromide of potassium in a slightly acidulated solution of sulphate of quinine; the basic bromohydrate by treating the neutral sulphate of quinine, dissolved in a mixture of equal parts of water and alcohol, first with a very dilute solution of ammonia, then with a neutral solution of bromohydrate of quinine.

**CHLORAL IN CHOLERA.**—Dr. von Reichard has employed chloral in the recent epidemic of cholera at Riga—first, to calm the cramps at the outset; secondly, to lessen the præcordial anguish in the last stage; thirdly, to arrest the vomiting; fourthly, to induce sleep, for which the patients have earnestly prayed. It has successfully fulfilled all these indications. In one case, in which the patient was in *extremis* and had apparently not three hours to live, sixty grains of chloral gave calm sleep; the temperature rose; the pulse fell from 130 to 90, and regained a certain fullness; the *facies cholericæ* disappeared; and the patient was, as it were, snatched from the jaws of death. Dr. Blumenthal, in three cases of severe cholera, saved two out of three patients. The doses administered were sixty grains in half-an-ounce of water twice or thrice in an hour. (*Berlin Clin. Wochenschrift*; *Gazette Méd. de Strasbourg*, 11th October, 1871.)

THE Subscriptions to the Association for the year 1871 became due in advance on January 1st. All which are not already paid, should be forwarded to the General Secretary, Mr. T. Watkin Williams, 13, New Hall Street, Birmingham; or to the Secretaries of Branches.

## BRITISH MEDICAL JOURNAL.

SATURDAY, OCTOBER 28TH, 1871.

### PROVIDENT DISPENSARIES *VERSUS* BENEFIT-CLUBS.

IN the discussion which has lately taken place upon the medical relief of the poor and the abuse of hospitals, it has been said that benefit-clubs are the "correlatives" of provident dispensaries, and that the medical man does well to fill up the club-certificates, which are frequently brought to him at hospital, notwithstanding the serious inroad which they make upon his time and attention. This is a statement which we cannot allow to pass unnoticed, because we consider that it institutes an unfair comparison between benefit-clubs and provident dispensaries, and because it would impose upon medical men a task which we believe they ought on the contrary invariably to decline.

That benefit-clubs are useful and valuable, as far as they go, we readily admit; but their medical arrangements are so far from satisfactory that we cannot regard them, in their present form, as answering the same end as provident dispensaries. That they might be amended and made useful as a system of insurance against sickness we do not doubt, but as yet they fall far short of meeting the requirements of the industrious poor in this respect. Our present object is to point out to our readers those features which make the provident dispensaries more suitable to the demands of the day.

It is obvious that what is wanted is the means of giving to all poor persons an opportunity of obtaining good medical attendance on terms which they can afford to pay, with as few obstacles and difficulties as possible. If we would rid the hospitals of the abuses which now form a serious drawback to their charitable operations, we must provide the working classes with first-rate medical advice, which shall be open to all comers, and which shall be obtainable on the cheapest terms compatible with security and with the reasonable remuneration of those whose professional services are called into requisition. It is a mistake to suppose that the poor do not appreciate the difference between first-rate and third-rate advice; between a skilled and an unskilled hand. On the contrary, they are quick to apprehend these differences. How often are we told by unsuitable applicants in our out-patient rooms that they have only come to the hospital because they knew that there they would get the best advice? Any system, therefore, which proposes to meet the wants of the industrious poor must not only be open to all, but it must also be such as to recommend itself to our profession, and to secure the services of thoroughly efficient practitioners.

Now, how far do the benefit societies fulfil these conditions? In the first place, they are limited almost exclusively to men; very few indeed make provision for attending the wives and children of members, and yet it is these who most frequently require the services of the medical man. Again, many artisans and labourers are altogether excluded from the highest class of clubs, because the trades at which they work are injurious to health or dangerous to life. Again, if we inquire into their medical arrangements they are equally unsatisfactory. The struggles which have lately been carried on in various parts of the country between clubs anxious to beat down the remuneration of their doctors, and the medical men who were desirous of maintaining their just rights and the dignity of their profession, have been recorded in the pages of this JOURNAL. But this is not the only complaint we have to make against the usual system of the clubs. Not only are they prone to drive

a hard bargain with our professional brethren, but many of them, specially in the metropolis, have no medical man at all attached to them. Though they may have accumulated and funded a large capital, and though their sick payments may amount to several thousand of pounds in the course of a year, yet they have no medical officer whatever in their pay. And why? Simply because through the superabundance of our medical charities they can get the work done for nothing. They can send their members to the nearest hospital or dispensary, and there they receive not only advice and medicine, but their club-certificates are also filled up from week to week; and it is in this way that the warrants are signed upon which thousands of pounds are annually paid out. This is an obvious and gross injustice both to medical men and to public charity. The benefit-club should undoubtedly retain the services of a medical man, and pay him a fee proportioned to the number of its members or to the amount of its annual sick grants; and money which has been given by the public for the relief of the needy ought not to be employed in doing the work of a prosperous society. But the evil does not stop here. The members who are sent to the hospital or dispensary are themselves pauperised by being induced to receive as a charity that which their clubs ought to pay for in the regular way of business out of the members' subscriptions.

Let us now contrast these arrangements with those of the provident dispensaries. These latter institutions are open to all—men, women, young persons, and children—whose earnings do not exceed a certain fixed limit. They reject none because their manner of life is beset with more than ordinary risks. They are managed by committees of gentlemen, of which the medical men are themselves *ex officio* members, so that they are sure of courteous and considerate treatment; while the success which has attended them where they have had a fair field and been efficiently conducted, has enabled them to give their medical officers a reasonable remuneration. Add to this that their moral effect is excellent, for it tends to encourage habits of independence and self-reliance among the members. Thus we see that, both on the side of the working classes and of the medical profession, they offer all that can be fairly demanded.

In considering, therefore, the relative merits of these two agencies for meeting the medical wants of the poor at the present day, we have no hesitation in giving our voice in favour of the provident dispensaries. If the country were well supplied with such institutions, and if they were affiliated to one another, so that the artisan and the factory girl who had once been enrolled a member might find an institution at hand of which they would be considered members wherever personal circumstances or the demand for labour might lead them, we believe that it would be a great boon to the working class, and would advance the best interests of our profession.

THE total number of freshmen at the eleven metropolitan schools registered up to Wednesday last amount to 470, or a total of 1486.

THE Sewage-Irrigation Works at Leamington were formally opened on Monday by the Chairman of the Local Board of Health.

A NEW Lunatic Asylum is to be built in and for the county of Northampton, to accommodate 518 patients.

THE next preliminary examination in Arts for the diplomas of Fellow and Member of the College of Surgeons will be held on the 19th, 20th, and 21st of December, when it is expected the number will be as large as on former occasions.

A new Pharmacopœia for the German Empire is about to be compiled. For this purpose, a committee of twelve members has been appointed, who held their first meeting on September 28th. A grant of 40,000 thalers (about £5,830) has been voted from the public revenue for 1872.

A **SPLENDID** testimonial, including a carriage and pair and handsome pieces of plate of the value of £600, has been presented to Mr. Cordy Burrows of Brighton—an old and esteemed member of the Association—by his fellow townsmen.

THE death of Sir Roderick Impey Murchison, Bart., has caused another vacancy in the required number of Trustees of the Museum of the College of Surgeons. This vacancy, with that caused by the death of Mr. George Grote, will be filled up at an early meeting.

#### THE AMERICAN GOVERNMENT AND THE LADY-DOCTORS.

IT appears that the ladies in America are receiving practical recognition of an official character. The State Board of Health in Massachusetts, with the view of investigating the effects produced on the health of women by the use of the sewing-machine, has selected Dr. Lucy Sewall of Boston to prepare a report on the subject.

#### THE OFFICIAL TRIALS OF CONDURANGO.

IT will be remembered that the American Government forwarded to the Government of this country a quantity of the Condurango plant, in order that its alleged influence over cancer might be tested. In some of the State hospitals of America it had been already given to some extent, but with purely negative results. The London College of Physicians was requested by our Government to report on its therapeutic influence, and accordingly forwarded the supply of the drug to the Middlesex and St. Bartholomew's Hospitals. It will be seen from the detailed reports, for which we are indebted to Dr. John Davidson, that so far condurango has failed to arrest in any degree the progress of the disease in those cases in which it has been up to this time tried in the Middlesex Hospital.

#### HER MAJESTY'S HEALTH.

A STATEMENT has been persistently circulated and placarded by a certain class of agitators, that the recent illness of the Queen has been due to her revaccination in the early part of the year. But for the fact that it has reached circles which should be better informed, we should think it unnecessary to notice this absurd misstatement. We are, however, able to contradict it upon the highest authority. It may, under present circumstances, be useful to state that it is entirely without foundation.

#### INTERNATIONAL COPYRIGHT.

MEDICAL authors are, perhaps, more affected by the question of American copyright than any others, as a class; for there are very few British medical works of repute which are not reproduced on the other side of the Atlantic, and their sale there is very large. There is one step which would, we think, offer a generous and effective solution of the question—to pass a law protecting American copyrights in this country. No reproductions of American medical works have, so far as we are aware, been made, in this country, except on a small scale, and by the inferior class of publishers. At any rate, we have clearly no right to pirate American books under any circumstances. The passage of such an Act, without waiting for a *quid pro quo*, would be the best way to prove the strength of our own convictions; and we believe that American legislators would not choose to stand alone in the path of iniquity.

#### AN ENGLISH PHYSICIAN BEFORE A FRENCH COURT-MARTIAL.

DR. ROSE CORMACK gave evidence on Monday last before a court-martial at Versailles, in the case of Saint-Bris, a Communist mentioned in Dr. John Murray's account of his visit to the Ambulance Anglaise in May, which appeared in the JOURNAL of June 10th. The accused wished to prove that he had never actually fought against the army of Versailles; and, as the company of National Guards to which he belonged had attacked the Government troops on the very day (May 11th) on which he was wounded, it was very important to establish that the wound occurred accidentally and some hours before the battle. He proved that, an hour after the accident, the statement he gave to Dr. Cormack was this: "Mon revolver est tombé et le choc a fait partir le

coup." Dr. Cormack's evidence showed that the wound was not inflicted by a Chassepot bullet; and his description of it entirely corroborated the statement of the accused, who was consequently acquitted of the charge of having been engaged in the combat of May 11th. Another count in the indictment was, however, substantiated, and the complete and hearty complicity of Saint-Bris in the insurrection was clearly proved. He was sentenced to transportation for life to New Caledonia. The giving evidence before the military tribunals now sitting at Versailles is not a pecuniarily profitable occupation. Witnesses are only allowed at the rate of five francs a day as a compensation for time given and to reimburse the cost of travelling. For three days' attendance on the court-martials of last week, Dr. Cormack consequently received fifteen francs. The summons obliges attendance under heavy penalties.

#### RUGBY AND CHARTERHOUSE.

THE Senate of the University of London yesterday exercised for the first time its privilege, under the Public Schools Act, of appointing a member of the governing body of Rugby and Charterhouse Schools. To Charterhouse it appointed Mr. Busk, F.R.S., President of the Royal College of Surgeons, thus recognising the claims of science in the direction of education. To Rugby it nominated Dr. Temple, Bishop of Exeter, an appointment which, under existing peculiar circumstances at that school, is likely to occasion a good deal of remark.

#### FATAL MARCHES.

THE *Militär Wochenblatt* discusses at length the precautions necessary to prevent the fatal accidents which occur among troops making forced marches during hot weather. First, of course, is the regulation of the march. This should take place during the earlier hours of the morning, the men resting at midday, and marching again in the afternoon. The soldiers should breakfast before starting in the morning, and should be made to understand the danger of drinking spirits on an empty stomach. The water-bottles should be filled with water slightly acidulated, or with weak tea, which is better. The sale of gin by the cantineers should be prohibited; and the sale of beer should be opposed by attaching water-carts to the columns. The columns should be elongated as much as possible; and, in passing near water, the men should be allowed to stop to fill their bottles. The bottles should have narrow drinking-spouts, so as to force the men to drink slowly. The upper buttons of the collar and tunic should be opened; and the surgeons ought to be mounted, so that, after staying to give timely aid to men compelled to fall out, they may as quickly as possible rejoin their detachments.

#### A SAD LESSON.

OUR obituary list includes to-day a death which deserves public attention. Mr. Faithorn had been in practice in Chesham for nearly thirty-five years. For years he was the only medical man there; but two years ago he took a partner (Mr. Churchill) much his junior. This town has been allowed, in spite of Mr. Faithorn's repeated and urgent protestations and threats of appeal to the central authorities, to fall into a horrible state of dirt and neglect of ventilation, drainage, etc. Somewhat more than a month since, two tramps went down in search of work, and took lodgings in, of course, one of the lowest parts of the town. They both shortly afterwards sickened of typhus, and one was removed to the poorhouse of the neighbouring town of Amersham. From the other, who was nursed at Chesham, the fever spread to all the lowest parts of the town—concentrating itself, however, in one low and dirty locality; and there it continues still to prevail. Mr. Faithorn's partner soon took it, and for some time was in the greatest danger, but is now recovering. Now arose the danger for Mr. Faithorn, who worked alone day and night in the most extraordinary manner, even after the fever had attacked him. At last, he could work no longer; and twelve days afterwards he died, at the age of 64. He had so exerted himself amongst the fever-patients, hardly giving himself rest night or day, and acting even as nurse as well as doctor, as was his habit where necessary, that it

is no wonder that he succumbed to the disease. Besides the two medical men, no one well fed and well lodged has up to this time taken the fever. These, we believe, are the accurate circumstances under which this faithful soldier met his death. They afford a striking instance of the gross neglect of all the rules of common sense, by which many of our country towns and villages, which, like Chesham, are situated in the most beautiful parts of England, and ought to be models of everything healthy, are turned into fever-dens. We cannot but feel strongly on this occasion; for it is to this disgraceful neglect of the proper rules of health and decency that his profession, his patients, and those still nearer to him, owe the loss of a man of eminent worth. He was a man of never failing courage and energy, of a kindness and warmth of heart beyond the common, and as unselfish as he was devoted.

#### VACCINATION PROSECUTIONS.

AT the Manchester City Police Court, Henry J. Jones was summoned for having neglected to take or send his child to the public vaccinator to be inspected after vaccination; but the magistrate decided that the prosecutor was bound to prove that the child had not been vaccinated, and, as he was not prepared to do so, the summons was dismissed.—At the Hartlepool Petty Session, Thomas Martens, a news-agent, was charged with having neglected to pay a fine and costs imposed in May last, to which he pleaded poverty and consequent inability to pay. A distress warrant was issued for the recovery of the amount.

#### CURIOSITIES OF LIFE.

THE *Philadelphia Medical Times* gives the following as interesting to many readers. Half of all who live die before seventeen. Only one person in ten thousand lives to be one hundred years old, and but one in a hundred reaches sixty. The married live longer than the single; and out of every thousand born only ninety-five weddings take place. Of a thousand persons who have reached seventy, there are of clergymen, orators, and public speakers, forty-three; farmers, forty; workmen, thirty-three; soldiers, thirty-two; lawyers, twenty-nine; professors, twenty-seven; doctors, twenty-four. Farmers and workmen do not arrive at good old age as often as clergymen and others who perform no manual labour; but this is owing to the neglect of the laws of health, inattention to proper habits of life in eating, drinking, sleeping, dress, and the proper care of themselves after the work of the day is done. These farmers or workmen eat a heavy supper on a summer's day, and sit around the doors in their shirt-sleeves, and, in their tired condition and weakened circulation, are easily chilled, laying the foundation for diarrhoea, bilious colic, pneumonia, or consumption.

#### CHOLERA.

THE last advices from the East are to the effect that cholera is spreading in Constantinople, it having assumed an epidemic form at Kassim Pasha, a filthy locality on the edge of a drain emitting an abominable stench. The deaths from September 26th to October 1st are stated to have been 136. Steps are being taken, however, to arrest the disease; for a committee has been appointed for rendering assistance in the shape of medical aid, etc.; and temporary accommodation is to be provided in different parts of the city for the reception of the sick on land, and two floating hospitals are to be provided for cases which may arise amongst the shipping; and a system of house-to-house visitation is to be organised. A sanitary cordon is established round Kassim Pasha. A cleansing out of some of the most crowded parts of the place is being made. Food and medical aid are afforded to those who are in want of such assistance. Cholera is now assuming a sporadic form in Dantzig. The deaths from August 1st to October 4th were 46; the cases 60, of which 14 are said to have recovered.—In Elbing, 107 deaths are reported to have occurred from cholera between August 1st and October 4th.—In Königsberg, the latest cholera statistics are for the days October 7th to 10th, both inclusive, during which time there were 2 cases and 2 deaths. The deaths from all causes in the week ending October 15th were 82.—Further particulars of the cholera in St. Petersburg show that the epidemic has very much decreased in

that city. The numbers were, for the week ending September 27th, 20 cases, 27 recoveries, 12 deaths; for the week ending October 4th, 8 cases, 14 recoveries, 2 deaths. The number of cases under treatment on October 5th was 20.

#### MR. CHRISTOPHER HEATH ON CIRCULATION.

WE have before us a correspondence relating to matters of some importance to the interests of members of the Association and of their JOURNAL, and of so essentially a public character, that we feel bound to refer to it. The parties to it are Mr. Christopher Heath and the publisher of the JOURNAL. It is somewhat long, and includes various repetitions, but the substance may be pretty briefly stated. Mr. Christopher Heath opens the correspondence by a formal communication, advertising to the statements on one of the advertisement circulars. They are as follows.

"The following extracts from the last four years of the Government Newspaper Stamp Returns illustrate the leading character of the circulation of the BRITISH MEDICAL JOURNAL, and its rapid and continuous increase.

	1867.	1868.	1869.	1870.
The BRITISH MEDICAL JOURNAL . . .	121,400 ..	163,000 ..	171,700 ..	193,750 ..
The Lancet . . . . .	90,575 ..	99,250 ..	87,500 ..	93,025 ..

And in another place:

"Allow me to call your attention to the BRITISH MEDICAL JOURNAL, which is now by far the most widely circulated of medical journals."

This, Mr. Heath states, is "misleading," and "carries a palpable misstatement on the face of it; for, whatever the number of stamps issued to the BRITISH MEDICAL JOURNAL and *Lancet* respectively, the circulation of the latter is very much larger than that of the former." He further believes that from the stated number of members five hundred defaulters would have to be deducted on June 30th. He declares, therefore, the statements of the circular in this respect to be "fallacious, dishonest, and dishonourable to the Association." To this astounding communication the publisher replies by expressing regret at the character of the language which Mr. Christopher Heath thinks fit to employ. The figures quoted, he observes, are the official and vouched figures of the Government Stamp Returns. They show precisely what they assume to show: that the BRITISH MEDICAL JOURNAL circulates nearly two thousand more stamped copies a week than the *Lancet*; and that it has nearly doubled its stamped circulation in the last five years, while the *Lancet* has stood still, with occasional periods of retrogression; and to this extent the figures afford an index to the character of the total circulation. The number of stamps used in 1871 for our JOURNAL is over 210,000. Our publisher adds that his statement as to the excess of the total circulation of the BRITISH MEDICAL JOURNAL over the total circulation of the *Lancet* is equally explicit, and is not made at random. He differs entirely from the opinion which Mr. Christopher Heath expresses; and, that the matter may be settled on a basis of facts, he invites Mr. Heath, as a representative of the *Lancet*, to submit to the publishers of that paper his challenge to place the books of both journals in the hands of a respectable accountant, and to publish the attested numbers. The deduction of five hundred members on June 30th, which Mr. Heath thinks should be made, he points out to be an error. So many had paid up arrears, and so many new members had been elected before that time, that from June 30th it became necessary, on the contrary, to print two hundred and fifty more copies of the JOURNAL weekly than in the preceding quarter. Mr. Heath, in reply, considers it "impertinent" that he should be addressed as a representative of the *Lancet*. He states that he writes in his new character of member of the Committee of Council, and asks on what ground he is identified as a representative of that journal. The publisher replies that he so addresses him because his recent communications to the office in the month of August were in the official character of representative of the *Lancet*, asking for early copies of documents relating to the Plymouth meeting, as *Lancet* reporter at that meeting, which were furnished by direction of the editor; and that his recent letter advocated the interests of that

journal in somewhat passionate language, and implied a precise knowledge of its affairs. He renews his challenge. Mr. Heath replies that he wrote his letter in his own study, without consulting the proprietors of the *Lancet*; and that "he does not know the circulation of that journal!" To this utterly surprising anticlimax the publisher replies by asking that Mr. Christopher Heath shall either justify or retract his injurious imputations. To this Mr. Heath has as yet made no reply. He can hardly, however, refuse to respond to this just claim, for the sake of his own credit, whether in his character of a spokesman representative of editorial staff of the *Lancet*, or in that other character of a guardian of the interests of the British Medical Association and its JOURNAL, which he somewhat anomalously accepted in becoming a member of the Committee of Council. The challenge of the publisher of the BRITISH MEDICAL JOURNAL (thus provoked by Mr. Heath), that the books of the two journals shall be compared by a public accountant, in order publicly to verify the statement as to the superior circulation of the BRITISH MEDICAL JOURNAL, on which Mr. Heath throws doubt, remains open.

#### DR. RICHARDSON'S LECTURES ON EXPERIMENTAL AND PRACTICAL MEDICINE.

THE first lecture of Dr. Richardson's eighth course on Experimental and Practical Medicine, will be delivered at 12, Hinde Street, next Tuesday, October 31st. The course will be continued on the last Tuesday of every succeeding month until March. The present series will commence with a lecture on "The Science and Art of Embalming the Dead."

#### DR. HITCHMAN OF THE DERBYSHIRE ASYLUM.

DR. HITCHMAN, whose instructive paper on Paresis of the Insane, read before a recent meeting of the Midland Branch of the British Medical Association, we print to-day, has lately resigned the office of Medical Superintendent of the Derby County Asylum, which he has held for twenty-one years. At a meeting of quarter sessions last week, it was resolved, without one dissentient voice, to grant to Dr. Hitchman a superannuation pension of £400, and one of £100 to Mrs. Hitchman. Dr. Hitchman took an important part in the original organisation of the asylum, and during his term of office he has brought to its management and to the treatment of its inmates rare qualities of skill, judgment, and character, which have conciliated for him the respect and esteem of those among whom he has lived, not less than of the members of his profession.

#### THE SANITARY SHAME OF LIVERPOOL.

RELAPSING fever has reappeared in Liverpool. A mortality of three is this week recorded from this cause. This would probably imply the existence in the town of some two or three hundred cases. We have already referred to the subject of the deplorable habits, unfortunate sanitary condition, and high mortality, which afflict and disgrace the poorer classes in Liverpool. We have received a communication from Dr. Skinner on the subject. We are prevented by want of space from dealing with it this week; but we hope to be able very shortly to print Dr. Skinner's letter and discuss its theme.

#### SMALL-POX IN WOLVERHAMPTON.

OUR readers will certainly not be surprised to learn, after what we wrote last week, that small-pox is rife in Wolverhampton. There are about two hundred cases in the borough, and the number is increasing. The epidemic has broken out in the Police Barracks, from which one officer was removed to die in the fever-hospital in the workhouse. The barracks have been abandoned for the new ones elsewhere, and the old barracks extemporised into a small-pox hospital for Wolverhampton. The Poor-law Guardians have represented to the Corporation the great danger resulting from the spread of small-pox. The death-rate is thirty-three in the thousand, and application is about to be made to the Home-Office to interfere and compel prompt action by the local authorities.

#### FLEXIBLE PROBES.

WE referred recently to the excellent flexible probe, which Mr. Steele of Bristol introduced to the profession here simultaneously with, but independently of, that of Dr. Sayre. Dr. Sayre writes from New York to express his opinion that this probe is "in some respects better than his own for certain cases, and it is much more easily cleaned. Both of them are necessary." He expresses a warm sense of pleasure at the cordial and gratifying reception which he had at the hands of his professional brethren in England.

#### PAWNING INFECTED CLOTHES.

LAST week, at the Salford Town Hall, a woman named Elizabeth Griffiths was summoned for having committed a breach of the Sanitary Act, 1866, by exposing a shirt which had been worn by one of her boys (now dead), who had been suffering from small-pox, without having had the shirt previously disinfected. The prisoner, who has living another child infected with small-pox, pawned the shirt, for which she was committed to prison for a month. The sick child was sent to the workhouse.

#### THE MEDICAL SOCIETY OF LONDON.

IN opening the ninety-ninth session of the Medical Society of London on the 16th instant, the President, Dr. Andrew Clark, congratulated the Fellows on the prosperity of the Society. As regarded financial matters, the Treasurer had a balance of £211; the Fothergillian fund had risen to nearly £1,000; and it was expected that the Society's house in Bolt Court, bequeathed by Dr. Lettsom, would soon be let at a much improved rent. The prosperity of the Society was to be kept up by aiming at precision in work, which should be compendious and practical; and by working with singleness of heart and purpose, in the spirit of good fellowship. As an instance of the value of the labours of such a Society, he referred to the investigation of the early history of disease, such as phthisis. In therapeutics also—regarding which there was a want of faith, and also a want of precise knowledge—important investigations might be made by committees of the Society, aided by grants from the surplus Fothergillian funds. Each Fellow should induce other members of the profession to join. It was in such a Society that fresh knowledge was obtained, errors were corrected, and doubts resolved. The President concluded by alluding to the great loss which the Society had sustained in the death of Dr. Hyde Salter, who at one time had been three years its Secretary. He had accepted the Lettsomian lectureship, but, finding his health failing, resigned the appointment early in the year.

#### OUT-PATIENTS AT HOSPITALS.

THE number of new cases in the out-patients' department of the metropolitan general hospitals relieved during the week ending Saturday, October 14th, according to the *London Mirror*, was 15,627—the highest at any one hospital being 2,811 at the London Hospital. The numbers at the several hospitals were: Charing Cross, 249; Great Northern, 535; Guy's, 2,400; King's College, 1,490; London, 2,811; Metropolitan Free, 622; Middlesex, 1,300; Royal Free, 897; St. Bartholomew's, 2,467; St. George's, 340; St. Mary's, 387; St. Thomas's, 1,375; University College, 284; and Westminster, 470—total, 15,627.

#### SMALL-POX IN SHEFFIELD.

OUR correspondent writes as follows:—Small-pox is rife in Sheffield; and there is but a single vaccination-prosecutor, although there is abundant work for three. On the 18th inst., a deputation from the Health Committee waited upon the Board of Guardians on the subject of the desirability of erecting a hospital for contagious diseases. At Eccle-shall the guardians are going to build an iron house which will hold, at a cost of £240, twelve beds. It was suggested by the deputation that the Board might adopt a similar course. The chairman suggested that one of the wings of the Union should be extended, and it was ultimately decided that an architect should be asked to prepare

plans of the extension. Sheffield has long felt the want of a hospital for contagious diseases, and it is to be trusted that the guardians will act promptly and liberally in the matter.

#### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THIS society commenced its session on Tuesday evening. Under a new rule passed last session, it was intended to commence the meetings henceforth a month earlier than has hitherto been the case. Extensive alterations, however, having been in progress on the Society's premises, it was necessary to omit the meeting which should have been held on the 10th. The alterations are still incomplete; a large room for meetings, which is being prepared in the rear of the library, hitherto used for this purpose, being not yet ready for use. The attendance of members on Tuesday was rather scanty; not more than about thirty-six being present. The proceedings commenced with the reading of an interesting report, by Mr. Le Gros Clark, of a case of obstruction of the ileum by large gall-stones. After this followed a paper by Mr. Warrington Haward, on ether and chloroform as anæsthetics. From his experience as an administrator of anæsthetics in St. George's Hospital, he was led to advocate the use of ether more extensively than is the case.

#### IMPROVEMENT OF DWELLINGS.

UPON this subject the following resolution was moved in the Economic Section of the Social Science Congress by Mr. John Holmes of Leeds, seconded by the Rev. H. Solly, and carried: "That the Section recommends the Council to take into its consideration what legislation can be taken to improve and render more effective the Public Health Acts, giving power to close or remove property found unfit for habitation; and, further, by what means statistical information could be obtained as to the experience of the various companies, societies, or other organisations, which are engaged in providing dwellings for the working classes."

### SCOTLAND.

DR. JOHN CHIENE has been appointed Assistant-Surgeon to the Edinburgh Royal Infirmary.

MR. WILLIAM WALKER has been elected President of the Royal College of Surgeons of Edinburgh.

DR. GILLESPIE, after completing twenty-one years' good service on the surgical staff of the Edinburgh Royal Infirmary, has been appointed Consulting Surgeon.

THE sum of £3,470 has been subscribed towards £5,000 which is required for the new buildings of the Glasgow Convalescent Home at Lenzie Junction.

#### THE LADY-STUDENTS IN EDINBURGH.

THE Senatus and University Court will not oppose the admission of the lady-students to the professional examination. Technical difficulties have been raised, but have been overruled by legal advice. The whole question is, however, not yet resolved, and the ladies are determined to carry on the war till they win the coveted medical degree.

#### THE SALE OF THE EDINBURGH ROYAL INFIRMARY TO THE UNIVERSITY.

A FINAL interlocutor in both of the cases of suspension and interdict against the managers of the Royal Infirmary in respect of the contemplated sale of the Infirmary buildings to the University was issued by Lord Gifford on Tuesday. The former notes of suspension and interdict have been confirmed and declared perpetual by his lordship.

#### FEVER IN DUNDEE.

It is stated in the Dundee papers that the overcrowding of fever-patients in the Infirmary of that town is on the increase, and that in some cases two patients have to be placed in the same bed. It is difficult to imagine how this can be. The great and increasing prevalence of fever

in the town has been a matter of public notoriety for some time, and the authorities have had more than abundant time to afford a larger increase of accommodation than is now required. The Metropolitan Asylums Board were enabled to erect one of the most complete hospitals in London, capable of containing one hundred and fifty beds in a month. There can, therefore, be little excuse for the authorities in Dundee allowing the present state of matters to continue.

#### A NEW SCOTCH ACIDULOUS CHALYBEATE WATER.

DR. JAMES DEWAR, F.R.S.E., describes in the *Chemical News* a remarkable chalybeate water. Plenty natural waters, containing small proportions of iron, are to be met with in the United Kingdom; but, with the exception of those of Tunbridge Wells, Harrogate, Sandrock (Isle of Wight), Heartfell (near Moffat), and Vicarsbridge, in the vicinity of Dollar, they contrast very unfavourably with those of the numerous spas of the continent of Europe. If we restrict ourselves to an examination of the chemical characters of the above-mentioned Scotch chalybeates, we observe that the iron is present in large quantities in the form of sulphate, along with sulphate of alumina, on which account they are more nauseous to invalids, and are at the present time rather unpopular. Recently Dr. A. Dewar of Melrose sent to him for analysis a sample of a new well-water, whose peculiarity had previously attracted his attention. A chemical examination of the water in question showed it to be a well-defined acidulous chalybeate, unusually rich in carbonate of iron. The following are the analytical details. (As the surface-water gets access at present, a very exhaustive analysis appeared unnecessary):—Carbonate of iron, 17.5 grains per gallon; alumina, 1.8; silica, 8.5; sulphate of magnesia, 7.8; chloride of calcium, 16.0; carbonate of calcium, 4.1; alkaline chlorides, 11.4—total, 67.1. Carbonic acid gas per gallon, 40 cubic inches.—With the exception of the celebrated "Dr. Muspratt's chalybeate", at Harrogate, which contains 10.8 grains per gallon of carbonate of iron, along with 16.0 grains of protochloride, he does not know of any natural water in this country containing such a large proportion of iron in the form of carbonate. And it is to be observed that the water is not associated with a large quantity of other salts. The well whence the foregoing sample was taken has not been long sunk, and its water is perfectly different from all of those in its immediate vicinity. Should it maintain its present character, he has no doubt that, judging from its own qualities, as well as from its favourable climatic situation, along with the general interest attached to the locality, this chalybeate is certain to recommend itself to the medical profession.

### IRELAND.

#### MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS IN IRELAND.

THE General Annual Meeting of the Association for the election of Council and Secretary for the session 1871-72 was held on the evening of Wednesday, the 18th of October, in the College Hall. The following were elected members of Council:—Lombe Atthill, M.D., John T. Banks, M.D., Thomas Fitzpatrick, M.D., Samuel Gordon, M.B., T. W. Grimshaw, M.D., Thomas Hayden, F.R.C.S.P., George Johnston, M.D., Henry Kennedy, M.B., Robert Law, M.D., James Little, M.D., William Moore, M.D., and Alfred H. McClintock, M.D.; *Honorary Secretary*, Henry Eames, M.D.

#### KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

ON St. Luke's Day, the 18th of October, the annual stated meeting of the College was held, when the following officers were appointed for the year 1871-72:—*President*, Alfred Hudson, M.D.; *Censor*, Samuel Gordon, M.B.; *Vice-Presidents*, John Ringland, M.D., James Little, M.D., T. W. Grimshaw, M.D.; *Treasurer*, Henry Dwyer, M.D.; *Registrar*, J. M. Finay, M.B.; *Representative on the General Medical Council*, Aquilla Smith, M.D.; *Professor of Medical Jurisprudence*, Robert Travers, A.M., M.D.; *Examiners in Midwifery*, G. Johnston, M.D., and Lombe Atthill, M.D.

## THE MEDICAL CHARITIES OF IRELAND UNDER THE POOR-LAW.

### I.—THE DISPENSARY SYSTEM.

ALMOST every important enactment in connection with the Poor-law, from the earliest period of its history, has been obtained from a Legislature intimidated into action through the devastations of fever and famine. The passing of the Medical Charities Act (Ireland) in 1851 was consequent on, and necessitated by, a period of pestilence and famine, from which Ireland was just emerging. An impartial observer, writing of that period, says, "In the early months of 1849 there were greater privation and suffering among the population of the western and south-western districts than at any time since the fatal season 1846-47. The cabins were crowded with ill-fed, ill-clothed, sickly people; and epidemic disease found victims prepared for its attacks; and in March cholera broke out in these unions, whence it afterwards extended to other parts of the country. Such was the state of affairs in Ireland in 1849; and it now became manifest that the voluntary dispensary system of medical relief was partial and insufficient. In August 1851, therefore, this Bill was introduced and readily passed."

The advantages that have accrued to the country under the working of this Act, the admirable way in which it has been administered by the Poor-law Commissioners, and the efficient manner in which its objects have been carried out by the dispensary medical officers, have so frequently been referred to in these pages, that it is almost a work of supererogation again to mention them. The dispensary system has been at once productive of improvement in the health of the people, and of the most economic results to the ratepayers, thus proving the relationship that exists between sickness and pauperism. This is further substantiated by the fact that, at present, there are not enough able-bodied persons in the workhouses in Ireland to do the household work of those institutions. It would appear that there are but 4.9 per cent. of able-bodied males and 11 per cent. of able-bodied females in receipt of in-door relief; and only 53,885 persons received out-door relief during the year ending September 29th, 1870. The total number of persons admitted into the Irish workhouses during the same year was 183,135. Of this number, 49,749 were admitted on account of sickness; of these, 8153 were suffering from fever or other contagious diseases, 39,086 from "other diseases", and 2510 from accidental injuries. This does not include the City of Dublin, which furnishes as many cases of fever as are admitted into all the workhouses in the other parts of Ireland together. Neither of the two Dublin workhouses admits zymotic disease of any kind. The dispensary medical officers of Ireland also during the same period attended 784,424 cases of disease; 203,200 of the patients were visited at their own homes. Amongst other cases, they had 7424 cases of scarlatina, 51 cases of small-pox, and 15,744 of fever. They vaccinated 140,220 children. (The workhouse medical officers, in addition, vaccinated 2160, a duty imposed upon them, for which they are not paid.) The dispensary medical officers also certified for 900 dangerous lunatics: this duty is imposed upon them by Act of Parliament, "without fee or reward". They attended 332 patients in the various Bridewells—also without remuneration.

The medicines and medical and surgical appliances are supplied by the guardians: the cost for the year was £23,706:15:10. The rent of the dispensary buildings, 1055 in number, was £7352:10:4; books, forms, stationery, printing, cost £2693:16:3; fuel, attendance, midwives' salary, and incidental expenses, amounted to £8763:6:1. These items, along with the salaries of 800 medical officers (£77,917:8:10) and 41 apothecaries (£2362:0:7), in addition to the fees for vaccination, amount to £129,936:0:8, as the expenditure under the Medical Charities Act (Ireland). Thus it may be considered to be conclusively shown that, for a comparatively small outlay, the Irish dispensary system has proved itself to be a great success for the treatment of disease.

There is one very important subject in connection with the Irish Poor-law Medical Service, which, up to the present time, has not received the attention which it merits. I have already said that it is admirably carried out as a curative system; but the deficiency exists in its preventive agency. Ireland is carefully mapped out and subdivided into dispensary districts, which ought to facilitate improvement in its sanitary condition. The dispensary medical officers annually attend more than one-sixth of the inhabitants. They are the first to come into contact with zymotic disease. They are in constant communication

with the poorest classes, by whom hygiene is most neglected and amongst whom, in consequence, zymotic disease is almost invariably present, and from whom it spreads to the upper classes. It was evidently contemplated under the Sanitary Act of 1866 that the dispensary medical officers should be the health-officers of their respective districts, and provision was made in that Act for the payment for extra medical services performed under its provisions. Yet the Poor-law medical officers are not so employed, except perhaps in rare instances; and then they are not paid for their work. Sanitary work is very imperfectly carried out in Ireland. Of this, the report on the "Sanitary Condition of Dublin", which lately appeared in these columns, furnishes an illustration. Sanitarians of such eminence as Dr. Mapother and Dr. Cameron must know well that the facts stated by Dr. Grimshaw and myself are incontrovertible.

To carry out sanitary law in Ireland efficiently the Poor-law medical officers must be *ex officio* officers of health; and, in order that they may be enabled to do their work fearlessly, they must be independent of local boards. They will not, nor can they be expected, to fall foul of the Union magnate, whose tenement-houses require to be drained or whose village pump requires to be repaired; and much less will they excite the ire of a Mayor and Corporation or a Board of Town Commissioners, more especially when their election and payment, and all their hopes of an increase of salary and superannuation, are centred in those authorities.

The only branch of preventive medicine that is thoroughly carried out in Ireland is vaccination; and this resulted in the stamping out of small-pox in 1869. The total births registered in Ireland ending September 30th, 1870, were 149,244; that is, an annual rate of 28 per 1000 of the population. The vaccinations performed by the dispensary medical officers for the same period were 140,220, by the workhouse medical officers 2160; making a total of 142,380, leaving but 6854 unvaccinated under the dispensary system. That is, of course, too small a number to leave for deaths before vaccination and for children vaccinated by other practitioners, and may be accounted for in this way, that some of the reported vaccinations were re-vaccinations, and that a considerable number of children born were not registered. The birth-rate in Ireland has been stated to be nearer 30 per 1000 than 28. If this be so, the other 2 per 1000 would give an addition of 10,000 children to the total births. It is satisfactory to see, therefore, that both the registration and vaccination are improving; and if 30 per 1000 be correct, deducting still-births (which, until they are registered, will always render the birth-rate incorrect), there cannot on an average in each of the 800 districts be more than six or eight children whom the dispensary medical officers fail to vaccinate. This year there has been a considerable increase of small-pox; but in all the cases traced it has been proved to have been imported, and it spread chiefly either among adults that had not been vaccinated at all, or in whom the work was doubtful, or on those in whom the prophylactic power of vaccination had died out. According to the Medical Charities Act, the medical officer "shall, and he is hereby required to, vaccinate all persons who shall come to him for that purpose". Under another Act the dispensary medical officer is entitled to the sum of one shilling for each case of successful vaccination. In England the minimum fee is one shilling and sixpence; but there is no uniform standard,—one parish may pay two shillings and sixpence for each case of successful vaccination, and the adjoining parish only pay one shilling and sixpence. Where vaccination is performed beyond a given distance from the vaccine station, there is a graduated increase of fee allowed.

There are several curiosities in the vaccination system in England, which are not to be discovered in Ireland. There is a staff of vaccination-inspectors; and there is a system of gratuities over and above the fees paid for vaccination. The regulations which govern the dispensation of these gratuities are far from satisfactory. The quantity per cent. fixed by the authorities is entirely beyond the vaccinator's control; the quality of the vaccination, and the strict observance of the regulations, which involves an immense amount of clerical labour, are the only two conditions which can be controlled and fulfilled by the public vaccinator. According to Mr. Simon's report, the amount distributed under the head of vaccination gratuities in England, amounted to £5685:8 over and above the amount paid for vaccination fees; while the payment for the vaccination of the whole of Ireland was but £6314:4:7. Are not inspectors of vaccination required in Ireland and Scotland as well as England? If gratuities are to be awarded and a large measure of success obtained thereby in England, why not in Scotland and Ireland? Has the expensive machinery with its inspectors, gratuities, vaccination clerks, and the consolidation of large areas and enormous populations into the hands of one vaccinator, separated from the Poor-law Service, protected us from small-pox? It would afford the guardians of Ireland a wholesome lesson, if they would study

the vaccination arrangements in England; viz., the cost and the result. They would surely, then, cease to cry out about the expense of vaccination in Ireland. At one time, they say, the dispensary medical officers vaccinate too many; or they object to pay for re-vaccination, or delay the payment for the vaccinations on the most frivolous grounds. The Commissioners have been necessitated to issue an order that payment should be made in twenty-eight days after the vaccination account is laid before them. This order is not always obeyed; and three months have been allowed to elapse before the account has been paid. As a justification of this delay, the medical officers have been accused of having falsified their returns.

Though the Act requires the dispensary medical officers to vaccinate all who present themselves, yet they are only paid a shilling for each case of successful vaccination of those who reside in their own particular districts; hence, it appears on a careful examination that they only receive a little over tennence for each case. The State gets gratis the protection of those vaccinated out of their districts. There is not that encouragement given to vaccination which is desirable, and it is adduced as an instance of the narrow-minded views which obtain with regard to preventive medicine; but, notwithstanding this, vaccination has become universal in Ireland. Should an improved system of sanitation be adopted in Ireland, and the Poor-law medical officers be enabled to perform the duties connected with public health fearlessly and independently, zymotic disease would greatly diminish; and perhaps it may yet be said of fever, as it has been said of small-pox, "In Ireland it has been stamped out." It is well to remember that in the year 1838 small-pox caused no fewer than 7150 deaths in Ireland, representing, according to the Irish Census Report of 1841, from 40,000 to 50,000 persons attacked with small-pox in that year alone. In the decade ending 1841, there were 58,006 deaths from small-pox; and in the decade ending 1861, when the Medical Charities Act had been but ten years in operation, the deaths from small-pox had diminished to 12,727.

The secret of the success of vaccination in Ireland is doubtless due to the system, which consolidates in one person the offices of registrar of births and deaths, vaccinator, and Poor-law officer, thus affording the greatest facility for carrying out systematic vaccination. To this, now, is required the addition of the function of health-officer in order to establish an unequalled and almost perfect system of State medical relief. The sanitary powers require to be co-ordinated under a health department. The appointment of a health Commissioner for each province, as has been already suggested, with power to enforce necessary sanitary arrangements, and to whom the dispensary medical officers should report from time to time on the state of their districts, would probably be found to be practically efficient. Nor would the duties on the medical officer be very onerous; for, when he was called to attend fever or other zymotic disease, a few pertinent inquiries, a sharp glance round the house and its belongings, would tell him why such a case was there. In a short time the truth will enter even the dullest parochial brain—that if you remove the cause you prevent the fever.

BENSON BAKER,

*District Medical Officer, Christchurch, Marylebone.*

### PROVIDENT DISPENSARIES.

THE following rules have been suggested by the Medical Subcommittee of the Charity Organisation Society for the Establishment and Management of Provident Dispensaries.\*

I. Name of Institution and the boundaries of the district.

II. OBJECT AND DESIGN.—The object and design of the Dispensary is to enable the working classes and such other persons in the district as are unable to pay for medical attendance at the usual charges (provided they are not in receipt of parochial relief), to secure for themselves and their families the advantage of medical attendance, advice, and medicine during illness by their own periodical payments, assisted by contributions from friends of the Institution.

III. THE FUNDS.—There shall be two distinct funds to be called the "Honorary Subscribers' Fund" and the "Members' Fund" respectively. The *Honorary Subscribers' Fund* shall consist of the contributions of friends of the Institution, who shall be called "Honorary Subscribers." The *Members' Fund* shall consist of the periodical and other payments (except those for confinement) made by persons entitled to the benefits of the dispensary, who shall be called "members." The *Honorary Subscribers' Fund*, with the addition of ten per cent. of the

Members' Fund, shall defray the expenses of management, drugs, and medical appliances, and shall supplement the midwifery fees paid by members. (Rule VIII, 4.) The Members' Fund, after deducting ten per cent., shall be paid to the medical officers, in the proportions mentioned in Rule VIII, 4.

IV. HONORARY SUBSCRIBERS.—The Honorary Subscribers shall be the contributors to the Subscribers' Fund of the following amounts:—Five guineas for a Life Subscription, and half a guinea and upwards for an Annual Subscription. The powers are described under the head of "Management," Rule VII.

V. MEMBERS.—The members shall be persons of the working-classes, and others, whose income is proved to the Committee of Management to be insufficient to pay for medical attendance at the usual charges; always provided that the Committee has power to erase the name of a member who is disqualified by improved circumstances. *Note*.—Families earning not more than thirty shillings a week are considered suitable members of London Provident Dispensaries.

1. Any applicant for membership must state his or her name, age, residence, occupation, and average earnings of self and family, and must deposit three months' subscription, which will be returned if the depositor be not accepted a member. If approved of by the Committee, the applicant will be admitted a member at the end of a month; but if the applicant is then actually suffering from illness requiring medical treatment, he or she must pay an entrance fee of five shillings and three months' contributions. And in the event of any other member of the family requiring medical advice before the expiration of the probationary month, each shall pay a further sum amounting to one half of the entrance fee.

2. The scale of payments suggested is as follows:—

	Town, per month.	Country, per month.
A. Adults over 18.....	6d.	4d.
B. Young persons (14 to 18) ...	4d.	4d.
C. Man and wife .....	10d.	8d.
D. Children under 14 .....	2d.	2d.

Any number above four shall not be charged.—*Note*. In order to facilitate the collection of members' payments, it is suggested that cards of four different colours should be issued; so that one-fourth of the members (holding cards of a certain colour) shall come up to pay each week. These sums, when paid, shall be entered on cards to be kept by the members. A man and wife, and their children under 14, shall have one card only.

3. No married man or woman to be admitted unless the whole of the children (if any) join who are under 14 years of age, except in the case of the man when he belongs to some medical club, and produces proof thereof. Children (not orphans) under 5 years of age, cannot be admitted, unless entered with their parent or guardian.

4. Female members of three months' standing may be attended in their confinements on paying at the Institution not less than 15s. in London and large towns, and 10s. 6d. in rural districts, one month previously; or the money may be paid by instalments of not less than 2s. 6d. each, the last of which is to be paid a month previous to confinement. If the attendance of a medical officer is required in a premature confinement by a member, she must pay the full fee of 15s. or 10s. 6d., as the case may be, or any part of it remaining unpaid at the time of sending.

5. Members may have the attendance of the midwife on payment of 5s. The payment must be completed one month before confinement, at one time, or by two instalments; but members of less than three months' standing must pay 7s. 6d.

6. Every member may choose a medical officer from the dispensary staff, but no change can take place during illness without the consent of the Committee of Management.

7. All patients who are able must attend at the dispensary at the appointed times, bringing their cards and prescription papers with them. Children of members will be vaccinated without any charge. Patients must find their own bottles, phials, cups, etc.—*Note*. In some dispensaries it might be desirable to charge for revaccination, to avoid competition with public vaccinators.

8. Patients too ill to attend at the Dispensary must send their cards before nine o'clock in the morning to the residence of the medical officer they have chosen, who will see them at their homes.

9. In cases of sudden illness or accident, members will be attended at any time on sending their cards to one of the medical officers.

10. Notice shall be given by the members to the Honorary Secretary of their withdrawal from the dispensary in consequence of leaving the district; and members who have complied with this rule will be re-admitted on their returning to the neighbourhood without extra payment; but members leaving the district for more than three months without having given notice, will have to pay on their rejoining a fine of 5s. and three months' arrears of contributions.

\* Suggestions for amendment can be sent to Dr. Ford Anderson, 23, Buckland Crescent, Belrose Park, N.W.

11. The payments of members must be made in advance; and no member who is in arrear will be entitled to the benefits of the Institution. Members in arrear must pay fines as follows—2d. for the first month, 4d. for the second month, and 8d. for the third month, in addition to the arrears. Any member in arrear more than three months shall cease to be a member, and shall not be again admitted without the special sanction of the Committee of Management.

12. Members of one year's standing may, on changing their place of abode, be entered on the books of other provident dispensaries, provided they have not been longer than one month in the new district, and provided that such members are not ill at the time.

13. *Powers of Members.*—Adult members of one year's standing shall have a voice in the management of the dispensary. (See Rule VII.)

VI. OFFICERS.—Attached to the dispensary there shall be trustees, a treasurer, a committee of management, an honorary secretary, auditors of accounts, medical officers, a dispenser of medicines, a midwife, and such paid assistants as may be necessary; and all officers shall continue in office till one month after the general meeting, or until their successors are appointed, subject, nevertheless, to the provisions of Rules VII, 2, and VIII, 2.

VII. MANAGEMENT.—The dispensary shall be managed by subscribers of not less than three months', and adult members of not less than one year's, standing. In the case of the members, one claim only for a voice in the management shall be acknowledged for a family card. The powers of the subscribers and adult members shall be exercised only at a general meeting, or at an extraordinary general meeting, in accordance with the object and design of the institution.

1. *General Meetings.*—A general meeting of the working subscribers and adult members entitled to vote (of whom nine shall form a quorum) shall be held annually in the month of — for the following purposes: *a.* To receive the report of the Committee of Management on the transactions and state of the Institution. *b.* To receive the medical officer's report. *c.* To receive the auditor's report of the accounts and state of the books. *d.* To appoint the Committee of Management, Trustees, Treasurer, Honorary Secretary, Auditors of Accounts, and to confirm the appointment of the medical officers for the ensuing twelve months. *e.* To revise, modify, or alter, if need be, the rules of the Institution. *f.* To transact all business relating to the object and design of the Institution.—*Note.* Members entitled to vote must present their cards, in order to avoid recording more than one vote for each card.

2. *Extraordinary General Meetings.*—An extraordinary general meeting of the subscribers and members entitled to vote may be held at any time upon the requisition in writing of nine voters, of whom not less than five shall be subscribers, such requisition to state the object of the meeting, and to be delivered to the Honorary Secretary. Extraordinary general meetings shall have all the authority and powers of, and be subject to the same responsibilities and duties as, general meetings.

3. *Trustees.*—The property of the Institution shall be vested in Trustees [see (1) *d.* of this Rule] for the use and purposes of the Institution, subject to the control, and at the disposal, of the Committee of Management.

4. *Treasurer.*—The Treasurer shall receive all monies paid on account of the Institution, and shall disburse the same on the order of the Committee of Management. He shall keep his accounts according to Rule XII.

5. *Committee of Management.*—The Committee of Management shall consist of not less than nine Honorary Subscribers and adult members entitled to vote; five of these shall be Honorary Subscribers. Three shall form a quorum. The Treasurer, Honorary Secretary, and medical officers shall be *ex officio* members of the Committee. It shall superintend, manage, and conduct the business of the Institution. It shall keep accurate minutes of all its transactions containing cash accounts of receipts and payments. It shall appoint the medical officers, subject to the confirmation of the general meeting or an extraordinary general meeting. It shall have power to appoint and dismiss the dispensers, midwife, and other paid assistants not mentioned by name in Rule XIV. It may also suspend any other officers for neglect of duty, and temporarily appoint another in his stead, and report thereon within ten days to the general meeting or an extraordinary general meeting. In carrying out this clause, action shall be taken by the Committee of Management only when at least two-thirds of its members are present; and it shall report to the general meeting on the transactions, state, and progress of the Institution.

6. *Honorary Secretary.*—The Honorary Secretary shall act under the instructions of the Committee of Management. He shall give eight days' notice in writing to the Honorary Subscribers of any general meeting, and of any extraordinary general meeting, and shall post up a like notice at the dispensary for the same period. He shall receive and pay over to the Treasurer all members' payments, together with all

other monies coming to his hands in behalf of the dispensary; and he shall keep accounts of all such receipts and payments, according to Rule XII.

VIII. MEDICAL OFFICERS.—I. *Number.*—There shall be a Consulting Physician, a Consulting Surgeon, and a Consulting Physician Accoucheur, also medical officers in ordinary; all of whom shall be duly qualified and registered.

2. *Appointment.*—They shall be appointed annually, or when a vacancy occurs, by the Committee of Management, and their names submitted within a fortnight for confirmation to the general meeting, or to an extraordinary general meeting. Canvassing at the appointment of any medical officer is disallowed, and will disqualify for election. *Note.*—The number of medical officers in ordinary to depend on number of members. One for every thousand members suggested as a fair average.

3. *Duties.*—One of the medical officers shall attend daily at the Dispensary at the hours appointed by the Committee of Management; and if a member is prevented from attending by illness, the medical officer selected by that member shall attend at his or her place of abode. They shall attend members (entered under them) in their confinements, who have paid the midwifery fee to the Honorary Secretary; or, in case of premature confinement, members of three months' standing who pay the fee at the time of sending. They shall assist the midwife in cases of difficulty, if she should require them. They shall keep an accurate register of all cases treated by them, and report to the general meeting on the statistics of health of the Institution. They shall inspect and check with their signatures the orders for drugs and the drug bills (see Duties of Dispenser, 1 and 2). No operation of importance shall be undertaken without a consultation with one or more of the Dispensary staff. They shall give three months' notice of leaving.

4. *Remuneration.*—The remuneration of the medical officers shall consist of the Members' Fund (after deducting 10 per cent.) to be divided amongst them half-yearly at Midsummer and Christmas, by the Committee of Management, in proportion to the amount received from the members who have selected them. For every case of confinement which they attend, under Rule V, 4, they shall receive the fee paid by the member, and, in addition, six shillings from the Honorary Subscribers' Fund; and for every case which they attend at the requisition of the midwife (Rule X, 2), they shall receive ten shillings and sixpence from the Honorary Subscribers' Fund.

IX. DISPENSER.—1. *Qualifications, Appointment, Salary, Dismissal.*—A Dispenser, who, if possible, should be a person registered under the Pharmacy Act, shall be appointed by the Committee of Management, at such salary and giving such security as the Committee shall determine, and may be dismissed at its discretion at a special meeting of the Committee called for that purpose, on payment to him of a proportionate amount of his salary.

2. *Duties.*—He shall be present at the Dispensary daily at and for such time as the Committee shall determine. He shall take charge of the drugs and appliances. He shall faithfully compound and dispense medicines to the members of the Dispensary according to the prescriptions of the medical officers—delivering them with printed, or plainly written, labels of directions. He shall from time to time prepare a list of whatever drugs, etc., may be wanted for the Dispensary, and enter the same in a book, which, with the order for the same, shall be signed by two of the medical officers; and all bills for drugs, etc., shall be examined with such order-book, and signed by the Dispenser and medical officers; and the order-book and bills shall be laid before the Committee of Management at its quarterly meetings.

X. MIDWIFE.—1. *Appointment.*—The Midwife, who should be duly qualified, shall be appointed by the Committee.

2. *Duties.*—To attend all members in their confinement who have an order from the Honorary Secretary requiring her attendance; and in cases of premature confinement, to attend members who pay five shillings to her at the time of sending, unless they are members of less than three months' standing, when they shall pay her seven shillings and sixpence. Sums received by her in this way to be handed to the Honorary Secretary or Treasurer. In cases of difficulty, she shall send for the medical officer under whom the member is entered.

3. *Remuneration.*—For each case of confinement attended she shall receive five shillings, unless in case of a member of less than three months' standing, when she shall receive seven shillings and sixpence.

XI. ASSISTANTS.—Such paid Assistants as Assistant Secretary, Collector, and Attendant, shall be appointed by the Committee of Management, as may be required; and in some localities the two former of these offices may be combined with that of Dispenser.

XII. ACCOUNTS AND AUDITORS OF ACCOUNTS.—The Treasurer shall keep a debtor and creditor account with the Committee of Management. The Honorary Secretary shall keep two distinct accounts:

1. The Subscribers' Fund Account; 2. The Members' Fund Account. The Auditors of Accounts shall annually, prior to the general meeting, audit such accounts, and shall call for and inspect all books and vouchers and documents relating thereto; and shall report the state of the books and the financial position of the Institution to the general meeting.

### ROYAL COLLEGE OF SURGEONS.

THE following is an abstract of the unconfirmed minutes of the meeting of the quarterly Council on the 19th instant. On the President reporting the death of Mr. Samuel Solly, F.R.S., since the last meeting of the Council, and adding that the vacancy thereby occasioned would be filled up at the annual meeting of the Fellows in July next, it was moved by Mr. SOUTH, the senior member of the Council, and seconded by Sir WILLIAM FERGUSON, Bart.—“That the President be requested to convey the sincere condolence of this Council to Mrs. Solly and her family, on the irreparable loss they have sustained by the death of Mr. Samuel Solly.”

The thanks of the Council were unanimously voted to Mr. Francis Kiernan, F.R.S., F.R.C.S., for his valuable donation of pathological specimens to the Museum.

The following report of the Committee on the financial arrangements proposed in the draft scheme for an Examining Board for England was read.

“Your Committee, appointed by the Council on the 24th of July last, to consider and report to the Council on the financial arrangements included in the appendix to the draft scheme for an Examining Board for England, have held two meetings, on the 31st of July last, and on this date, and, having considered the same, have agreed to the following report to the Council, viz:—

“That the following are the propositions contained in the appendix to the draft scheme, viz:—That one-half of the fees received for the examinations be appropriated to the payment of Examiners, Assessors, and other expenses incidental to the examinations, in such manner as the Committee of Reference may determine, subject to the approval of the co-operating medical authorities. That the remaining half of the fees received for the examinations be appropriated in the following manner: Towards the maintenance of the Museum of the Royal College of Surgeons as an institution of national as well as professional importance; for its unendowed professorships, and other allied expenses, one-third; in respect of medical qualifications to be granted, one-third; in respect of surgical qualifications to be granted, one-third.

“And that, in the opinion of your Committee, the said propositions should be adopted by the Council, with the following alterations, viz:—That the fees received for the examinations be appropriated to the payment of Examiners, Assessors, and other expenses incidental to the examinations, in such manner as the Committee of Reference may determine, subject to the approval of the co-operating medical authorities; and that the residue be divided in the following manner, viz:—Towards the maintenance of the Museum of the Royal College of Surgeons as an institution of national as well as professional importance; for its unendowed professorships, and other allied expenses, one-third; in respect of medical qualifications to be granted, one-third; in respect of surgical qualifications to be granted, one-third.

“RICHARD QUAIN, *Chairman.*”

It was moved by Mr. LE GROS CLARK, and seconded by Mr. CHARLES HAWKINS—“That the report of the Committee be adopted.” Thereupon the following amendment was proposed by Mr. HANCOCK, and seconded by Dr. HUMPHRY—“That the financial arrangements, as originally proposed in the appendix to the draft scheme for an Examining Board for England, be adopted in lieu of those contained in the report from the Committee.” The votes of the Council having been taken on the amendment, a majority was in its favour.

The sum of ten guineas was voted towards the memorial window to John Hunter in Kensington New Church, on the application of Messrs. Buckland and Merriman, the Honorary Secretaries.

The Secretary reported that Mr. Charles Hawkins had offered to the acceptance of the Council a small coloured engraving of the picture of Henry VIII presenting the Charter to the Barbers and Surgeons.\* The donation was accepted with thanks.

Mr. JOHN GAY gave notice of the following motion at the next meeting of the Council:—“That the proportionately large number of rejections at the preliminary examination for the diploma of the College is a fact which demands the serious consideration of the Council. And that a Committee be appointed to consider the subject, and to report to the Council thereon.”

\* This is a most interesting little picture, and apparently of great rarity, inasmuch as it is unknown to the authorities of the British Museum. Mr. South obtained permission to have it copied for his History of the College, now preparing for publication.

## ASSOCIATION INTELLIGENCE.

### COMMITTEE OF COUNCIL: NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the Queen's Hotel, Birmingham, on Tuesday, the 31st day of October, 1871, at One o'clock *precisely*, to elect a Secretary, and for other important business.

T. WATKIN WILLIAMS, F.R.C.S., *General Secretary* (pro tem.)  
13, Newhall Street, Birmingham, October 17th, 1871.

### SOUTH WALES AND MONMOUTHSHIRE BRANCH: ORDINARY MEETING.

THE next Ordinary Meeting of this Branch will be held on Tuesday, November 7th, at the Town Hall, Cardiff, at 1.30 P.M. The Council will meet at 12.30 P.M.

The Dinner will take place at 5.30 P.M.; and members may introduce professional friends to the meeting and dinner.

Members intending to read papers or notes of cases are requested to communicate the titles thereof as soon as possible to one of the Honorary Secretaries.

All members who purpose joining the dinner, will oblige by communicating their intentions to one of the Honorary Secretaries before the 31st instant.

ANDREW DAVIES,  
ALFRED SHEEN, M.D., } *Honorary Secretaries.*

October 4th, 1871.

### BIRMINGHAM AND MIDLAND COUNTIES BRANCH: GENERAL MEETING.

THE first general meeting of this Branch was held on October 12th, at 3 P.M.; present, OLIVER PEMBERTON, Esq., President, in the chair, and sixty-three members and visitors.

*New Members.*—The following gentlemen were elected members of the Association and Branch:—Mr. Evans, Sutton Coldfield; Dr. Jones, Coleshill; Mr. H. C. Moore, Lifford; Mr. J. P. Bradley, Birmingham; Dr. Philpot, Birmingham; Dr. R. L. Campbell, Stourbridge; Dr. Blackwood, Wednesbury; Mr. C. H. Greaves, Stafford; Dr. Crawford, Stafford; Mr. C. E. Handyman, Worcester; Mr. Charles Perks, Burton-on-Trent; Mr. Whitehead, Birmingham; Mr. Briggs, Birmingham.

*Communications.*—1. Dr. JAMES THOMPSON (Leamington) exhibited a specimen of Rupture of the Left Ventricle of the Heart. [See page 496.]

2. Dr. JAMES THOMPSON also showed a specimen of Hereditary Narrowing of the Rectum. The subject from whom the specimen was taken died at the age of forty-eight from chronic peritonitis, the result of the bursting into the peritoneal cavity of an abscess, situated between the upper surface of the right lobe of the liver and the diaphragm, and which appeared to have been caused by an old injury sustained in rowing some years previously. There was a family history of trouble in the lower bowels. During life, several attempts had been at various times made to pass a long tube through the rectum without success. When the specimen was fresh, it with difficulty admitted the passage of the forefinger; there was no induration, and several internal and external hæmorrhoids existed. During life, the finger passed into the rectum reached the opening of the tube, which felt like the os uteri partially dilated.

3. Mr. ARTHUR BRACEY exhibited a case of Congenital Cataract in a girl aged 12 years. When the pupil was fully dilated by atropine, the lens was found to be opaque in its centre only, and a margin of transparent tissue existed. This condition being regarded as permanent, an artificial pupil was made by iridectomy over the clear portion of the lens, and the patient now has excellent vision.

4. Mr. A. BRACEY also brought a patient in whose eye the Lens had become Dislocated into the Anterior Chamber.

5. Mr. LAWSON TAIT showed an ingenious little addition to the obstetrician's armamentarium in the shape of a Thimble for Rupturing the Membranes, devised by Dr. Gordon of Edinburgh. The thimble was most effective, and could, from Mr. Tait's experience, be used without injury.

6. Mr. CARDEN read a paper entitled Some Points in Surgical Experience. The paper gave an interesting account of Mr. Carden's amputation at the knee, with the various criticisms which it had called forth, and the result of the continued experience in its application. It was followed by an interesting discussion.

## REPORTS OF SOCIETIES.

## PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, OCTOBER 17TH, 1871.

T. HOLMES, F.R.C.S., Vice-President, in the Chair.

MR. HOLMES, in taking the chair in the absence of the President, offered a few remarks congratulating the Society on the continued and very marked prosperity of the Society. A proof copy of the *Transactions* for the past session was laid on the table.

Dr. PEACOCK exhibited a very interesting specimen of combined Aortic and Mitral Valvular Disease, consequent on rheumatic endocarditis. The specimen was taken from the body of a young man eighteen years of age, who had suffered from several attacks of acute rheumatism and one attack of chorea. Since the first attack of rheumatism, he had been subject to dyspnoea.

Dr. T. H. GREEN brought forward a specimen of Acute Interstitial Hepatitis obtained from the body of a boy ten years of age. Three weeks before admission into the Charing Cross Hospital, the patient was scarcely unwell, but two days before admission he vomited. He then became intensely jaundiced, and his stools white. Two days afterwards, the pupils dilated, delirium supervened, and he died in a few days comatose. After death, all the viscera excepting the liver were found to be healthy. The stomach and intestine were found full of blood. The liver was slightly diminished in size. In the hilus were found two enlarged glands pressing on the common bile-duct. The gall-bladder contained half-an-ounce of bile. Microscopically, there was seen cellular infiltration of the interlobular spaces; also increase in the fibrillated tissue. The hepatic cells were very little altered. Dr. Green was of opinion that the change in the liver was inflammatory, but the peculiarity of the jaundice and the absence of bile from the stools were probably due to the pressure of the glands.—Dr. MURCHISON asked what the temperature was; he thought Dr. Green was probably correct regarding the cause, but if no jaundice had occurred, what would have been the diagnosis? He had found that the temperature was barely raised in some cases of atrophy of the liver.—Dr. GREEN, in reply, stated that there was no pyrexia.

Dr. MURCHISON exhibited some Hydatids which had been successfully removed by operation during life from the Abdominal Cavity of a woman affected with Multiple Hydatid of the Peritoneum. The patient, a woman aged 29, had been under his care in the Middlesex Hospital. She was rather emaciated, but enjoyed good health. The girth of the abdomen was thirty-four inches. There was no ascites, and no solid mass; but the surface of the abdomen presented a nodular feel, the nodules varying from the size of a cherry to that of a fist. Some were fixed; others, again, were movable. They were closely aggregated together throughout the abdomen, and hydatid vibration was felt. There was no tenderness at any part. These symptoms led Dr. Murchison to believe that the case was one of multiple hydatid of the peritoneum. The patient would not submit to an operation, and refused to remain in the hospital. She saw Mr. Spencer Wells, who punctured the abdomen. He afterwards opened the abdomen, and removed three or four pounds in weight of hydatids. For some months afterwards she remained well, but the patient has since been lost sight of. It appeared from the history obtained, that the patient had been married at eighteen years of age. She was delivered of a child a year afterwards; and, three months later, symptoms referable to the disease presented themselves. She was suddenly seized with pain under one side, where a lump appeared, with symptoms of peritonitis. This passed off; but she had several attacks of a similar character afterwards, during which period she bore four children.

Dr. MURCHISON brought forward a second case of Hydatid of the Peritoneum. The patient was a man forty-five years of age, and remained in the Middlesex Hospital from March 30th until April 10th. The abdomen was enlarged; and six different masses were felt, some of them being very superficial. The first symptom which drew the patient's attention to the disease was pain in the abdomen. Three drachms of fluid were drawn off from one of the cysts; it contained abundance of chlorides, but no hooklets.

A prolonged and interesting discussion ensued on these two cases of hydatid. The PRESIDENT observed that, so far as he knew, the case of the woman was the first in which hydatids had been removed by operation.—Dr. WILKS alluded to a case of multiple hydatid of the abdomen which had been removed at Guy's Hospital.—Dr. PHILLIPS gave the history of this patient in some detail. The patient was admitted for ovarian dropsy; but, on being operated upon, it was discovered that the case was one of hydatids. They were contained in

a cyst and not scattered over the abdominal wall as in Dr. Murchison's case. Dr. Wilks, in remarking on the primary seats of the disease, asked if they ever began in the abdominal wall, and if so, in what tissue.—Dr. MURCHISON replied that there was nothing to shew definitely that the liver was affected primarily in his first case; still the symptoms pointed to that organ being first attacked.—Dr. MOXON alluded to a case of multilocular hydatid of the spinal column, and Dr. MURCHISON to a similar one in the Museum of the Middlesex Hospital.

Dr. ROBINSON brought forward a case of some obscurity which he believed to have been an example of Acute Laryngitis, producing sudden death by asphyxia.

Dr. PAYNE shewed a gland from the body of a patient who died from Lymphadenoma. The disease had lasted three years. From time to time there was considerable febrile disturbance; and last year symptoms at first of paraplegia, and latterly of loss of motor power in the left arm, presented themselves. Consolidation of the left lung and diarrhoea supervened. The specimen showed microscopically the second stage of the changes in which these glands undergo thickening and increase of the network passing through the gland. In the general history of lymphadenoma there is first hypertrophy of lymph-elements, which is afterwards destroyed by the increased fibrous stroma.

Dr. GOODFELLOW exhibited an interesting specimen of Aneurisma Pouch, originating from the wall of the heart near one of the aortic semilunar valves. The aortic valves and aorta were greatly diseased, and the heart weighed sixteen and a half ounces. The subject of the disease was a porter, forty-eight years of age, who had suffered only a few months previously from sciatica, when symptoms of dyspnoea supervened, which increased until a fortnight previously to his admission into the Middlesex Hospital.

Dr. MURCHISON exhibited a specimen of Cardiac Aneurism, which was filled with dark coagulum, and bulged into the right ventricle. The patient had complained of cardiac pain and palpitation for several years. There was a loud systolic murmur over the whole heart and at the angle of the scapula; but there was no disease of the mitral or aortic valves. Albuminuria latterly supervened, and the patient died of dropsy.

Dr. MOXON brought before the notice of the members the fact that in the bodies of persons who have died with old stricture of the urethra, wasting disease of the kidney is frequently found; and he asked the opinion of the Society whether suppurative kidney-disease is not curable and frequently recovered from.—The PRESIDENT believed that it was not necessarily fatal.—Further discussion on this interesting subject was prevented by the lateness of the hour.

## OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, OCTOBER 4TH, 1871.

J. BRAXTON HICKS, M.D., F.R.S., President, in the Chair.

Dr. BARNES presented, on behalf of Dr. Boddaert, of Brussels, the Lever employed by Dr. Boddaert; also a Memoir on the Rational Use of Forceps and Lever by the same gentleman. The lever was a solid bar, nearly straight, and without fenestra; it could only be a lever, and in no sense a tractor.

Dr. BARNES exhibited a specimen of an Iliac Artery obstructed by a clot. The case was described by Mr. Williams, of Truro. The subject was seized during an abortion with prostration, coldness, failure of pulsation, and gangrene of the leg of the side on which the artery was plugged.

Mr. SPAULL exhibited a foetus, the subject of Hydrocephalus. The child presented by the breech, and the head had to be perforated.—Mr. MITCHELL had met with several cases of the kind; in one of them he had perforated the head and delivered the child with forceps, all having been head-presentations.—Dr. G. R. P. MURRAY thought that in such a case as that related, much diagnostic information could be obtained by placing the hand on the lower part of the abdomen and feeling the unusually large size of the uterus after the birth of the extremities and body of the child. The possibility of the existence of twins should, however, be remembered.

The PRESIDENT read a paper on the Intermittent Contractions of the Uterus during Pregnancy; their physiological value and assistance in diagnosis. He shewed as the result of eight years' constant observation, that the habit of the uterus was to contract at intervals of from five to twenty minutes, and then to relax. These contractions, he said, lasted about three or five minutes, although under circumstances of irritation they might continue longer, and even in diseased states of the ovum were almost continuous. Only one apparent exception had been noticed, in a case of paraplegia, in which the contractions were not noticed. They were observable as early as the third month of preg-

nancy. They were not due to the irritation of examination; for, as frequently as not, the uterus would be found hard on first handling it. Dr. Hicks thought that at least two advantages were derived, physiologically, from these contractions: the one to supplement the heart's impulse in a part remote from its influence; the other to assist the ultimate disposition of the fetus. He discussed at length the assistance which these contractions gave the practitioner in the diagnosis of extra-uterine from uterine tumours, of uterine tumours from pregnancy, and of extra- from intra-uterine pregnancy.—Dr. BARNES called attention to the work of Dr. Tyler Smith, in which the peristaltic movements of the pregnant uterus were well described.—Dr. HICKS said the extract quoted from Dr. Tyler Smith's work had escaped his notice. But the peristaltic movements referred to by Dr. Smith were the result of external excitation.

Dr. COPMAN, of Norwich, related three cases which he had met with in practice. The first was one of Induction of Premature Labour on account of excessive vomiting; the second, a case of Large Fibrous Polypus of the Fundus Uteri; and the third, a case of Procidencia Uteri in a maiden lady.—Dr. BARNES agreed with Dr. Copman, that the introduction of a bougie or catheter into the uterus was the best mode of provoking labour, but it could not be depended upon to complete the process.—Dr. PROTHEROE SMITH referred to an instrument shewn him by Dr. Tarnier, of Paris. It consisted of a metal grooved director, about eight inches long, carrying a tube of India-rubber, thin at its distal extremity. This was introduced into the uterus, towards the fundus, separating the membranes. It was then distended with water, so as to form a bulb-shaped bladder when the metal director was withdrawn. Uterine action usually set in within a few hours.—Dr. PLAYFAIR generally used a simple catheter, which he passed between the membranes and the uterine wall; but on more than one occasion he had seen it fail.—Dr. BRUNTON had induced premature labour successfully nine or ten times by injecting warm water into the uterus. He had, however, now given up that method, both on account of the danger said to attend its use, and because in one case it totally failed. He now used a bougie (No. 12), in which no eye had been cut.—Dr. G. C. P. MURRAY expressed his belief in the value of the plan of injecting water into the uterus.—The PRESIDENT said that the safety of the child depended on two conditions: the rapidity with which the uterus came into action, and the freedom with which the child passed through the os uteri.—Dr. WILTSHIRE suggested the desirability of inducing premature labour at a period which corresponded to a menstrual epoch.—Dr. ROGERS had early in his career been accustomed to puncture the membranes high up, so as to save some of the liquor amnii, having first dilated the cervix with sponge-tents. Of late years he had used a long catheter with an opening at its rounded extremity.

#### MEDICAL SOCIETY OF LONDON.

MONDAY, OCTOBER 16TH, 1871.

ANDREW CLARK, M.D., President, in the Chair.

THE President made some introductory remarks.

*Killing Animals without Pain.*—Dr. B. W. RICHARDSON read a paper on the possibility of destroying animals intended for human consumption, without the infliction of pain. He recommended the following agents for producing insensibility: 1. Hydramyle and bichloride of methylene; 2. Carbon disulphide and methylene bichloride; 3. Chloroform or methylene and coal-gas. When a butcher kills an animal in the usual way, bleeding occurs; there are primary syncopeal convulsion after the loss of forty ounces of blood, and fatal convulsive paroxysm after the loss of about ten ounces more. If the vapour of two drachms of either of the agents referred to were administered, narcotism was produced, and the primary convulsion was suspended or much reduced; the second was an entirely painless phenomenon. No odour or taste of the anæsthetic was left in the flesh of the animal.

*Hypervæmia of the Lower Limb.*—Mr. GAY read a paper on this subject. The term was used to express a condition in which there is a deficiency in the veins of the saphenous system, as hypervæmia might be used to express an excess in the development of these veins. In the latter, especially with varicosity, the limb was usually lean, and the outlines of bone, muscle, and tendon, were, as a rule, sharp and well defined. In hypervæmia, these outlines became gradually effaced, the skin became dusky, the whole limb dense or brawny, and muscular action difficult and painful. With the exception of perhaps a few dilated or varicose venous twigs below the ankles, or on the dorsum of the foot, there was scarcely a vein to be seen. As the disease advanced, the subdermoid fat layer became denser and lost its elasticity. Its remote causes were disease of the vessels, such as phlebitis, insufficient muscular exercise, systemic asthma, etc. Degeneration and conse-

quent incompetence of the saphenous veins and their branches was its direct or exciting cause. Secondly, it was presumed, the deep trunk veins became dilated, their valves partially inert, and fatty deposit and degeneration took place in the muscles and their connective tissue. The grounds for this inference were: (a) that functional deterioration of the saphenous system, through thickening, atrophy, retrecissement, or thrombus, was an occasional pathological fact; (b) and that saphenous inefficiency as shown by a varicose condition of the venous radicles, as well as by a dusky colour of the skin, otherwise than from melasma or scleroderma, were habitually associated with and indicated dilatation of the deep trunk veins. The author remarked that the venous system was double—superficial and deep, or main and complementary; the former playing to the latter the part of a waste-pipe, or compensating system, ready to relieve it when its vessels were unduly filled. The deep veins constituted the real venous system; therefore, the current through these veins, in the healthy performance of the double circulation, was maintained by a combination of forces, of which voluntary muscular was not a necessary co-efficient. The current through the complementary veins, on the other hand, received, in the limbs more especially, its principal impulse from voluntary muscular action. If its vessels became inefficient, the surplus quantity of blood due to muscular exercise was poured into the deep veins with a force that resulted in dilatation, valvular incapacity, muscular deterioration, and other changes. The forces which determined the returning current of the blood were complex: the principal of them were the heart's action, arterial elasticity, and the influence of the nervous system. Of these, each might separately be cut off, and yet the blood would find its way back to the heart. Moreover, the blood passed from the arteries into the veins without the aid of any of these forces. Mr. Gay believed that there was a sort of molecular force which existed in connection with muscular tissue or sarcode, and that to it the venous current was mainly due; that in fact, as an agent in the circulating system, it was to the capillary very analogous in some respects to what the heart was to the arterial system. As the deep or main system of veins was associated with the nutritive processes, so the superficial or complementary was essentially eliminatory. From these veins in the lower limb dropsical effusion took place; and it was not improbable that in other dropsies, as of the pericardium, pleura, or peritoneum, the fluid escaped from veins of the complementary system. The treatment was the reverse of that ordinarily employed, viz.: an entire freedom of the limb from all compresses, enforced walking exercise, begun in moderation and periodically increased, hot applications, especially hot sea-water to the limb, and perhaps the internal administration of liquor potassæ; in short, the use of all those measures, hygienic and therapeutic, which could, on the one hand, restore the circulation of the limb, and on the other, relieve it of its superabundant fat.

#### MANCHESTER MEDICAL SOCIETY.

WEDNESDAY, OCTOBER 4TH, 1871.

JOHN THORBURN, M.D., President, in the Chair.

*Retrolabular Neuritis.*—Dr. SAMELSON related the history, together with the *post mortem* account by Mr. James Taylor of Chester, of the following case. A man, aged 30, had epileptic fits in 1868, and again, followed by delirium, about Christmas 1870. On the 12th of March last, the sight of the right eye was suddenly reduced to mere perception of light. The ordinary ophthalmoscopic phenomena of neuro-retinitis were but faintly marked; but the macula lutea was occupied by a dark red spot, such as is commonly observed in cases of embolus of the central artery of the retina. There were persistent pain and tenderness on percussion above the right orbit; the eyeball was painful on moderate pressure, and on being directed upwards or outwards. All the morbid symptoms gradually abated within three weeks, under the repeated application of leeches to the forehead. The sight was again equal to No. 20 of the Moorfields test-types. In April, he had epileptic fits, followed by delirium. Death occurred on the 27th. The whole of the pia mater was found to be intensely injected; the arachnoid at the base of the brain was very thick, white, and opaque; and behind the chiasma was a mass a third of an inch across and an eighth of an inch thick, of almost cartilaginous hardness, apparently part of the thickened arachnoid. On cutting through into the subarachnoid space, some gelatinous material bulged, very similar to the coagulated fibrine occasionally found in the peritoneal cavity. The surface of the brain here was rather brown and softer than natural. The pituitary body, very red and granular, completely filled up the sella Turcica. The sheaths of the optic nerve were much thicker and denser than usual; and this seemed to be a continuation of the thickening of the arachnoid. The eye could not be obtained for examination.

*Paresis of the Third Nerve.*—Dr. SAMELSON related the case of a girl 14 years of age, who after an illness of five weeks, consisting in headache, languor, and inappetence, was in April last seized with slight ptosis, divergence, and mydriasis, affecting the left eye. After a severe attack of headache and a fall out of her bed on the night of the 27th of April, she was found dead in the early morning. On inspection of the cranial cavity, fully a tumblerful of dark and for the most part fluid blood was upon the base of the skull, collected in the fossæ occipitales. The right lateral ventricle contained a small hydatid.

*A Shot in the Eye.*—Dr. SAMELSON showed the recently enucleated left eyeball of a farmer, who in April last was accidentally wounded, when the sclerotic was ruptured near its temporal junction with the cornea. Besides total detachment of the retina, a shot was shown to be impacted within the ciliary structures, behind the nasal corneo-scleral junction.

*Extraordinary Case of Fœtation.*—Dr. J. O. FLETCHER showed a full-grown fœtus which had been removed from the body of a woman aged 57 by Mr. Heathcote, from whom and from Dr. Whitehead, who had seen her during life, the following history was obtained. Mrs. — had had five previous pregnancies—three living children. She ceased to menstruate when she was 31, in March; and, in the following December, labour-pains came on, and lasted for two days. The waters were said to have come away; but no presentation could be felt. After the cessation of labour-pains, the swelling was said to have diminished. The lochia continued to flow for four months, and then ceased, the menses recurring regularly from that time till the age of 48. The abdominal tumour remained, and the patient complained of feeling a cold dead lump in the belly. Dr. Whitehead, who examined her last July, found the os uteri shapeless and turned to the left side, but could not detect the child. Dr. Fletcher remarked that the case at first looked like a tubal fœtation; it had, however, many of the characters of interstitial fœtation. A committee was appointed to examine the specimen, and to report upon it at next meeting.

*Subcutaneous Section of Neck of Femur.*—Dr. HARDIE showed a case in a woman 22 years of age. The operation was performed for ankylosis with malposition. The patient had now a perfectly straight limb, and could walk about with great freedom.

*Congenital Cystic Tumour.*—Dr. HARDIE showed a child from whose neck he had removed a tumour of this description.

*False Conception.*—Dr. HADDON related a case. The patient, 28 years of age, had borne four children, one of whom was born in a state of decomposition a month past the full time. Menstruation ceased on 7th April, 1871, having on that occasion been more painful, more profuse, and four days longer in duration than usual. On 6th June, the woman having been in the interval without discharge and with none of the usual feelings of pregnancy, pains set in, accompanied by a discharge at first pale, afterwards becoming bloody. On 14th June, a pear-shaped mass, of the size of a small hen's egg and of firm consistence, was expelled from the uterus, after which the patient rapidly recovered. On section the centre of the mass was found to be occupied by a cyst with a smooth lining membrane containing a little clear serum. The mass was, in Dr. Haddon's opinion, an old clot of blood; and, to show that such clots could be formed in the uterus independent of conception, he referred to "polymenorrhœic stratifications", as figured by Dr. Granville in his *Illustrations of Abortion and the Diseases of Menstruation*, and to Dr. Grailey Hewitt's *Diseases of Women*.

*The Use of the Ophthalmoscope in Epilepsy.*—Dr. HADDON had examined the eyes of eleven epileptics, hoping to detect some peculiarity which might assist in the prognosis of the disease. In ten of these, he found a dark rim surrounding to a greater or less extent the clearly defined margin of the optic disc; in the eleventh, who had fewest fits, no trace of such a rim could be detected. The rim was found well-marked in a masturbator; while it was entirely absent in the eyes of many healthy friends. In Dr. Haddon's opinion, this appearance, although not perhaps peculiar to epilepsy, yet pointed to some disease or derangement of nutrition which might assist in the study of its pathology.

*Complete Evulsion of the Scalp.*—Mr. STOCKS showed the entire scalp of a mill girl, 23 years of age, which was accidentally torn off by machinery five weeks ago.

*Application of Heat or Cold to the Body.*—Dr. W. ROBERTS exhibited a pad designed to apply regulated and sustained heat or cold to the surface of the body. The pad consisted of a flat coil of continuous and very thin India-rubber tubing cemented to a strong canvas backing. Through this a current of water, of any temperature, could be passed by connecting one end of the tube with a vessel of water (warm or cold) placed on a raised level, and putting the other into a vessel on the

floor. Dr. Roberts had had two such pads constructed: one a foot in diameter for local effects, and another measuring three feet by two to place under the back or round the trunk to obtain a general effect on the temperature of the body.

## THE POOR-LAW MEDICAL SERVICE OF GREAT BRITAIN.

### POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

The Annual Report of the Poor-law Medical Officers' Association has been delayed through the indisposition of Dr. Joseph Rogers. From the balance-sheet, it appears that there is but £52 : 7 : 10 in hand. The arrears of subscription are considerable. Members are asked cordially to co-operate in the work of the Association by forwarding their subscriptions, and communicating with their parliamentary representatives, and petitioning, when the time shall arrive, in favour of the Poor-law Medical Bill which Mr. Corrance intends to introduce next session. Particulars of the Bill and forms of petitions will shortly be published; and the opinions and criticisms of the Poor-law medical officers will be invited.

The subscription to the Poor-law Medical Officers' Association is *five shillings* a year, and, in order to simplify accounts, will in future become due on the 1st of January. It is payable to J. Wickham Barnes, Esq., 126, Gower Street, Bedford Square, London.

### VACCINATION.

DR. PITT has been requested by the Norwich Board of Guardians to visit the parish school containing nearly 300 children, and inspect and report as to the condition of the vaccination. Dr. Pitt found twenty-six children unvaccinated. He furnished his report, for which he charged one guinea. The guardians have appreciated the service by withholding the payment until it is approved of by the Local Government Board. This appears to be an extra duty, and it is to be hoped that the Local Government Board will at once approve of the important service of Dr. Pitt and sanction the payment of the fee.

## OBITUARY.

### JAMES STANLEY CHRISTIAN, L.R.C.P.

DR. CHRISTIAN was the third son of James Christian, Esq., of Sligo, who held the then responsible and lucrative office of clerk to the grand jury. His sudden death left a large family very scantily provided for; and the subject of this notice had many and great difficulties to surmount in entering the medical profession. He always attributed his subsequent success in life to the energy and example of his eldest sister, who survives him, and who, with limited means, devoted herself to the education and support of the younger children of her parents.

Mr. J. S. Christian became a member of the Royal College of Surgeons in 1837, an extra-licentiate of the Royal College of Physicians of London in 1841, and a Fellow of the College of Surgeons of Ireland in 1844. After practising for some time in the county of Monaghan, where he made many friends, he came to England, and practised near Deal in Kent. He ultimately settled at South Kensington, where he has been well known and esteemed for upwards of twenty years, and where he succeeded in establishing one of the best practices in the west end of London.

Dr. Christian married, in 1857, Julia, daughter of the late E. L. Ogle, Esq.; he had one child, who died in 1867.

His devotion to his professional duties must be considered as the remote cause of his premature death. He neither allowed himself that relief from excessive labour, nor that support for an overworked system, which he constantly prescribed to his patients. On Sunday, the 8th instant, as he was seated conversing with his brother-in-law, Mr. Ashurst, at the house of the latter in Kensington, he was suddenly seized with paralysis of the left side; and though Drs. Sieveking, Barclay, and Seaton were promptly in attendance, and administered remedies to which at first the disease appeared to be yielding, on the night of the 14th an unfavourable change took place, and he expired in the house of his brother-in-law on Tuesday morning, the 17th instant. His death leaves a void difficult to fill, in a very numerous circle of friends: all his patients were such.

## AUGUSTUS G. GREAVES, M.R.C.S., DERBY.

MR. GREAVES died somewhat suddenly on October 1st, from thoracic aneurism. He had been in failing health for the last three years, being at times quite unable to attend to his professional duties. He had practised as a surgeon in Derby about thirty-five years. For a great portion of that period he was one of the surgeons of the Derby Provident Dispensary, and up to the time of his death held the appointment of medical attendant of the Diocesan Training College at Derby. Few men had more friends, or were more generally esteemed.

## JOHN BAIN, L.F.P.S. Glasg., JOHNSTONE, RENFREWSHIRE.

MR. JOHN BAIN died on September 22nd, at the early age of twenty-seven, from typhoid fever, of ten days' duration. He commenced his professional career by acting as Surgeon for about a year in the anchor liner, *Britannia*. He was then appointed House-surgeon for the Paisley Infirmary, from which he, sixteen months ago, removed to Johnstone to commence general practice. During the short time he was in Johnstone he made many friends, by whom his early removal is deeply regretted. He was genial, warm-hearted, and unwearied in alleviating the distress of others, and he has died in the discharge of his duty.

## MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—At a meeting of the Council of the College on the 19th instant, Mr. Robert Boyle Travers, of Rosellen, co. Cork, was admitted a Fellow; and Mr. Richard Bowes, of Richmond, Yorkshire, was elected a Fellow of the College. The gentlemen are both members of the College: their diplomas bearing date respectively May 21st, 1841, and November 4th, 1831.

The first examination for the present session for membership of the College will take place on the 4th proximo for the primary, and on the 10th for the pass.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, October 19th, 1871.

Coxey, Richard John, Northampton  
Kendon, Joseph, Croydon  
Rushmore, Edmund, Leeds  
Wall, William Barrow, Wedmore, Somersetshire

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the monthly examination, held on October 10th, 11th, and 12th, the following candidates were successful.

For the Licence to Practise Medicine.—Sydney Richard Smyth, William Robert Hughes, Henry Thompson Cox, Nicholas Skottowe Smith, Patrick Freebern Gavin, and Frederick A. Ernest Barnardo.

For the Midwifery Diploma.—Richard George O'Flaherty, Halton Smyth, Sydney Richard Smyth, Wm. Robt. Hughes, Henry Thompson Cox, Nicholas Skottowe Smith, Fred. A. E. Barnardo, and Patrick Freebern Gavin.

APOTHECARIES' HALL, DUBLIN.—At the preliminary examination in Arts, held on October 19th, the following gentlemen received certificates entitling them to commence their medical studies.

James Ezelle Nagle, James Henry O'Brien, Michael Cormac Cullinan, Wm. Moore, Wm. Dunne, James Maurice M'Loughlin, Michael Joseph O'Shea, Robert Edward Donovan, Henry O'Neill, John Albert O'Meehan, William Oliver Dawson, Peter Mulvany, and Francis John Lynch.

The following gentlemen, having passed their professional examinations, obtained the licence to practise.

Hugh Orr, Virginia, on Cavan; Francis Augustine O'Reilly, Killeshandra, co. Cavan; John Peacocke, Limerick; and Thomas Wm. Myles, Limerick.

## MEDICAL VACANCIES.

THE following vacancies are announced:—

ALNWICK INFIRMARY—Surgeon.  
ADMINISTER UNION, Devon—Medical Officers for the Colyton and Shute Districts.  
CARDIFF, Parish of, Lanarkshire—Medical Officer for the Western District.  
CARDIGAN UNION—Medical Officer for District No. 3.  
CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn Road.  
CHESTER GENERAL INFIRMARY—Dispenser.  
CORK UNION—Medical Officer for the Blackrock Dispensary District.  
DERBY PROVIDENT DISPENSARY—Two Medical Officers.  
EAST PRESTON UNION, Lancs.—Public Vaccinator for District No. 3.  
EARTY UNION, Kent—Medical Officer for the Deal District.  
EXETER LYING-IN CHARITY—Surgeon.  
FIMBURY DISPENSARY, Brewer Street North—Physician; Resident Medical Officer.

FULHAM UNION—Medical Officer and Public Vaccinator for District No. 5; £50 per annum, and extra fees.  
GLENDALE UNION, Northumberland—Medical Officer for the Lowick District.  
GREAT NORTHERN HOSPITAL, Caledonian Road—House-Surgeon.  
GREAT OUSEBURN UNION, Yorkshire—Medical Officer for the Workhouse; £30 per annum. Medical Officer and Public Vaccinator for the Great Ouseburn District; £20 per annum, and extra fees.  
HONITON UNION, Devon—Medical Officer for District No. 8.  
HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton—Resident Clinical Assistant.  
HULME DISPENSARY, Manchester—House-Surgeon: £130 to £150 per annum, apartments, coal, gas, and attendance.  
KEIGHLEY, Yorkshire—Medical Officer of Health.  
LIVERPOOL INFIRMARY FOR CHILDREN—House-Surgeon: £80 per ann.  
LONDON FEVER HOSPITAL—Physician.  
LOUDOUN, Ayrshire—Medical Officers for the Newmilns and Darvel Districts: £30 per annum each.  
METROPOLITAN DISPENSARY, Fore Street—Surgeon.  
MIDDLESEX HOSPITAL MEDICAL COLLEGE—Lectureship on Materia Medica.  
NEWPORT, Pembrokeshire—Admiralty Surgeon and Agent; Certifying Factory Surgeon.  
NORTH DEVON INFIRMARY, Barnstaple—House-Surgeon: £100 per annum, board, lodging, etc.  
NORTH UIST, Inverness-shire—Parochial Medical Officer: at least £200 per ann.  
OLD KILPATRICK, Dumbartonshire—Medical Officer for the Western District: £25 per annum; and Sanitary Medical Officer: £5 per annum.  
ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road—Surgeon.  
ROYAL SURREY COUNTY HOSPITAL, Guildford—House-Surgeon: £75 per annum, board, residence, and washing.  
ST. GEORGE DISPENSARY, Mount Street, Grosvenor Square—Physician-Accoucheur.  
SMETHWICK, Staffordshire—Medical Officer of Health.  
TYRRE, Aberdeenshire—Parochial Medical Officer.  
WEXFORD UNION—Medical Officer for the Wexford Dispensary District: £120 per annum, and Registration and Vaccination Fees.

## MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

DONOVAN, Humphry J., M.D., appointed Medical Officer, Public Vaccinator, and Registrar of Births, etc., for the Emlagh Dispensary District of the Caherciveen Union, co. Kerry, vice W. J. Kisby, L.F.P.S. Glasg., L.A.H. Dub.  
DORAN, Alban H. G., Esq., appointed House-Surgeon to St. Bartholomew's Hospital, vice A. J. Hogg, Esq.  
FAGGE, Charles Hilton, M.D., appointed Physician to the London and Westminster Bank, in the room of the late \*Samuel Solly, Esq., F.R.S.  
MACCALL, William N., M.D., appointed Assistant Medical Officer to the Clinical Hospital and Dispensary for Children, Manchester.  
MAYNE, Charles, Esq., elected Medical Officer for the Killiney Dispensary District of the Rathdown Union, co. Dublin.  
PARRY, Lloyd Davenport, L.R.C.S. Edin., appointed Medical Officer and Public Vaccinator for Sandy, Orkney, vice T. B. Stokoe, M.D.  
\*PARKER, R. W., Esq., appointed House-Surgeon to the London Hospital.

## BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

## MARRIAGES.

HALL, W., Esq., of Atherstone, to Ellen Hall, daughter of \*J. HIGGINBOTTOM, Esq., F.R.S., of Nottingham, at Hastings, on October 12th.  
WRIGHT, J. Brampton, M.D., of Wellingborough, to Caroline Addison, second daughter of W. TOLLER, Esq., of Kettering, Northamptonshire, on October 12th.

## DEATHS.

FAITHORN, George, Esq., Surgeon, at Chesham, Bucks, aged 64, lately.  
FAWCUS, James, M.D., Inspector-General of Jails, Lower Provinces, Bengal, in North Shields, of pneumonia, the sequel of fever caught in Calcutta, aged 38, on October 11th.  
JONES.—On October 23rd, at Cleobury Mortimer, Salop, aged 65, Anne, wife of \*William Weaver Jones, Esq., Surgeon.  
\*LOWDELL, George, Esq., Surgeon to the Sussex County Hospital, at Brighton, lately.  
\*SHANNON, James, M.D., late of Ennistymon, county Clare, at Dublin, aged 60, on October 2nd.

TAUNTON AND SOMERSET HOSPITAL.—The Treasurer's account shows a deficiency of £534, besides £116 on the building fund account.

MISS BRAKENBURY of Brighton having given £5,000 for the erection of a new building for the Ardwick and Ancoats Dispensary, Manchester, on condition of a site being obtained, the Committee are raising a fund for that purpose and for furnishing, etc. The sum of £1,500 has been already subscribed.

BEQUESTS, DONATIONS, ETC.—Baron Berners has bequeathed £1000 to the Leicester Infirmary, and £1000 to the Leicester and Rutland Lunatic Asylum.—Mr. William Stevens Louch has bequeathed £1000 each to St. George's Hospital, Westminster Hospital, Middlesex Hospital, St. Mary's Hospital, and the Brompton Hospital for Consumption, etc.; and £200 to the Victoria Infirmary for Sick Children, Chelsea.—Mr. James Staynor, of Ilminster, as the representative of a Committee of Gentlemen, has sent £400 to the Taunton and Somerset Hospital.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY** ..... Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**TUESDAY** ..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**WEDNESDAY**... St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**THURSDAY**... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**FRIDAY** ..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.

**SATURDAY**... St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY**.—Medical Society of London, 8 P.M. Mr. Victor de Méric, "A Case of Traumatic Phthisis." Dr. Alfred Willshire, "Edema of the Lung following Small-pox." Mr. W. F. Teevan will exhibit some Instruments; Mr. John Pennefather, "On the Sense of Hearing" (with illustrations).

**WEDNESDAY**.—Royal Microscopical Society, 8 P.M. Dr. Braithwaite, "On Bog Mosses"; Dr. J. J. Woodward, U.S. Army, "On the Scales of Deguria Domestica as seen with Black-ground Illumination"; Mr. W. S. Kent, "On some new Infusoria."—Obstetrical Society of London, 8 P.M. Dr. Rasch, "On a novel way of using the Uterine-Sound in Flexions of the Uterus"; Mr. Eugene Goddard, "On a Case of Ovariotomy during Pregnancy"; Dr. Conrad (of Pesh), "On Prolapse of the Female Genital Organs."

**THURSDAY**.—Harveian Society of London, 8 P.M. Dr. C. Handfield Jones, "Notices of some of the less usual Phenomena in Chronic Alcoholism."

## EXPECTED OPERATIONS AT THE HOSPITALS.

**WEST LONDON HOSPITAL**, Saturday, October 28th, 3 P.M. Lithotomy by Mr. Teevan.

## NOTICES TO CORRESPONDENTS.

**ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.**

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**TO PURCHASERS**.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with half-penny stamps for the amount.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

**DR. TAYLOR (Cardiff)**.—Mr. Morgan's very able pamphlet will no doubt, in the first instance, receive the attention of the Committee of Council. We should like to hear the opinions of the most experienced members of the Committee of Council before commenting on his ingenious proposition.

## MEDICAL ETIQUETTE.

**WE** have before us a statement from Dr. Royston, of Westbourne Park, London, referring to the conduct of Mr. Delamark Freeman of Talbot Road. He left that gentleman in charge of his patients during a professional holiday. He states that, on his return, that gentleman continued to attend two of those patients against his wish; and, in a third case, he asked a lady whom he had delivered for Dr. Royston, whether she should in future employ Dr. Royston. We need not say that such conduct as that here described is in the highest degree unprofessional and improper; and we can only hope that Mr. Freeman will be able to clear himself in some way of this very grave charge. Conduct such as is described would be destructive of all professional confidence, and involves, indeed, very serious considerations of honour. We shall hope to hear from Mr. Freeman on the subject.—Notice of another correspondence on a subject of etiquette, between Messrs. Hiff and Tunaley, is unavoidably postponed.

**"A WOULD-BE INDIAN SURGEON"** complains that the competitive examinations for the Indian Medical Service are not held sufficiently often. They are announced as likely to take place twice a year; none has taken place for two years. This surgeon loses sight of the changes which have taken place consequent on the amalgamation of the two services. The demand must regulate the supply in every service.

**VIR LENTUS**.—It is usual for all the medical men of the locality to have the option of attending the patients whom they send into the village hospital.

**NOTICES of Births, Marriages, Deaths, and Appointments, intended for insertion in the JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.**

## TREATMENT OF CATARACT BY PHOSPHORUS.

**SIR**.—Would some of your numerous correspondents kindly inform me if a solution of phosphorus in oil of almonds, as recommended by Dr. Tavinot, has been used in this country for the removal of cataract; and, if so, with what result. Any information on this subject would greatly oblige. I am, etc., A MEMBER.

## PUNCTURE IN TYMPANITES.

**SIR**.—In justice to Dr. Davey, of Bristol, will you allow me to correct an error in my paper on Punctures of the Colon, in last week's JOURNAL? Dr. Davey's case was recorded in the JOURNAL of August 21st, 1869, and not 1870, as I have inadvertently stated. The priority of this mode of treatment in this country appears to belong to Dr. Davey, as his case was operated on on the 7th October, 1868; while to Dr. Clifford Allbutt belongs the first published record, in the *Practitioner*, February 1869, of a case operated on by Mr. Teale, on January 5th, 1869.

I am, etc., J. HANCOCKE WATHEN.

## DISINFECTANTS.

**SIR**.—Dr. Domett Stone, in the *Times* of September 28th, makes the following assertion:—"That earth is a disinfectant, no one will deny." I most assuredly deny it. Indeed, this and nearly every other substance mentioned in the letter of Dr. Stone and other writers on the subject of late have no title to the name disinfectant. Disinfection "is the process of dispelling and neutralising contagious miasmata." Most of these substances are simply antiseptics and deodorisers—that is, the decomposers of certain gases, the product of putrefying animal and vegetable matter, in this way preventing the ill consequences that might arise from imbibing these noxious gases, either by inhalation or otherwise; some of them also delaying or preventing putrefaction. Now these are very different from those qualities required for the decomposition of a fresh non-putrid animal poison, such as the poison of scarlet fever, small-pox, cow-pox, etc. These poisons when putrid are as innocuous as animal poisons. May we not then very well ask ourselves the question, as the substances in common use are not disinfectants, but antiseptics, deodorisers, and antiputrescents, whether they do not act in the way the very reverse from what is intended, and, instead of hastening the destruction of specific or fresh animal poisons, prevent or retard their decomposition? and thus it is in the parish of St. Marylebone, at least, that for the last three or four years we appear to have a constant supply of scarlet fever poison ready at hand. I am sure our energetic Officer of Health and his subordinates have most assiduously employed, and at no trifling trouble and expense, the various chemicals recommended by the Privy Council; but with what result? *Nil, nil, nil*, or something worse than *nil*, an increase in the number of deaths; and the disease, instead of being epidemic, becoming persistent. As a disinfectant, I have no faith in anything but the fumes of sulphur—sulphurous acid. A little sulphur may be burned in the room of the invalid, half a dozen times a day, without detriment to the patient. As an antiseptic for the sick room, nothing surpasses the fumes of iodine: a few grains placed on a tile and a lighted lamp placed beneath and carried round the room, will remove any septic poison in a few seconds. A little of the tincture of iodine added to water, into which a piece of putrefying meat may be immersed, will at once remove any septic taint; and, after being washed, the meat may be eaten with impunity. I write this from actual experience. I am, etc.,

1, Montagu Square, October 1871.

A. WYNN WILLIAMS, M.D.

## LINIMENTUM POTASSII IODIDI CUM SAPONE.

**SIR**.—The following modification of an old official German formula for the above preparation, may be of use to your correspondent, "A Slowman":—White curd soap (Gibbs), 3 ounces; potassium iodide, 18 drachms; glycerine (1.25 s.g.), 12 fluid-drachms; distilled water, 14 fluid-ounces; oil of lemon, 1½ fluid-drachms; spirits of wine, 1 fluid-ounce. Dissolve the soap with eight ounces of water by gentle heat in a water-bath; dissolve the iodide of potassium and glycerine in the remaining water, and heat the solution to the same temperature as the dissolved soap; mix the solutions, stirring constantly until nearly cold; then add the oil of lemon dissolved in spirit.

It is a semitransparent and gelatinous liniment, somewhat resembling in consistency and appearance "Steer's Opodeldoc." It should be weighed and dispensed in a wide-mouthed bottle or a covered jar. If properly made, it never varies in colour or consistency.

The variable result obtained from the official form are, perhaps, due to the olive oil soap ordered to be used. Olive oil differs greatly in the proportions of oleate and palmitate of glycerine which it contains; and consequently the soaps made therefrom differ in a similar manner.

The samples obtained from wholesale houses were doubtless prepared from private recipes; hence their dissimilarity. I am, etc.,

F. J. BARRETT, Pharmaceutist, South Staffordshire General Hospital.

Wolverhampton, October 9th, 1871.

**SIR**.—In reply to "A Slowman" I beg to state that, for many years, I have been in the habit of adding from half a drachm to one drachm of iodide of potassium to two ounces of the ordinary soap liniment. It is rather slow in dissolving, generally requiring about half an hour; and glycerine may be added or not. I have found it very efficacious in chronic glandular or other swellings, in promoting absorption. I am, etc.,

OCYOR.

## HOUSE-SURGEONS AND FEES FOR NECROPSIES.

**SIR**.—Can you kindly refer me to the law upon which was founded your reply to Dr. Page's question (BRITISH MEDICAL JOURNAL, September 16th, 1871, p. 340) regarding payment to house-surgeons for *post mortem* examinations of patients who die in the house, and oblige Yours faithfully,

WILLIAM HAINING, M.D.

\*. The 5th section of 6 and 7 William IV, c. 89 disentitles the officer of any lunatic asylum, public hospital, or infirmary, from fees for attending inquests on the bodies of persons dying in such infirmaries or hospitals. It does not, of course, disentitle him to fees for inquests on persons brought in dead, and for these cases fees are always paid. So, if in the case of any person dying in a hospital the coroner shall require for his information a *post mortem* examination, this is an extra work, for which the Act requires him to pay an extra fee of a guinea, and he may employ as an expert either the medical officer of the establishment or any other expert. In either case, for this work specially performed by him, he is authorised to pay; and, in case of his declining beforehand to pay the fee, we think the house-surgeon would be justified in requesting him to employ some other expert for the purpose.

**NOTICE TO ADVERTISERS.**—Advertisements should be forwarded direct to the Printing-Office, 37, Great Queen Street, W.C., addressed to Mr. F. H. HEATHCOTE, not later than *Thursday*, twelve o'clock.

#### ACTION OF CHLORAL ON THE FETUS IN UTERO.

**SIR,**—Recently one of my patients, who was within a few days of the expected time of her confinement, was seized with severe pains in the abdomen and back—the result, I think, of cold. I prescribed chloral hydrate in twenty-grain doses every four hours, with benefit. She took two six-ounce mixtures. Labour set in after a few days, and she was confined of a dead child. Is it within the experience of any of your correspondents that chloral hydrate acts injuriously upon the fetus *in utero*?  
I am, etc.,  
AN ASSOCIATE.

**DR. HJALTTELIN (Iceland).**—The paper shall appear next week.

#### PRACTITIONERS AS JURYMEN.

**SIR,**—There is a general impression in our profession that its members are, *virtute officii*, exempt from the annoyance of serving on juries. The enclosed paragraph, extracted from last week's *Malvern Advertiser*, states that—"A question arose as to whether the names of certain medical gentlemen practising in the district, who had not sent in the required claim for exemption, should not be included in the jury list; and Sir Henry Lambert (Chairman, and formerly a barrister) allowed it to be understood that another year that would be done." In the interests of the medical profession, and as a member of it, I solicit your opinion, with any references in support of it in the *JOURNAL*, on the following questions.

1. Are medical men liable to be summoned as jurymen; and, if so, are they obliged to claim exemption previously to the preparation of jury-lists (which should be advertised in the papers, instead of being affixed to a church door, where very few observe the lists)? 2. Is the statement in the paragraph founded on erroneous data?

It cannot be held to be the duty of practitioners to serve as jurymen when the lives, health, and wellbeing of their patients are imperilled.

I am, etc.,  
STANLEY HAYNES, M.D.

Malvern Link, 11th October, 1871.

\* By the 35th section of the Medical Act, "Every person who shall be registered shall be exempt, if he shall so desire, from serving on all juries and inquests whatsoever, and from serving all corporate, parochial, ward, hundred, and township offices, and from serving in the militia; and the name of such person shall not be returned in any list of persons liable to serve in the militia or in any such office as aforesaid." The exemption of registered medical practitioners is, therefore, a matter of law; and they are never called upon individually to claim it. The *Medical Register* shows their claim to exemption, and this is an official document of which copies are furnished by the Government to the various courts.

**MR. CRAISTER (Bramley)** would do well to address the Council of the Royal College of Surgeons on the subject. We are strongly of opinion that this person ought to be struck off the College List and off the Medical Register.

#### THE WEST SOMERSET BRANCH: THE DISCUSSION ON CARBOLIC ACID.

**SIR,**—Practice and recent pathological theory make the above subject one of the most important that can at present engage the inquiry of the profession. As a member present at the meeting on the 3rd instant, when the question "Does application of carbolic acid favour the healing of wounds?" was discussed, my estimation of the verdict was distinctly that, except in one or two presumable cases, carbolic acid should in no form be applied directly to a wound, but that a carbolised outer covering, not in contact with the wound, was found, or (as yet there being no proof) thought to be found, favourable in practice, the theory of its action being questionable; it was certainly not concurred in, that "when used in the dilute form of 1 to 4 or 5 of oil, and 1 to 50 or 100 of water, it exercises a very soothing influence, and is a most valuable aid in the treatment of wounds." Oil doubtless lowers in a greater degree than water the violence of carbolic acid as a penetrating agent; but 1 to 4 or 5 of the former medium, and 1 to 50 or 100 of the latter, are nothing like equivalents; and the meeting did not stultify itself by taxing them to be so. The President's remarks were ingenious, and clearly expressed his conviction that a carbolised atmosphere is destructive of germs, and that germs are a *necesse causa*.  
I am, etc.,  
PROBE.

October 15th, 1871.

**SIR,**—From ill health, after thirty years' service, I have resigned my Poor-law appointments, and have asked for a superannuation pension. If the Board of Guardians grant it, can they prevent my carrying on a small private practice here or elsewhere?  
I am, etc.,  
P. L. O.

\* Certainly not.

#### PAYMENT OF CLUB SUBSCRIPTIONS.

**SIR,**—I have for many years past been the medical officer of the Foresters' Court here at St. Mawes. They have, however, lately used me very severely; and as they will not tender me an apology, I have resigned my appointment. But it seems upon inquiry, that only a certain few have the entire management of affairs, and are, I am afraid, actuated by personal motives. Their term of office expires at the end of the quarter; and at the majority of the court seem disposed to acquiesce in, I have agreed to agree attend them upon the condition that they increase my salary. I have suggested an increase of one shilling per annum for each session and journey. The session used to pay me four shillings, and the summer two shillings per annum. I now require five shillings for the session, and three shillings for the journey, which will then but barely require me for all the attendance, the session, and the journey; and I may be called upon to administer in the course of a year, having but a very small balance for profit, as all medical men must be aware who have anything to do with these societies. I may state that the yearly income of many of the members is less than my own.

As they are so unfriendly to another surgeon, I have felt it but my duty to let the profession know a few matters at hand, and also to ask their support on the present occasion. A gentleman in the neighbourhood of Falmouth has, by misrepresentation, been induced to become their champion for a time; but I am happy to say he has just written me to say that, should I be able to come to my understanding with the court, he will be willing to retire. I could have wished that he had told me so at an earlier period, for he must have been sure that I would not have resigned such a post.

I am, therefore, very anxious to protest against the majority pay of the better class of medical societies in these medical offices; and I shall most certainly look for the support of the whole profession in this most important cause.

St. Mawes, October 15th, 1871.

I am, etc.,  
HENRY HARDEN.

#### ACUPRESSURE.

**SIR,**—In the *BRITISH MEDICAL JOURNAL* of October 7th, I observe a letter by Dr. McRae, of Fettercairn, containing strictures on a recent paper on Acupressure, published elsewhere by Dr. Pirrie. Dr. McRae takes exception to the term "inelastic" as applied to iron wire, and seems to doubt the existence of such a material as elastic iron wire. He would, I think, have done more wisely had he—before adopting the sarcastic tone in which his letter is written—made himself acquainted with the properties of the different varieties of iron wire. It requires no very deep knowledge of the mysteries of hardware to be acquainted with the fact that there is hard tempered iron which is elastic, and annealed wire which is inelastic. Any wire-worker will give Dr. McRae ocular proof of their respective qualities, if he wish to extend his information.

Regarding Dr. McRae's remarks on the origin of the method of acupressure, now called *torsion*, I beg to differ from him; for, though Dr. Knowles did propose it in 1864, Sir J. Y. Simpson had applied it in 1860.

Aberdeen, October 16th, 1871. I am, etc.,  
J. C. OGILVIE WILL, M.D.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The *Whitehaven News*, Oct. 10th; The *Durham Chronicle*, Oct. 20th; The *Carlisle Journal*, Oct. 20th; The *Merthyr Express* and *Advertiser* for the Coal Districts of South Wales, Oct. 21st; The *Sunderland* and *Durham County Herald*, Oct. 20th; *Saunders's News-letter* and *Daily Advertiser*, Oct. 23rd, etc.

#### COMMUNICATIONS, LETTERS, ETC., have been received from:—

Dr. Smart, Penge; Dr. T. Clifford Allbutt, Leeds; Dr. J. D. Heaton, Leeds; Mr. Erichsen, London; Mr. Guest, Manchester; Dr. J. G. Davey, Northwoods, Bristol; Dr. Hitchman, Mickleover; Mr. H. Cooke, Wicklow; Dr. J. Ingleby Mackenzie, Sidmouth; Dr. Althaus, London; Mr. Benson Baker, London; The Secretary of the Pathological Society; Mr. Teevan, London; Mr. W. # REMARKS ON FIBRO-CYSTIC DISEASE OF THE UTERUS.\*

By T. E. BEATTY, M.D., Dublin,

Ex-President of the Royal College of Surgeons and of the King and Queen's College of Physicians in Ireland; President of the Midwifery Section.

THE diagnosis of fibro-cystic disease of the uterus is still a problem unsolved in the history of the diseases of females. Some authors of repute are silent upon the subject, and in most of those that allude to this disease the notices are very short and meagre. In Scanzoni (*Translated by Gardner*, p. 237) we find the subject thus disposed of: "As we have already said, there are fibrous bodies which are formed by the aggregation of tumours of different sizes bound together by loose connecting tissue, which is rich in blood-vessels. In this tissue there are sometimes formed cavernous excavations filled with blood, the rupture of which often occasions very considerable extravasations of blood. At other times this intermediate tissue is infiltrated with serum, and there results therefrom a sort of dropsy of the fibrous body. There are also observations of the formation in the tumour of a cavity more or less large, filled with a serous, sanguineous, or putrid liquid, which, by the constant fluctuation, render during life the diagnosis of a fibrous body very difficult." This is all that is said about this very important subject by Scanzoni.

Dr. Graily Hewitt, in his admirable work on the *Diseases of Women*, takes notice of this affection, speaking of it as "that rare disease." He thus alludes to the improbability of detecting it during life. "The diagnosis of fibro-cystic tumour of the uterus is one of great difficulty, because we have here the two things combined and a solid outgrowth from the uterus which itself contains cysts. The difficulty arises from the physical resemblance this bears to a case of cystic disease of the ovaries. To estimate aright the difficulties of the question, and the best method of surmounting them, careful study of the cases actually published is essential." He goes on, further, to say: "Mr. Spencer Wells mentions two circumstances of assistance in the distinction. One is that the colour of the cyst-wall in fibro-cystic uterine tumours, when laid bare by abdominal incision, is darker than that of ovarian cysts." Now it is rather too late to obtain information after the abdomen has been opened. What we want is to obtain knowledge of signs that will prevent us from cutting into an abdomen by mistake. That such mistakes have been made, and by the ablest observers, is too truly shown in the records of medicine; and to the credit of the profession, it is to be said that there has been no attempt to conceal any of those cases, but, on the contrary, the greatest publicity has been given, and they have been hung out as beacons to warn others from falling into similar mistakes. In the *Biennial Retrospect* for 1865 and 1866, published by the Sydenham Society, I find seven cases alluded to which happened in the hands of Dr. Routh, Mr. Nunneley, Mr. Spencer Wells, Dr. Routh again, Mr. T. Holmes, and Dr. Hilton Fagge, in which gastrotomy was performed in hopes of finding a diseased ovary. In the volume for 1867-68, there is no notice of fibro-cystic disease of the uterus. These do not include the two cases mentioned by Mr. Spencer Wells in the first volume of his *Diseases of the Ovaries*, in the last and most remarkable of which I was implicated, for I had seen the patient before Mr. Spencer Wells, and had given my opinion that it was a case of ovarian dropsy; and at my suggestion the operation was performed. That the disease is a very rare one there can be no doubt, but it is not unlikely that several examples of it may have been treated by tapping, and, finally dying, have been buried as cases of ovarian dropsy, and their nature never ascertained. However, cases are sufficiently numerous to enter into the calculation whenever we come to examine an abdomen containing a fluctuating tumour. But we have not yet arrived at any positive signs by means of which such cases can be detected. Mr. Spencer Wells says (*Diseases of the Ovaries*, vol. i, p. 362): "Given a large semi-solid tumour, fluctuating in some parts, containing cysts which hold upwards of twenty pints of fluid, moving beneath the abdominal wall, the uterus being movable and not enlarged, so far as measure-

ment by the sound can detect, no sound or arterial impulse to be heard which is not often heard in ovarian tumours, and no history of hæmorrhage leading to a suspicion of uterine disease, and it will be admitted that these characters of the two fibro-cystic tumours of the uterus which I removed so closely resemble those of semi-solid ovarian tumours, that diagnosis must be very uncertain."

It fell to my lot to be consulted about one of these cases a short time ago, and I was fortunate enough to make a correct diagnosis, and thus prevent the addition of another to the list of unfortunate operations. The case was under the care of Dr. John Morgan, in Mercer's Hospital, Dublin, and I was invited by him to see and examine the patient. Dr. Morgan has kindly given me permission to make use of the case, and has furnished me with the following particulars.

"M. R., aged 22, married three years, came under my observation on March 15th, 1871. She had been a domestic servant, and always enjoyed good health until about one year after marriage, when she observed rather unexpectedly a small tumour in the left iliac region, which remained of the same size for a year, when she found a similar one commencing in the right iliac fossa. In about three months these growths seemed to have coalesced into one, and had enlarged considerably, giving the appearance of a woman in about the seventh month of pregnancy. She stated that the tumour had rapidly gained this size, and then remained stationary for the last six months. She suffered much from a sensation of weight and bearing down, with a distressing feeling of oppression of the respiration. There was considerable pain in the back and also in the epigastrium, the latter being particularly marked after her admission into hospital. Menstruation had continued rather profusely and at intervals of three weeks. On examination, the abdomen was found to be occupied by a tumour bearing great resemblance in every way to an ovarian dropsy. It was dull on percussion, was of an oval outline, uniform to the feel, and deep fluctuation could be perceived. In order to test fully the nature of the tumour, I tapped it on the left side with a small-sized trocar tube of the *aspirateur* on March 23rd, and I removed twelve or fourteen ounces of a dark-coloured fluid nearly of the colour of beer, of rather viscid consistence, and highly albuminous. As the patient fancied herself relieved by this procedure, I tapped her again on March 30th with the *aspirateur* trocar, and removed about the same quantity of fluid. The trocar was introduced about three inches lower down than on the first occasion. Neither of these operations was followed by any untoward symptom. She now underwent a rather profuse menstrual period of eight days' duration, after which, as the case was one of difficulty, I requested the assistance of Dr. Beatty, who, in company with Dr. Atthill, kindly examined the case. In some days afterwards, Dr. Churchill saw the patient, and on the same day I tapped the tumour on the opposite side with the *aspirateur* trocar, and withdrew nearly three pints of the same kind of coloured viscid fluid. During the succeeding twenty-four hours, symptoms of peritoneal inflammation showed themselves. She became collapsed, constant greenish vomiting came on, and she died on May 7th, 1871."

*Post Mortem Examination.*—The body generally was in good condition; the abdomen was much distended by gas. There was a considerable amount of purulent matter in the cavity of the abdomen and around the tumour. There were some adhesions between the omentum and the tumour, and in three places these were tolerably firm. The surface of the tumour was uniform, and from the upper part a curious offset had grown, which had apparently given way and caused the peritonitis. There was no evidence of inflammation in the vicinity of the punctures. On raising the tumour, the ovaries were found in their normal position, and free from disease. The tumour was found to have grown from the upper part of the fundus uteri. The large cyst in immediate connection with the uterus was opened, and showed the remarkable figure of the interior.

When I examined the woman, the tumour in the abdomen resembled in size and shape the gravid uterus between the seventh and eighth month. There was evident fluctuation, and it seemed as if the fluid was in one large chamber, but the walls of the cavity felt thicker under the fingers than is the case in a single cyst of ovarian dropsy. There was a doughy feel when pressed deeply, as if thick flesh formed the walls of the cavity, and the tumour could be traced deep down into the pelvis. On examination *per vaginam*, the os and cervix uteri were found in a natural condition, and the sound passed in gave evidence of the normal size of the organ; but it was fixed, and would not be moved in any direction. The length of time the tumour had taken to arrive at its present development was well considered. This is an element observed upon by Dr. Graily Hewitt in his work on the *Diseases of Women*. He considers it as a diagnostic mark between uterine and ovarian tumours, the growth being lower in the uterine than in the ovarian cases. I was fortunate in the case with which I

\* Read in the Midwifery Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

had to deal, for it was not of great size like that one in which Mr. Spencer Wells had operated at my suggestion (the girth of which was fifty-six inches); but the walls, instead of being spread out and thinned by distension, had still a considerable amount of thickness, which gave the peculiar doughy feel to the fingers, while the cavity was still so large as to give a very distinct fluctuation. This symptom, though available to me on this occasion, would not be of equal value in a case wherein the walls had become thin by distension, and therefore I do not offer it as a diagnostic mark in all cases of fibro-cystic disease of the uterus, but I think it would be useful in those that had not attained a great magnitude. The profuse and repeated occurrence of menorrhagia suggested the existence of fibroids, and the fixity of the uterus, though natural in size and shape, showed that it was attached intimately to something above it, and that being a soft, fleshy-feeling, doughy tumour with fluctuation, led me to the conclusion that the case was one of fibro-cystic disease of the uterus, an opinion which I then communicated to Dr. Morgan. I have much pleasure in being able, through the kindness of Dr. Morgan and Dr. John Barker, the Curator of the Museum of the Royal College of Surgeons in Ireland, to exhibit the specimen and the cast of the tumour, taken before it was opened. The length, including the uterus, from which it grew, was 14½ inches; the circumference at the middle was 25½ inches. The tumour grew from the upper surface of the uterus, which up to that point is perfectly natural and healthy. On slitting up the uterus, the interior was found in a normal condition, and a very perfect *arbor vite uterine* occupied the canal of the cervix. The tumour, on being cut open, displayed the large irregular rough cavity which you see; and this extended into the small projection from the upper part of its periphery. The ovaries are both healthy. The urinary bladder is shown *in situ* with a close adhesion to the tumour.

I think it is a misnomer to call this a cystic disease; for, in point of fact, there is no proper cyst in it. There is no lining membrane to the irregularly shaped cavern, at least in its progressive stage, as this specimen is; but the chamber seems to be composed of a number of cavities, all thrown into one or more large ones, with rough irregular folds of fleshy fibrous material hanging into it on all sides. It appears that Scanzoni's description of the origin and formation of the disease is correct. Speaking of the composition of fibrous tumours, he says: "In this tissue there are sometimes formed cavernous excavations filled with blood, the rupture of which often occasions very considerable extravasations of blood. At other times, this intermediate tissue is infiltrated with serum, and there results therefrom a sort of dropsy of the fibrous body. There are also observations of the formation in the tumour of a cavity more or less large, filled with a serous, sanguineous, or putrid liquid, which, by the constant fluctuation, render during life the diagnosis of a fibrous body very difficult."

As examples of this disease are very rare, I have thought it right to produce this specimen at this meeting of the British Medical Association, as a caution to all who investigate tumours in the abdomen.

Since writing the above, I have read the case of fibrous tumour of the uterus, removed from the uterus by Mr. Spencer Wells by means of gastrotomy and the *éclateur*, published in the *Medical Times and Gazette* of July 29th, 1871. That most remarkable case recovered after many struggles, and is the first of its kind in these kingdoms. It will, no doubt, give fresh courage to operators; and in the case just detailed it might have been imitated, for the connexion between the uterus and tumour could have been easily cut through by the *éclateur*.

#### ABDOMINAL PUNCTURE IN TYMPANITES.

IN the JOURNAL for October 21st, page 464, Mr. J. H. Wathen mentions that the earliest case of the use of "Puncture of the Colon for the Relief of Tympanites" which he has discovered, was by Mr. Teale, in February 1869.

I find the following remarks in the late Mr. T. P. Teale's Address on Surgery at Sheffield, in July 1845, at page 119 (*Transactions of the Provincial Medical and Surgical Association*: new series, vol. ii, 1846).

"*Paracentesis of the Intestine for Tympanites*.—The practice of paracentesis of the abdomen has been lately adopted by Sir Henry Marsh, for the relief of excessive distension of the abdomen from flatus, with the most soothing effect, and without any injurious consequences. The operation was performed with a fine trocar, and repeated several times, with great relief to the patient. M. Levret has also adopted the same practice. After evacuation of the air, immediate relief was obtained, and the patient rapidly recovered."

It may be further added that this mode of treatment also received the high sanction of Sir Philip Crampton and Mr. Cusack twenty-seven years ago.

## ABSTRACT OF A CLINICAL LECTURE

ON A

### CASE OF SEVERE INJURY TO THE LOWER END OF THE FEMUR.

By PRESCOTT HEWETT, Esq., F.R.C.S.,

Surgeon to St. George's Hospital, etc.

GENTLEMEN,—The subject which I bring before your notice to-day is one of great interest, and one which may be to you, by-and-bye, in practice of the utmost importance, and which might, in some measure, affect your reputation: I allude to the case of the girl in the Wellington Ward, in the third or fourth bed on the right. She was admitted into the hospital on the 21st September last, and, as it is now the 17th of October, she has been a month in the hospital. She was walking down a flight of stairs at the International Exhibition, and, while doing so, she caught her foot on the edge of a step and fell, sustaining, it was supposed, a fracture of the end of the femur. She wore high-heeled boots. I do not know how it has happened, but there have been a great many accidents in the International Exhibition. I suppose they must have arisen partly from the height of the stairs, and partly from the height of the ladies' heels. Ladies are anxious to look tall, thinking that their appearance is improved, and therefore they wear high-heeled boots. Such accidents are not always, however, due to the high heels, for a lady whom I knew fell by tripping on the stairs at the Exhibition, and came down on the cheek-bone, breaking it, and having ecchymosis on the right side of the face for months afterwards. But the first thing to which I would call your attention in this case is the high heels of the boots. Ladies will, for the most part, wear them; but they could not do a worse thing, for their feet are placed in a difficult and most unnatural position. They are very tenacious about this fashion, but you must be as tenacious against it: the number of accidents in consequence is very great. To show you how very tenacious ladies are on this point, last year I was sent for to see a young lady in one of our London hotels. She wished to consult me about her foot. On seeing it, I thought its state depended upon her boots, and I asked to see them. The boots were brought in by the lady's maid, but the only thing I could observe about them was an immensely high heel. I said: "It is the high heel of your boots that causes the mischief, and unless you diminish this I can do nothing for you." She became quite angry, and said she could not alter them. "I cannot do it, and I will not." Suddenly again she toned down, and said: "Pray, sir, what would people say if they saw me walking about the park without high heels?" I said: "It is simply heels *versus* brains. If you have brains, you will cut off the heels; if you have no brains, you will continue to wear them." She fortunately had brains, cut off the heels, and her foot got quite well.

To return to our patient. On admission to the hospital, this girl was, as I said, supposed to have a fracture of the lower end of the femur, close to the joint, and the injury was all but compound. A long splint was applied, but it was very difficult to keep the fragments in their proper place; and, as the surrounding parts became very swollen and painful, the patient was put on an Earle's bedstead on the 26th, and then matters went on until I returned from my holiday, when I took charge of my patients on the 2nd of October, and saw this girl, being told there was great difficulty in keeping the fragments in their proper position. On examining the leg, after taking off the short splints, I found that there was a large projection on the outside of the thigh-bone, due to the upper piece of the bone pressing against the skin. And now, a closer examination of the parts led me to think that, after all, the case was perhaps one of separation of the epiphysis, and not a fracture. The injury is close to the knee-joint. The bone projecting is certainly not more than an inch above the condyle; the fragment, instead of being sharp, is obtuse; in addition to which we have the age of the girl, 17, and the nature of the accident. This case is then, I think, one of separation of the epiphysis of the femur.

Severe injuries to the lower end of the femur may be of two kinds—a fracture close to the knee-joint, and a separation of the epiphysis; the former is by far the more common form of the injury—the latter being, indeed, rarely met with in adults. It is but a few years ago that we were first quite clear as to what happens in the separation of the epiphyses, and all the cases published then were cases of children. I presume that you know we have a line of cartilage at the lower epiphysis of the femur. So long as this exists, so long may a separation take place. The question then arises, At what time of life does this piece of cartilage disappear and the condyles become joined to the shaft? The age varies in different individuals. The cartilage sometimes exists up to the age of 25 years. You will find in most of the authors no allusion

made to the possibility of this accident from 18 to 25 : it is only mentioned in a very casual manner that this does not take place after 14 or 16. However, I have had several cases at a later age than that. (Here Mr. Hewett showed a specimen in which there was a separation of the epiphysis at the age of 18.) You see the condyle completely torn off : it happened when I was assistant-surgeon. You will find a very accurate history of this case in the Catalogue of our Museum, vol. i, p. 137. There was also in this case a separation of the epiphysis of the tibia and lower end of the fibula. The limb, from the knee downwards, was icy cold, and there was great swelling about the ankle. Mr. Caesar Hawkins, under whose care the patient was, amputated the thigh. On dissecting the knee-joint, all the deformity was found to depend upon a separation of the epiphysis, and the coldness of the joint upon an injury to the popliteal artery. The case in the hospital now reminds me very strongly of Mr. Hawkins's case. Now this case is one which might in a country village lead you into great trouble. You may depend upon it that, if such a case as this unluckily fell into your hands when you were beginning practice, it would be said that you did not know your business or you could make it all right. In a separation of the epiphysis what happens is this : the cartilage is torn from the bone in some parts, and in others the bone itself gives way, so that there is a very irregular jagged surface. To readapt such surface is a very difficult matter. You may bring one part into the proper place but not another, and such is the case with this girl. If a dissection were made, you would probably find such to be the condition of the parts.

I have shown you a specimen of separation of the epiphysis from our museum at 18 years of age. There is another such at 17, and two at 16, and all these histories are fully detailed in the Catalogue ; and there might be separation of the epiphysis at a later age even than 18. Always bear in mind that such may possibly happen, but very rarely, it is true, till the age of 25.

[Mr. Hewett then dwelt on fracture properly so called of the lower end of the femur, narrating some interesting cases, and exhibiting a number of specimens involving the condyles from the museum. He then proceeded.]

Having made out what is the nature of the accident in this girl, I must make some mention of the plan of treatment. In the present day, we for the most part use the long splint in cases of fracture about the lower end of the femur. When this girl came in, the long splint was applied ; but Mr. Rouse, after two or three days' trial with this splint, resorted to the inclined plane. The first was Earle's bedstead ; and then, finding that this did not answer, I ordered a common inclined plane, since which the parts have been kept in much better apposition, and she now finds herself much more comfortable. In addition to the inclined plane on which the limb rests, we have short splints on the outer, inner, and upper parts. I have been very careful to tell the girl that she will have some deformity about the thigh, although it will not interfere with her walking. And when you have a case of this kind to deal with, gentlemen, and you see that there must be some deformity, you will find it wisest to tell your patient and friends that such must be the case.

#### SMALL-POX IMPORTED INTO ICELAND BY FRENCH FISHING VESSELS, STAMPED OUT BY QUARANTINE AND SULPHUROUS FUMIGATIONS.

By J. HJALTELIN, M.D.,

Chevalier of the Legion of Honour ; Knight of the Order Dannebrog, etc. ;  
Chief Physician in Iceland.

In the middle of April last, four French fishing vessels came into the harbour of Reykjavik, in order to ask for medical aid against small-pox, which was then believed to be very common in the French fishing fleet all round the southern shores of our island. The first vessels that came into our harbour were from St. Valéry-en-Coutte, where a small-pox epidemic was said to be extremely malignant at that time. One of these vessels had five sick men on board, three of whom had confluent variola ; and one sailor had died of the same disease before they arrived here, but had of course been buried in the ocean.

The sudden appearance of a malignant and highly contagious epidemic on our coast, and the news from abroad of the ravages of small-pox both in France and in England and Germany, excited great fear amongst the inhabitants, and that fear was fostered by the arrival of more vessels with new cases.\*

Vaccination and revaccination were immediately instituted, with as much speed as was possible, throughout the whole country ; and I gave orders to all our medical men and the ordinary vaccinators to set to work without delay, and they were to that end provided with fresh vaccine-lymph and vaccine-crusts.

In order to try to prevent this dangerous disease from spreading, I advised our government to have at once a quarantine-hospital erected—of course not in our small town itself, but in its neighbourhood. An old large house, situated about half an English mile from the town, and which some years since had been the seat of our bishop, was as soon as possible fitted out for this purpose, and the vessels were ordered to bring their patients to this place, in their own boats, under the control of our policemen. The hospital was fitted with beds and some necessary furniture ; a medical student with some servants were lodged in it, and they were strictly prohibited from having any intercourse or communication with people outside.

I myself was obliged to visit this hospital daily, in order to look at the patients, prescribe the necessary medicines, and direct what else might be needful. I found most of the sailors very seriously ill, and no fewer than seven of them had the confluent small-pox ; they were evidently in great danger. Some sailors who were on board one vessel would not be carried into the hospital, but preferred to remain on board their own boat, prepared to live or die, as the chance might happen. I treated them on board the vessel itself, and when they seemed a little better they went home to their native country. These patients were treated in the same manner as those in the hospital. Most of the crew on board this vessel had evident marks of having, lately or before they sailed for Iceland, been affected with small-pox.

As this serious epidemic showed a high degree of malignity, and it could scarcely be hoped that the quarantine regulations would be sufficient to save the inhabitants from the disease, I considered what would be the best means to prevent it and to treat it. As I am a firm believer in the power of disinfectant and antiseptic remedies, I could not long hesitate in my plan, but was resolved to try these remedies one after another. The chief question appeared to be, whether I should use the oxygenating or the disoxygenating compounds of this class ; but for some reasons I thought that the disoxygenating antiseptics would be the most safe. I knew very well that some German physicians had in former days tried chlorine water with considerable success against malignant small-pox ; but, as I thought that remedy rather too irritant for the respiratory organs, I determined to try sulphurous acid, both externally and internally—externally in the form of fumigation, by burning refined sulphur in the sick rooms ; and internally by giving sulphurous acid mixed with pure water. The effect was very highly encouraging ; and it soon became evident that, although the patients at first had a great aversion to the fumigation, and complained of the strong and pungent sulphurous odour, they soon felt the good effects of it ; and they became so eager for it that I was obliged to restrain their eagerness a little, being afraid that their lungs might suffer. At the same time they got ordinary sulphurous acid internally, mixed only with pure water—the usual dose being about a drachm, mixed with an ounce of water, and this being taken every third hour. The result of this treatment was very satisfactory, for not only did the eruptive fever and the heat diminish, but in the milder form of the disease the vesicles dried very quickly, leaving the skin covered with thin brown scales, which soon fell off. Out of twenty-two patients treated in this way, I only lost one : he was brought to the hospital in a moribund state, and expired about thirty-nine hours after his arrival. Amongst the patients thus treated, seven had confluent small-pox ; and of these, three were in the fourth or suppurative stage when they came into the hospital, and four were in the third stage. The others had the variola discreta in a high degree, with all the common symptoms of small-pox ; namely, high fever, with distinct minute papule, elevated above the surface, always beginning in the face at the side of the nose, and thence extending over the whole face, and lastly over the trunk and the extremities. In such cases the vesicles were very numerous, although not confluent ; and there were more or less severe headache, hoarseness, difficulty of swallowing, and some pytalism. These were generally quickly cured, and many of the patients could leave their beds after a few days ; they were then allowed to walk about, and some of them were even desirous after twelve days to go on board their fishing vessels.

Those with the confluent small-pox had of course more severe symptoms, and their cure required, therefore, a longer time. Some of them became blind in the suppurative stage, and the swelling of their faces was enormous : the secondary fever was, nevertheless, not so serious as

\* Captain Timbre, the Commander of the French Squadron stationed here, thought that the matter looked rather serious ; for, on account of his report, a large ambulance steamer was fitted out by the French Government. This steamer, however, arrived here in June, when all was over. It had on board four physicians and

two apothecaries ; and was intended equally for the benefit of the Icelanders and of the French fishing fleet, in case of need. This is one of the many instances of the noble feelings of the high-minded French nation ; for sure it is, that assistance would have been necessary, if the epidemic had not been stamped out in time.

might have been expected, and all, except one who died, were quite cured in the course of five weeks, without any other bad consequences than that most of them were deeply pitted in their faces. Nearly all of them had secondary abscesses both on the trunk and the extremities; but these, after having been opened, healed in a short time without any ill results. In order to protect the sight, I used nitrate of silver, which I thought more sure than collodion.

The tension of the skin was very much relieved by the external use of linseed-oil, mixed with one-fifth part of carbolic acid, rubbed into the surface with a soft brush. Bed-sores and secondary abscesses were treated in the same manner.

Besides the generally favourable results of this treatment, there were also some remarkable circumstances which convinced me of the good effect produced by the sulphurous acid. These may be thus summed up in a few words.

1. The use of the sulphurous acid fumigation and the sulphurous acid internally evidently mitigated the primary and secondary fevers; the heat of the body was remarkably lowered, and the thirst was quenched even when the primary and secondary fevers ran very high.

2. The symptoms generally following the primary and secondary fevers of small-pox—as the pains in the back and the articulations, severe headache, vomiting, pyalism, etc.—were evidently mitigated by the internal use of the sulphurous acid; and I feel, moreover, inclined to believe that the sulphurous fumigations, which, to tell the truth, were used in an uncommon strength in all the rooms, probably assisted the internal use of the sulphurous acid in no slight degree.

3. There were, moreover, some facts which at least seemed to make it highly probable that the sulphurous acid and the sulphurous fumigations have a really destructive power on the small-pox virus. Of instances pointing in that direction I will cite a few.

When the quarantine hospital was being fitted out, the house-surgeon and the servants were all immediately revaccinated; and this revaccination had, at least in two of them, already produced true vaccine vesicles when they were shut up in the quarantine hospital. No sooner, however, had they been exposed to the sulphurous fumigations than the vesicles dried away without any following suppuration, just as the small-pox vesicles were afterwards seen to do on other patients who, before the beginning of the suppurative stage, arrived at the hospital. One other fact is perhaps more striking than all: a carpenter had been taken into the quarantine in order to make some new beds for the patients, and remained there among the sick for some time. When he had done his work he was let out, after having been exposed to strong sulphurous fumigations. He was then outside under strict observation during fourteen days; and when no precursory symptoms could be observed in him he was revaccinated with complete success, and had true vaccine pits a second time, for he had been vaccinated twenty years before.

But be all this as it may—and every one may explain these facts as he likes—at all events so much is certain, that a malignant small-pox has been successfully treated and stamped out of this island in the aforesaid manner, without having infected a single person of its inhabitants. This is a fact which cannot be denied, and facts are, as we all know, “stubborn things”. There was certainly an extensive focus for contagion; and it is seldom the case that quarantine regulations are sufficient to destroy a disease of such tenacity and frightful virus as that of malignant small-pox. Experience has, on the other hand, shown that the Icelanders are, no less than other people of the globe, extremely liable to the small-pox contagion. In the past century the small-pox was very often imported into this island, and every Iclander is still shocked when he reads of the frightful epidemic of that kind which, in 1707, killed one-fourth part, or 18,000, of the inhabitants. Even in this century—viz., in 1840, small-pox was imported here; and in one parish where vaccination had been neglected it destroyed no less than one-eighth of the people, leaving others blind and lame, or very much disfigured. These instances are, amongst many others, a great warning against the erroneous and dangerous doctrines of the “antivaccine” apostles, who even in this *ultima Thule* are preaching their baneful and stupid dogmas.

The neglect of vaccination was clear enough in all the French sailors who came into our quarantine. Among the seven affected with confluent variola, I could not detect any true vaccine marks on their arms, although they told me that they had been vaccinated in their younger days.

As to the action of the sulphurous fumigation and the sulphurous acid, I must still make the following remarks. As generally known, it is commonly believed that the fumes of sulphurous acid are poisonous, and we therefore still find them in Dr. Alfred Taylor's *Medical Jurisprudence* characterised in this way: “The sulphurous acid gas, when existing in a very small proportion in air, has the power of irritating the glottis so violently that, if accidentally respired, it would commonly compel

the individual to leave the spot before the vapours were sufficiently concentrated to destroy life.” But sure it is that, although this gas is very irritant to all those who are not accustomed to it, I feel from experience convinced that it may be respired to a far higher degree than has hitherto been commonly believed; and I therefore fully agree with Naquet, who (in his *Modern Chemistry*, translated by Wm. Cortis, p. 114) says: “Sulphurous anhydride has a pungent odour; it excites coughing, but is not dangerous, unless it form a large proportion of the atmosphere.” I feel convinced that patients may be accustomed to it to a high degree, without any bad effect, and I therefore regard it as far less dangerous or inconvenient than chlorine gas. I have, moreover, remarked that sulphurous acid gas may even be inhaled with benefit in bronchial affections, and it has often been remarked here, during severe influenza or epidemic catarrh, that the sulphur diggers at the sulphur mines at Krisuvik have been quite free from that epidemic. At the quarantine I remarked the same fact; and while an epidemic catarrh was very common, both in Reykjavik and all round in its neighbourhood, all the people in the quarantine were exempt from it. The great disoxydising effects of sulphurous acid cannot be denied, and its cooling effect upon the system may easily be demonstrated; its destructive effects upon parasitic life are likewise undeniable; and why should it not also be capable of destroying “microzymes”? I have fully tried its beneficial effect in typhus and enteric fever, and I have no doubt of its usefulness in many other zymotic diseases. But, alas! our modern medical science seems still to have a very small and limited faith in real chemical physics; most is left to the so-called “healing act” of nature; it is trusted to flesh and blood to destroy zymotic poisons, as though the inventions of the human mind would never be able to master them, and therefore we still read in some journals, and indeed in some medical works of standing, that even such dangerous poisons as the variola virus should be left to the curative effect of the system itself.

One very eminent and highly esteemed medical author, Dr. W. Aitken, speaking of the treatment of confluent small-pox, says in his *Science and Practice of Medicine* (London, 1866, vol. i, page 260): “Small-pox must run its course, for it is not under the influence of any specific;” and another, Dr. Hermann Lebert of Berlin, in his *Handbuch der Practischen Medizin* (Tubingen, 1863, vol. i, page 71), writes to the effect that he has found it sufficient, even in confluent small-pox, to keep the patient in a moderate temperature, and give cooling medicines. But it must be remarked that both those authorities reckon the mortality from confluent small-pox at from 35 to 50 per cent.

Nearly ten years since I wrote in the *Edinburgh Medical Journal* my humble opinions about the disinfectant treatment of typhus, which I then thought might be extended to some, or perhaps most, other zymotic diseases. Time has confirmed in me the opinions which I then expressed, and has, moreover, convinced me of the worthlessness and danger of the so-called “expectant treatment” in all cases of malignant epidemics.

Reykjavik, October 10th, 1871.

## EXFOLIATION OF THE BLADDER.

By GEORGE BUCHANAN, A.M., M.D.,

Surgeon and Lecturer on Clinical Surgery, Royal Infirmary, Glasgow, etc.

MY attention having been directed to this subject by reading a paper in the *BRITISH MEDICAL JOURNAL* for October 14th, I think the record of the following case occurring in the male, may prove interesting, as an addition to the important series of cases recently recorded in the *JOURNAL*.

Mr. C., aged about 60, a tall gentleman, of spare habit and sallow complexion, was placed under my surgical treatment by Dr. J. G. Wilson, his family medical attendant.

Dr. Wilson informed me that for several years Mr. C. had been in the habit of consulting him for dyspepsia, accompanied by rather vague urinary symptoms, the passing of urine being sometimes attended with pain. Both ailments were from time to time mitigated by the use of the water of some of the German spas, to which he was annually in the habit of resorting. Last year the continental war prevented his annual visit, and to that, along with anxiety as to some of his relatives who were engaged with the armies in the field, he attributed his being worse than usual last winter.

When I saw him, on December 20th, I found him suffering from cystorrhoea, the urine when cooled being loaded withropy mucus and clouded with phosphatic deposit. The calls to pass urine were very frequent, obliging him to rise almost every hour during the night, and there were both pain and difficulty in micturition. On examination with a bougie,

I found a contraction at the membranous portion of the urethra; but that it was simply spasmodic, seemed probable from the fact that it had become occasionally spontaneously improved. With a little care I managed to pass a No. 5 silver catheter without pain, but after it was introduced it was firmly grasped by the urethra. Next day the spasm was nearly gone, and the urethra easily admitted an instrument of moderate size. The passage of bougies was continued daily till all tendency to contraction seemed removed, and the symptoms abated somewhat. Triticum repens in infusion was used for many weeks, without much influence on the appearance of the urine. Subsequently, I tried the effect of washing the bladder every two or three days with astringents, with some temporary benefit, but without any decided result. In the spring Mr. C. went into the country for a few weeks, and returned improved in general health, but with all the urinary symptoms much the same as when I desisted from active treatment. He then went abroad to try once more the effect of some of the German waters.

In September last, in the course of a continental holiday, I visited Baden Baden, and happened to meet my patient, Mr. C. I was surprised to find him very much improved in every way, the urinary symptoms having entirely disappeared, so that he now enjoyed a refreshing sleep during the night without requiring to rise; and that he was free from any uneasiness was obvious to me, for he was two or three hours with me taking his ice, and listening to the music in front of the Kursaal. On questioning him as to how this came about, he informed me that he had been to Wildbad, where he had taken a course of water and baths. But the crisis of his complaint happened when one day he felt unusual difficulty in passing urine, and, after considerable effort, expelled a white membranous substance, which he described as being like a little bag just of the size of the bladder. This he preserved, and shewed to his medical man, who declared it to be an exfoliation of the mucous membrane of the bladder expelled entire.

Since the discharge of this membranous cast of the bladder Mr. C. has had neither difficulty nor pain in micturition; the urine remains free from mucus and sediment; in fact, all the symptoms of cystorrhœa have disappeared.

## ON INTEMPERANCE AS A CAUSE OF CHRONIC BRIGHT'S DISEASE.\*

By WILLIAM ROBERTS, M.D., F.R.C.P.,

Physician to the Manchester Royal Infirmary.

DR. DICKINSON, in his recent able work on *Albuminuria*, has called in question the generally received opinion that the abuse of ardent spirits is, either alone or as reinforcing other etiological conditions, one of the most important causes of chronic Bright's disease. In an elaborate chapter he adduces a considerable array of statements and figures which have led him to the conclusion that, setting aside the cases associated with gout, alcohol has but a slight and remote effect in producing degeneration of the kidneys. This opinion, coming from such a quarter, and apparently supported strongly by facts, is likely to have a considerable influence on the minds of the next generation of practitioners, and, if it be an unsound opinion, is sure to lead to serious mischief in practice. This is the reason why I have considered it desirable to examine the evidence on which this opinion is grounded, and to bring the results of my inquiries under the notice of the Section.

The evidence hitherto relied on by writers on renal disease, in proof of the evil effects of alcohol on the kidneys, is of the same kind as that which is held sufficient to establish the connexion between intemperance and cirrhosis of the liver—namely, the fact that a large number of drunkards and intemperate persons are found among the subjects of chronic Bright's disease. Not only has this connexion been recognised by all writers on Bright's disease in this country and America, where intemperance is rife, but even in Germany and France, where the vice, at least in the form of spirit-drinking, is less prevalent than with us. The morbus Brightii of drunkards is a well understood type of disease among German writers. The impression that has grown on my own mind from an experience of several years both in public and private practice—much of which has been among patients suffering from renal disorders—is very strong that the intemperate, if they escape the earlier perils of delirium tremens, cirrhosis, and alcoholic phthisis, fall victims in large numbers, in their later years, to renal degeneration.

My present purpose, however, is not to set forth the facts which support the old opinion, but to show the inadequacy of the arguments brought forward by Dr. Dickinson in support of the contrary and new one.

The first kind of evidence adduced by Dr. Dickinson is based on the results of *post mortem* examinations of persons who had died of delirium tremens, or of individuals who, having been notorious drunkards, met with a violent death.

From the records of St. George's Hospital, he obtained the details of the *post mortem* examinations of fifty-two adult males who had died of delirium tremens. From the same sources he took, for comparison, the same number of examinations of adult males who had met with accidental death, excluding such as had been notoriously drunken. The state of the kidneys in these two sets of cases is shown in the following table.

	Delirium tremens (average age, 38).	Accident (average age, 41).
Natural .....	28	32
Congested .....	14	5
Slight or uncertain changes in the cortex ..	3	1
Large, smooth, mottled .....	3	1
Granular surfaces .....	3	6
Cysts, without other changes .....	1	7

The first thing that strikes one in examining this table is, not the slightness of the alterations in the delirium tremens cases, but the enormous proportion of serious organic disease in the accident cases. Is it to be believed that one in every seven or eight presumably healthy persons of the average age of 41 is the subject of granular kidney, or of the large smooth mottled kidney? This point alone would seem sufficient to fatally vitiate these observations. If the delirium tremens cases be taken by themselves, they present a sufficiently strong indication of the evil effects of alcohol on the kidneys. In nine cases, serious changes, either advanced or incipient, existed in the kidneys; in fourteen cases, there was congestion; and a perfectly natural state existed only in a little more than one-half. It is to be borne in mind that renal degeneration is usually a late event in the life of the intemperate; and that, consequently, the signs of renal disease in those who die at an average age of 41 might be expected to be found, for the most part, only in an incipient stage.

Dr. Dickinson next refers to the papers of Dr. Ogston of Aberdeen, who has minutely recorded the *post mortem* appearances of a chronic kind met with in the bodies—first, of seventy-three persons who were notoriously intemperate, and who had perished suddenly from the effects of accident, suicide, or homicide, and while apparently in ordinary health and activity; and, secondly, of forty-four additional persons of the same habits, who had also perished suddenly while apparently in ordinary health, but whose death was more directly traceable to the abuse of stimuli. The changes found in the kidneys are thus tabulated by Dr. Ogston.

### First Series—73 cases, average age about 43 years.

General fatty degeneration in 1 case.

Hyperæmia in 4 cases.

Hypertrophy in 13 cases (in 5, lobulated; in 2, the cortices pale and attenuated; in 2, with yellow patches of fatty degeneration over the cortices; in 1, with partial obliteration of the tubuli; in 2, with granular surfaces; in 1, with (12) pus-dépôts in one kidney; coincidently in 1, with albuminous urine).

Atrophy in 1 case (kidneys attenuated, pale, with yellow fatty deposits in their cortices, serous cysts on their surfaces, and albuminous urine).

Buff-coloured, and cortices attenuated, in 4 cases (in 2, with albuminous urine).

Abnormal appearances in the kidneys, in all, in 23 cases, or in 31.5 per cent of the whole.

### Second Series—44 cases, average age about 48 years.

Extensive fatty degeneration in 6 cases (surfaces granular in 3).

Hyperæmia in 9 cases (with albuminous urine in 1).

Hypertrophy in 14 cases (in 2, confined to the right kidney; in 2, kidneys lobulated; in 2, cortices pale and attenuated; in 1, tubuli obliterated; in 3, extensive fatty degeneration; in 4, marked hyperæmia; in 3, substance softened; in 2, atrophy of the left kidney; in 2, albuminous urine).

General atrophy in 3 cases (both kidneys in 1, right kidney in 1, left kidney in 1).

Partial atrophy in 6 cases (tubuli wasted in 2, cortices in 4).

Partial fatty degeneration in 5 cases (tubuli wasted in 1, surfaces granular in 1, cortices attenuated in 1, albuminous urine in 2).

Abnormal appearances in the kidneys, in all, in 28 cases, or in 63.6 per cent of the whole.

I am at a loss to understand how Dr. Dickinson could study these

\* Read before the Medical Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

ables without coming to the conclusion that the abuse of alcohol is a powerful agent in inducing renal degeneration. Whether regard be had to the gravity of the changes recorded, or to the percentage of cases in which they were found, the evidence of these tables seems altogether unequivocal. In judging them, Dr. Dickinson seems to have been unconsciously biased by his individual views of the types of renal disease, and to have overlooked the fact that clinically these types, speaking of chronic cases, are in large numbers, if not in the majority of cases, mixed together so as to produce a composite anatomical state. It must also be remembered that the alterations here recorded occurred in the bodies of persons who perished suddenly, while apparently in the enjoyment of their ordinary health; and that, consequently, they might be expected to be, for the most part, only in an early stage of development.

Dr. Dickinson next refers to the paper of Dr. Peters of New York, who examined the bodies of nearly seventy persons who had died from the excessive use of ardent spirits. Dr. Peters thus describes the changes found in the kidneys: "The kidneys are generally somewhat enlarged, flabby, their cortical substances infiltrated in numerous small spots, with a whitish matter, either albuminous or fatty; occasionally they are granular." This description is too vague to found any argument upon; but it seems to indicate a not inconsiderable amount of disease. Dr. Dickinson remarks on the granular condition having been only found *occasionally*; but I find in the same paper that "granular liver was found in four or five cases only"; so that in that respect the kidneys and liver were not very differently situated.

In the last place, Dr. Dickinson appeals to the Reports of the Registrar-General, and founds an apparently cogent argument on the want of correspondence between the death-rate from Bright's disease and the degree of intemperance prevailing in different localities. I have carefully gone over this point, taking the proportional number of deaths entered under the headings Delirium Tremens and Intemperance as a gauge of the inebriety or sobriety of the contrasted localities, and comparing large numbers, or a series of years, in order to get at tolerably trustworthy averages. My surprise was great to find that the conclusion of Dr. Dickinson was substantially correct, and that the death-rate from Bright's disease was as high in the more sober districts as in the more intemperate districts, and frequently much higher. But my surprise was still increased when I found that the death-rate from diseases of the liver, and from those specially entered as hepatitis or cirrhosis, was no higher—often much lower—in the more drunken districts than in the more sober districts. Now there is nothing more certain in the whole range of etiology than that diseases of the liver, and especially cirrhosis, are produced by the abuse of ardent spirits; and yet the Registrar-General's Reports show no trace of this connexion; indeed, if they show anything, they show that intemperance is actually a protection against diseases of the liver. This is a manifest *reductio ad absurdum* of this part of Dr. Dickinson's argument.

The following table summarises some of the results which justify the above observations.

*Comparison of the Proportional Number of Deaths from Intemperance, from Diseases of the Kidney, and from Diseases of the Liver, in different Districts.*

	Deaths from intemperance.	Deaths from renal disease.	Deaths from liver-disease.
Town districts of Scotland, for the ten years 1855-64 . . . . .	1 in 402.	1 in 134.	1 in 105.
Mainland rural districts of Scotland, for the ten years 1855-64 . . . . .	1 in 111.	1 in 171.	1 in 80.
The five most intemperate registration districts of England, for 1867 (Nos. 1, 2, 3, 10, 11) . . . . .	1 in 112.	1 in 92.	1 in 86.
The five most temperate registration districts of England for 1867 (Nos. 3, 4, 5, 6, 7) . . . . .	1 in 226.	1 in 87.	1 in 79.

No further comment is necessary on this table. It shows conclusively that the Registrar-General's Reports cannot be safely relied on to determine the more delicate etiological problems.

I have now gone over *seriatim* the arguments advanced by Dr. Dickinson, and have, as I believe, succeeded in showing that they are inadequate to disturb the old opinion respecting the effect of alcohol on the kidneys; and that, in fact, the question remains just where it was before

he wrote his article. The only other point which he raises is regarding the proportionate number of granular kidneys in persons who have died of alcoholic cirrhosis of the liver. In forty cases of cirrhosis collected by himself, the kidneys were granular in eight. I may add that Frerichs found granular kidneys the same number of times in thirty-six cases of cirrhosis. In neither series is the proportion strikingly great, but it is certainly not inconsiderable. It must always be remembered that alcohol, like most other causes of disease, works along different lines in different persons, and that its effects vary according to the acuteness and chronicity of its poisonous action. How often does it not happen that we witness the production of cirrhosis from intemperance, without any of the nervous symptoms which usually characterise alcoholism; and, again, how often do we see the latter without the former?

Dr. Dickinson seems to have some difficulty in the *a priori* considerations regarding the way in which alcohol can reach the kidneys to do them injury. The kidneys are certainly less directly in the track of the absorbed alcohol than the liver and the lungs; but they are quite as much so as the brain and nervous system, which are the parts most surely and earliest affected by alcohol—always excepting the stomach.

The mode in which spirit-drinking affects the kidneys is probably twofold. In the first place, it is now well known that alcohol, taken in excess, is largely eliminated in an unchanged state by the kidneys. In the habitual tippler, a frequently reiterated stimulation of the kidneys must arise from this source. Such a stimulation, going on for years and years, can scarcely fail at length in inducing a strong proclivity to organic disease. Secondly, the blood of the intemperate becomes in process of time more or less vitiated, and inadequate to minister to the healthy nutrition of the tissues, and, among others, of the renal tissues.

I do not wish to represent the action of alcohol on the kidneys in too strong relief: the nervous system and the liver are undoubtedly more constantly and earlier affected. But next to these come, probably, the kidneys; and, among the later perils of the less violently intemperate—the steady but not drunken soakers, if I may use the phrase—a high place must, I believe, be given to certain types of Bright's disease.

## NOTES AND OBSERVATIONS ON DISEASES OF THE HEART AND LUNGS.

By THOMAS SHAPTER, M.D., F.R.C.P.,  
Senior Physician to the Devon and Exeter Hospital, etc.

IN the course of professional life, cases of abnormal conditions of the functions of the heart frequently present themselves. These may be classified as (1) errors of impulse; (2) errors of rhythm; (3) the occurrence of pain; and (4) a departure from the heart's usual or normal sounds. These abnormal conditions may exist separately or collectively, and may be due either to organic disease or to functional disorder; now indicative of fatal tendencies, now of only a passing disturbance in the animal economy. To arrive at a correct diagnosis and a safe method of treatment in these cases, it is absolutely necessary to fully, nicely, and accurately appreciate these several and special indications.

It is of the first importance to ascertain if these abnormal symptoms be due to, or in any way associated with, organic lesion. Seeing the book-certainty with which organic disease and its distinctive features are described, it might be assumed that this is a matter of no great difficulty. One of the most experienced observers of diseases of the heart, indeed, says: "The facility of making a correct diagnosis between functional and organic diseases of the heart is not so great as modern writers lead us to believe; and we more often arrive at a just conclusion by instinctive skill, the result of experience and judgment, than by communicable rules of diagnosis." (*Stokes On Diseases of the Heart*, p. 495.)

In the above, as it appears to me, Dr. Stokes begs the whole question of the difficulty of diagnosis in these cases; the accurate judgment of a man of vast experience being made to supersede the deficiency, to the inexperienced, of definite or even suggestive rules. There really is, however, great difficulty, not only in describing the means towards a correct diagnosis between functional and organic diseases of the heart, but the diagnosis itself, even to the most practised and able observers, is too often a conclusion not easily to be arrived at; and this Dr. Stokes himself, in a preceding page, fully acknowledges.

Supposing, however, we can positively and satisfactorily eliminate all

suspicion of organic lesion, it then becomes necessary to ascertain the immediate cause of the functional disturbances exhibited, paying especial attention to such concomitant disorders of the general health as may present themselves. These may not only be the exciting cause of the disordered action, but may have important influences on the future condition of the heart. There remain, in fact, for anxious investigation, the origin and the probable consequences of these functional disorders, with the indications of cure.

In order to arrive at something like rules for our guidance towards the true appreciation and management of these functional disorders, it may probably be useful to consider the several prominent symptoms of diseased action in relation both to organic disease as well as to these latter.

Amongst the prominent and very frequently occurring indications of disorder of the heart, disturbances in the force of its normal impulse must be enumerated. Its force may be diminished or increased. Either of these conditions may be associated with organic disease or with functional disorder only.

The circumstances attendant on, and giving importance to, the condition of a diminished impulse, may conveniently be first considered. A diminished impulse, varying from that which is slightly below the ordinary standard to that which is virtually uncommunicable to the observer, whether by eye or hand, is at times met with; and the due importance of this it will be necessary to appreciate, together with those other symptoms with which it is found to be associated. While we feel that, in many cases, a diminished impulse is consistent with the enjoyment of good health and long life; still it is a condition so often associated with debility in the structure of the heart itself, or with some other important disorder or lesion of the general system, that the study of this symptom and its several associations and probable consequences, is worthy of the physician.

The circumstances whereby a patient's attention is ordinarily arrested when there is the presence of a diminished impulse, are the occurrence of (1) breathlessness on slight exertion, with a (2) feeling of debility, amounting at times to a realised inability to do that which otherwise would be within the usual compass of his power; and this may be associated with (3) the occurrence of occasional faintness, even to actual fainting. On more minute inquiry, we may find, on examination, that there is a diminished (systolic) impulse; and we naturally first seek to find if the heart itself present any objective physical causes for such weakened condition. Is it diminished in size? Is it enlarged? Are its sounds less distinct or more pronounced? The personal condition of the patient is here to be considered, as, in a chest well clothed with fat, but little impulse may be immediately perceptible, though the heart be normal; while in very thin persons, though the impulse is really diminished, the thinness of the walls so far permits it to be felt as may at first induce the idea that its contractile action is not enfeebled.

Due regard being given to these personal conditions, we may, having ascertained that there is a diminished systolic impulse, find it to be associated with (1) a normal condition of the heart as regards size; or (2) a diminished or (3) an enlarged condition; or it may be associated, in addition to either of the above conditions, with diminished or increased valvular sounds, or irregularities in rhythm, or with other indications of cardiac affection; or there may be no indications of a structurally altered heart, but disease in contiguous or other organs influencing the just recognition of the impelling power.

Having duly appreciated the existence and the amount of the diminished impulse, and also the objective symptoms presented by the heart itself, it is necessary to weigh how far the former is dependent on the latter. We must also consider such other remote causes as may exist. Before pronouncing a diminished impulse to be due solely to a passing weakness, it is necessary to carefully eliminate each and all of those associated conditions which indicate it to be due to permanent disease. When this is done, and not till then, are we competent to assume the diminished impulse to be functional only, and such as may be so ministered to as to procure ultimate recovery.

It may be assumed that a diminished impulse is immediately due to a deficiency in the contractile agencies of the heart; and that this deficiency may be in the nervous influences solely, or may be due to permanent physical incapacities. Of the latter, we have illustration in several structural diseases of the heart; of the former, in circumstances, whether passing or permanent, of great physical exhaustion, such as on the occasion of shock, of the specific depressing influences of certain medicines (tobacco, aconite, chloroform, hydrocyanic acid, digitalis, etc.), and of adynamic fevers and other diseases, more especially of the spinal cord and brain-tissue.

Before considering the purely nervous causes of diminished impulse, we will briefly pass in review the circumstances attending this disturbance in the functions of the heart in its connection with some of the

more important structural affections with which this condition is frequently associated, so as the better to appreciate the *rationale* of the influences which produce it, not only in these affections, but in those, also, of a purely nervous origin. The most important structural affections with which diminished impulse is associated, are characterised by a condition of the heart whereby the dullness on percussion in the præcordial region is increased. The physical conditions of the heart in connection with this indication may, in general terms, be referable to (1) dilatation; (2) dilatation with hypertrophy; (3) fatty deposits; (4) deposits in the pericardium; (5) deposits in the pleura. After investigating the distinctive features of each of these conditions, it may be useful to make such notes as may present themselves as to the *rationale* of the deficiency in impulse exhibited in each, and the importance of this deficiency in relation to prognosis and treatment.

In the class of cases now to be considered, those which are associated with, or dependent on, valvular disease will be excluded; observation being limited solely to such as have an independent origin. Nevertheless, we may have to consider cases where the acoustic evidence of mitral murmur is present: this being due, not to valvular disease, but to the amount of dilatation generally, without hypertrophy, rendering the valves insufficient, and thus permitting a regurgitant murmur.

When the impulse is feeble, and there is obviously, on examination, an increase in the area occupied by the heart, as indicated by increased dullness, or by the impulse being diffused, we may assume, without going into an elaborate discussion of the various circumstances connected with contiguous disease or displacements by other organs which may modify the diagnosis, that there is either enlargement of the heart itself, or that there exist abnormal deposits in the pericardium or pleura; and, save when the enlargement is due to concentric hypertrophy, to fatty deposit, or to hypertrophy with softening, we may also assume, if the sounds be louder than normal, that the enlargement is due to dilatation and thinning of the walls of the ventricles.

We will now refer more in detail to the heart-symptoms which may characterise each of these conditions.

When, with the dullness on percussion extending abnormally in a lateral direction, the impulse is deficient in force, and at times slightly undulatory in character, yet diffused over an extended area, and this area, like the dullness on percussion, is extended laterally, but is not to be felt either in the back or below the right shoulder-blade; when, while the apex-beat is apparently seated towards the sternum, its shock is found to be, though diminished and indistinct, to the left of the nipple, and below the fifth interspace, and its shock at this point not more marked or appreciable than over the general area of the heart's position, and the rhythm, though sometimes regular, for the most part disturbed, the pulse being at the same time weak and intermitting, and when the valvular sounds, especially the systolic, are somewhat sharp, clear, and heightened in pitch; when this series of phenomena present themselves, we may infer that there is a generally dilated condition of the heart, the muscular structure of which is neither flabby in texture nor softened by fatty degeneration; and we may also infer the absence of hypertrophy.

Sometimes, however, the above named conditions are qualified by a persistent rhythmical irregularity, with the occasional occurrence of the first sound being absorbed in a murmur; we may then infer that dilatation has proceeded so far as to render some of the valves insufficient. The tricuspid, and then the mitral, are the chief seats of this extended dilatation; should, in extreme cases, the aortic valves also become thus inefficient, the rhythmical action of the heart and the irregularities in the pulse become very marked, while indistinguishable murmurs take the place of the valvular sounds. We may perhaps also infer, when the apparent impulse projects unduly towards the sternum, while both sounds are heard sharp and equal, and sufficiently pervading to be appreciated below the right shoulder-blade, and, at the same time, there is no marked percussion-dullness over the sternum, that the left ventricle is unduly dilated; and we may also infer, if, in addition to great rhythmical disturbance, the jugular veins be unduly distended and present the appearance of an undulating pulsation, that dilatation of the right ventricle exists; and if there be no appreciable abnormal dullness on percussion, we may also conclude that the dilatation is confined to the right ventricle; while if the left ventricle be dilated, we may conclude that the right participates in the like condition.

In all the above cases, we infer the presence of dilatation without special structural degeneration of the parietes of the ventricles. This dilatation, for the most part, exists in both ventricles; but, as just observed, sometimes the right side is solely so affected. As a general rule, the diffusion of the impulse is according to the ratio of the area of the dilatation, while the sharpness and intensity of the sounds is proportionately increased by the thinning of the parietes.

[To be continued.]

## THE CIRCULATION IN THE ACARDIAC FŒTUS.

By GEORGE JOHNSON, M.D., F.R.C.P.,  
Physician to King's College Hospital.

It is satisfactory to me to find that the correspondence between my Reviewer and myself, published some months ago, had sufficient interest for Dr. J. W. Ogle to induce him to write an elaborate paper on the subject of the circulation in the acardiac foetus (BRITISH MEDICAL JOURNAL, Oct. 28th). I had looked up all the authorities now quoted by Dr. Ogle before I commenced the discussion; but I did not refer to them during the correspondence, because the question whether an acardiac foetus had survived its birth could be decided without such reference; and, further, it appeared to me that the speculations of Dr. Houston and Dr. Marshall Hall only tend to throw a cloud of doubt and obscurity over a question which Sir Astley Cooper's dissection had rendered clear and intelligible. I will endeavour as briefly as possible to state the facts of the case.

There is no authentic instance on record of an acardiac foetus unassociated with a cardiac twin. Sir Astley Cooper's dissection and drawings show a direct communication between the two umbilical arteries of the perfect foetus and the single umbilical artery of its acardiac companion. It is obvious, then, that the blood must of necessity be forced by the heart of the perfect child along the umbilical artery of the acardiac foetus, as it was forced *per saltum* from the placental end of the divided cord in the case of twins cited by Dr. M. Hall. It is true that this involves, as Dr. Marshall Hall says, an inversion of the order of the circulation in the cord of the acardiac foetus, the blood passing into that foetus by the umbilical artery, and out by the vein; but this is a necessary result of the fact that *the heart which propels the blood through both fetuses is outside the body of the imperfect foetus*.

The movement of the blood and the direction of its current are determined by the heart. *The blood moves from the heart through the arteries; it returns to the heart by the veins.* This is a law without exception. It is manifest that Dr. M. Hall's hypothesis of "lateral action" involves a reversal of this law, and makes the blood move from the heart through the umbilical vein of the acardiac foetus, and return towards the heart by the umbilical artery. This is an incredible hypothesis, inconsistent with anatomical facts and with hydraulic principles. The only part of the circulation in which the ordinary course of the arterial and venous currents is actually reversed is in the umbilical cord of the acardiac foetus; and this reversal, I repeat, is necessitated by the fact that, one heart having to serve for two fetuses, the central organ of the circulation is external to the imperfect foetus.

Dr. Houston's suggestion that, notwithstanding the free communication between the vessels of the two fetuses, the heart of the one has no influence upon the circulation of the other, but that the placenta has some mysterious power of attracting and repelling the blood, is obviously an untenable hypothesis. Such speculations as those of Dr. M. Hall and Dr. Houston, in opposition to the facts so clearly demonstrated by Sir A. Cooper, remind one of the curious hypothesis of Riolanus, of whom Harvey says, that "he would have the blood to make its way into the left ventricle through the septum of the heart by certain invisible and unknown passages, rather than through those ample and abundantly pervious channels, the pulmonary vessels, furnished with valves, opposing all reflux or regurgitation." (Harvey's Works, Sydenham Society's translation, p. 99.)

Finally, I would suggest that our present knowledge of the functions of the vaso-motor nerves and the muscular arterioles necessitates a thorough revision and modification of the theory of a capillary force and a *vis à fronte*. The case of an acardiac foetus obviously affords no support to that theory. On the contrary, the invariable vascular connexion between such a foetus and a fully developed twin is one amongst a multitude of facts tending to show that, in the circulation of the higher animals, while other influences regulate the supply and distribution of blood, the heart is the main and essential motor power.

## OBSERVATIONS ON THE RADICAL CURE OF RETROFLEXION OF THE UTERUS.

By PERCY BOULTON, M.D., etc.,  
Physician to the Samaritan Hospital for Diseases of Women

DURING the last four or five years it has fallen to my lot to treat a large number of cases of retroflexion of the uterus; and, after many trials of various stems and pessaries, I have arrived at a plan which seems in every way satisfactory. In the JOURNAL of September 23rd I

see a report of Dr. Beatty's paper, which I regret I did not hear at Plymouth; and I wish to record my experience without further delay.

I would commence by endorsing all the advice given by Dr. Beatty as to the preliminary treatment in order to reduce inflammation, congestion, ulceration, etc., before introducing any stem. When the uterus is in a proper condition for receiving the stem, the question is, What kind is the most suitable? Dr. Beatty uses one of Sir James Simpson's, which requires "a flat boxwood pessary in the vagina" to keep it *in situ*. I object to this pessary for the following reasons.

1. The wearing of a stem invariably causes an increased flow of catamenial and other discharges; and such a pessary must retain these in the vagina.

2. It must effectually prevent the passage of the weak astringent wash which Dr. Beatty recommends to be used daily.

3. No examination can be made without removing the pessary; and, "as the bulb of the stem is to rest and move on the smooth surface of the boxwood pessary, and thus allow the uterus to change its position as the woman is horizontal or perpendicular," I think it more than likely that the uterus would become retroverted, and the stem slip out.

4. In most cases a pessary is unnecessary.

My plan is to introduce a self-retaining stem, thus doing away with the necessity of anything in the vagina. I have used various kinds, made of vulcanite or German silver. Those of Drs. Sims, Routh, Bantock, and Greenhalgh, have been preferred; and of these the latter is by far the best. The advantages are, that it is self-retaining, cleanly, being made of German silver, and allowing free escape of discharges; it is easily introduced; and the spring is stronger than the vulcanite ones, and therefore less likely to slip or get out of order.

The first fault I have always recognised. The stem, as ordinarily used after the operation of hysterotomy, is too large to be used in most cases of retroflexion; and I have, therefore, been in the habit of introducing stems identical in shape, but only two inches and a half in length, including the rounded head; and passing the whole within the os uteri. At times the edges of the head have caused pain to the wearer for a short time; but in most cases it has appeared to fit quite naturally within the widened cervix; and the absence of anything in the vagina has always seemed a great advantage. I have used this stem more than any other, and never had any difficulty with it till August last, when the following case came under my care.

Miss E. D. was suffering from melancholia, which was distinctly of a hysterical character. On examination, I found the uterus retroflexed, the fundus forming a tumour between the rectum and cervix. On August 3rd, I passed the sound two inches and a half, straightening the uterus; and then I inserted one of Dr. Greenhalgh's spring stems two inches and a half in length. The patient was anxious to go home to the country; and, as her mental condition rendered it advisable that she should be under constant surveillance, I consented to her doing so, cautioning her to keep very quiet. On September 14th, she came to London to have the stem removed. She had been wonderfully well, and had felt no inconvenience. When I examined the uterus, it appeared perfectly straight; but the stem had gone. I concluded that it had slipped out when at stool, and had not been noticed, as several of the vulcanite ones have done with other cases of mine. I, however, passed a sound gently, and discovered that the stem was in the uterus, but had worked up, the head being nearly an inch from the os externum. I had not much difficulty in extracting it with a copper sound bent into a short hook at the end, which I passed at one side of the stem, and then turned and drew it away.

This case is instructive. The pointed extremities of the open stem must have passed up the cornua leading to the Fallopian tubes; and such a contingency is worth remembering in the future; for, although in this instance the stem was extracted, it might not always be easy to do so.

Not wishing to give up the stem that has hitherto served me so well, I have had a sheath made for the head, with neck and shoulders attached; and this does away with the only faults I have yet discovered. The smooth oval sheath over the head, reduced in size, protects the cervix from the sharp edges which used to cause pain to the wearer; while the shoulders prevent it from working higher up into the uterus, and render it easy to extract. This adaptation of mine makes the stem somewhat resemble Dr. Bantock's vulcanite one; but it is infinitely preferable, and leaves, I think, nothing to be desired.

In most cases of retroflexion, a self-retaining stem is all that is necessary. I have had cases, however, where, owing to increased size and weight of the uterus, from congestion or other causes, or from difficulty of defecation, there has been partial prolapse. In these I always use a Hodge's pessary after replacing the womb and introducing the stem. This takes the strain off the uterine ligaments, and answers every pur-

pose; while the vagina is free from injections, escape of discharges, examination, or what not.

I have had cases where, after the stem was introduced, the uterus became retroverted instead of retroflexed. In these I introduce a Hodge's pessary with bars, which prevent the cervix from tilting forwards; and in that way the uterus is kept in a proper position. The accompanying plate shows the stem as now used.

The addition can be made to any of Dr. Greenhalgh's shorter stems, and in no way interferes with the mode of action or introduction. For cheapness, it can be made of vulcanite, though what I use are metal. This stem can be used after hysterotomy, and has advantages over Dr. Greenhalgh's original one.

#### DILATATION OF THE CERVIX UTERI BY GRADUATED BOUGIES IN CASES OF ANTEFLEXION AND MECHANICAL DYSMENORRŒA.

By ARTHUR W. EDIS, M.D.,  
Assistant-Physician to the Hospital for Women.

How often does it happen in the out-patient department of hospitals, as well as among one's private patients, that the physician is called upon to relieve dysmenorrhœa, sterility, dysuria, and all the numerous symptoms resulting from anteflexion, and yet does not consider it prudent to resort to the intrauterine stem, unless the patient can be admitted or can rest at home, and all the necessary precautions can be taken to preclude any injurious results arising from its introduction. I am well aware that many regard the insertion of a glass, metal, or vulcanite stem as a matter of slight moment, and are in the habit of doing it frequently even among out-patients; but, although it may be done with impunity and even with benefit in many instances, still the proportion of those who have serious symptoms following its employment is sufficient to deter the prudent practitioner from resorting to this expedient until, after the application of leeches to the uterus and frequent passings of the uterine sound, he has accustomed the organ to tolerate the presence of a stem. It is in those patients in whom giving up their employment is simply giving up their means of subsistence, and where, therefore, it is out of the question, that the method which I adopt, and which was practised successfully by Dr. J. Mackintosh forty years since, seems deserving of more extended trial than it at present meets with, and well worthy the attention of practitioners, who are frequently called upon to alleviate the periodic sufferings of those whose life is rendered miserable by what should be a perfectly natural function. The instruments which I employ are similar in form to the ordinary uterine sound, varying in size from that of a No. 8 to No. 12 catheter.

In cases of severe anteflexion, or where this is but slight, and where the internal os or the cervical canal is constricted, a slight amount of inconvenience is generally occasioned by the first introduction. This, however, soon passes off, and gives rise to no further symptoms. My

usual plan is to commence with No. 8, and pass it once a week, gradually increasing the size according to circumstances, and allowing the instrument to remain in for about ten minutes, taking the opportunity to employ it within a few days of the expected appearance of the catamenia. I have found this method of treatment capable of far more universal application than the insertion of a stem; and beyond some temporary inconveniences, such as are met with frequently in passing a catheter in the other sex, I have had no reason to regret in a single case the employment of gradual dilatation. Should any discomfort ensue from the treatment, it is readily alleviated by the use of a pessary containing morphia and atropine. In cases of anteflexion, I always direct the patient to hold her urine as long as possible, thus gaining assistance by the hydrostatic pressure exerted upon the fundus uteri. A mixture of iron and strychnia is also of service; but it will not relieve the symptoms unless other measures be resorted to as well. A few illustrative cases will best explain my remarks.

CASE I.—Mary G., aged 35, had been married sixteen years, and was sterile. The catamenia appeared at the age of thirteen, and had been regular, but always accompanied by pain, commencing about forty-eight hours before the flow, and continuing during the three or four days that it generally lasted. She complained of "bearing down," "forcing of the water," and other usual pelvic symptoms. On examination, the uterus was found to be anteflexed. The uterine sound passed with pain and difficulty upwards and forwards, causing "spasm" at the internal os. A No. 8 thick sound was then passed with some difficulty and pain, causing a "feeling of soreness" for the remainder of the day. It was again employed a few days before the next period, which, as is not unfrequent, was anticipated by two days. Within five weeks from the first interference, menstruation again returned, and, according to the patient's own description, she got through it better than she had done for years, the flow being more free and of a better colour, and not accompanied by any aching or pelvic distress. She has since passed through another period without experiencing any inconvenience whatever; and I have abstained from further interference, in the hope that not merely the dysmenorrhœa, but also the sterility, may be relieved.

CASE II.—Augusta S., aged 38, married seven years, was sterile. The catamenia appeared at fifteen; they were regular, accompanied by pelvic pains and distress during the first two days of the flow. On examination, the uterus was found to be anteflexed, the uterine sound passing upwards and forwards. The thick sound entered with some difficulty. This was repeated three times, at intervals of a week. At the next period, although "she felt as if they ought to come on," nothing appeared. No further interference was resorted to, and she is now daily expecting her confinement. This patient had previously been under the care of another practitioner for "stricture of the womb," and was told that it was impossible she could ever become pregnant.

CASE III.—Emma W., married six years, had one child five years since. The catamenia appeared at the age of seventeen; they were profuse, painful, though regular. She complained of pain in the loins and lower abdomen for about three days before the appearance of the catamenia and during the flow; also of dysuria, etc. The patient was also subject to slight attacks of epilepsy, coming on from excitement or worry. She was admitted as an in-patient in the spring of 1870, and remained six weeks. A glass stem was inserted, but brought on an attack of epilepsy, and the stem was forced out. Every attempt to replace it gave rise to a return of the epilepsy. Further interference was, therefore, desisted from, and the patient left unrelieved. In the spring of the present year she again presented herself in the out-patient department, suffering from the same symptoms. I then commenced carefully the dilatation of the cervix by means of the metal bougies. The first few attempts invariably brought on an attack of epilepsy; but in a short time the uterus became tolerant of interference, and she is now better than she has been for years, and suffers no inconvenience at her periods. The uterus was originally anteflexed; but, owing to the stimulus excited by the passing of the bougies, the atrophied uterine fibres at the angle of flexion have become more developed, and the amount of flexion is considerably less.

POISONING BY PETROLEUM.—In a case observed by M. Lugol, a woman, aged 40, swallowed a full glass of petroleum, with the intention of committing suicide. The pulse was small and thready; no nausea or vomiting; some epigastric discomfort. Magnesia was prescribed in abundance. In the evening there was a stool, on the surface of which swam petroleum, which was easily set on fire. Although the first symptoms were slight, gastro-enteritis presently set in, and death occurred on the twentieth day. (*Repertoire de Pharmacie*, Sept. 1871.)

## ABSTRACT OF CLINICAL LECTURES ON OPHTHALMOLOGY,

*Delivered at St. Thomas's Hospital, London.*

By R. LIEBREICH, M.D.,

Ophthalmic Surgeon and Lecturer to the Hospital.

### EXAMINATION OF THE EYE WITH THE OPHTHALMOSCOPE.

HAVING obtained a general aspect of the fundus, you may direct your attention to the optic disc. In order to observe this important part, it is necessary to make the patient turn his eye twenty degrees inwards towards the nose, and to make him fix a point on a level with your own eye. You will then immediately recognise the optic disc by the vessels of the retina which emerge from its surface. The aspect of the optic disc in the normal eye offers no fewer variations than that of the choroid.

In order to analyse well these variations, it is necessary to understand the signification of certain lines, drawings, and shadows appearing in the optic disc under the illumination given by the ophthalmoscope. There are, first, three different lines in the periphery of the optic disc, to which I gave the names of choroid limit, sclerotic limit, and nervous limit. The choroid limit is the external contour of the papilla. It indicates the edge of the choroid foramen, through which the optic nerve passes. This limit is ordinarily very sharp, and forms, by a stronger pigmentation, sometimes a fine dark circle, sometimes a more or less black crescent, or even a large black circle. The sclerotic limit is not so easy to distinguish. It is more visible in some pathological cases than in the normal eye. It forms a fine, clear, white circle, or ordinarily only half a circle, near the choroid limit, and it is produced by the light reflected from the edge of the sclerotic, where it extends backwards to form the sheath of the optic nerve.

By the side of this white line the darker periphery of the nervous substance is marked by a very fine grey line—the nerve limit proper. Starting from this line to the centre, we find a very delicate shading forming a lighter centre. In this lighter central part we recognise in a certain number of physiological cases a very characteristic drawing, forming a network, the clear lines of which represent the connective tissue of the "lamina cribrosa", while the grey meshes represent the transverse aspect of the nervous fasciculi which pass through the network of the lamina cribrosa. The clearness and extent in which we see this central drawing depend upon the form of the papilla, and especially upon the form and size, and depth of its physiological excavation.

It is very important to study the variations of colour, so as not to make the mistake of taking for pathological changes some exceptionally decided individual, but only physiological appearances. The normal optic disc has sometimes an equal reddish-grey colour; sometimes it is grey in the periphery, and has a very clear luminous centre. In some cases it appears nearly as red as the fundus; and it is in such cases chiefly that we often find established the diagnosis of congestion of the optic nerve;—while I have proved that this red colour is not produced by a stronger vascularisation of the optic nerve itself, but only by an optic effect depending upon the choroid. If the border of this membrane encircle the optic disc more closely, the light, after having traversed the choroid and become red, gives, by dispersion, a red aspect to the papilla.

The manner in which the vessels of the retina are extended upon the optic disc increases, by its variations, the number of different aspects of the papilla in its normal state.

Beyond the papilla the configuration of the vessels of the retina is more uniform, and takes, at least so far as regards the principal branches, nearly always the same direction. This is the reason why it is possible to make the vessels serve as an indication in determining the places in which we have observed some changes. For this purpose I have given, in the first edition of my "Atlas", Plate I, a network of vertical and horizontal lines, each corresponding to a number or a letter serving as an indication of one point in the fundus.

The retina itself exerts only a small influence on the aspect of the normal fundus. Being nearly transparent, it reflects only a very small quantity of light, giving that peculiar hazy appearance which we see the more distinctly as the choroid is darker, because, in such cases, the weak light from the retina is not so completely overpowered by the light returning from the choroid. In children, the retina reflects the light with more intensity, and forms a real lustre, most strongly pronounced near the papilla and the great vessels, forming illuminated circles around the macula lutea.

The macula lutea or yellow spot, the centre of the retina, merits, from its great physiological importance, our particular attention, and it

is generally insufficiently investigated. The characteristic signs of this important point are the following. In the irregular round spot, the size of which is nearly equal to that of the optic disc, the choroid shows a darker pigmentation, both in the epithelium and in the tissue, so that, in dark eyes, this part appears almost black. In the centre of this spot appears a very small reflection, forming either a luminous point or a little ring. This is the reflection of the central foramen. Surrounding this latter we observe a clear yellow film before the choroid, the more intense as it is nearer to the foramen, occupying a different part of the macula lutea in different eyes. This yellow colour is situated in the retina, and is, as I proved many years ago, not merely a cadaveric phenomenon, but exists also in the living eye, although to a smaller extent and with less intensity.

The reflection of the retina, of which we have spoken before as dependent upon the anterior layer (the nerve-fibres), is completely absent in the whole macula lutea, which does not contain a real layer of nerve-fibres.

## THERAPEUTIC MEMORANDA.

### ABDOMINAL PUNCTURE IN TYMPANITES.

IN the number of this JOURNAL for October 21st, is a short but excellent paper by Mr. J. Hancocke Wathen upon Puncture of the Colon for Tympanites, with the opinions of which I cordially agree. The cases which he publishes are all eminently satisfactory, showing the amount of relief given by tapping the bowel for tympany in abdominal disease. But he says, "so far as I can ascertain, abdominal puncture for the relief of tympanites has been performed in five other cases", which he then gives, some of which have already been published. These, however, are by no means the whole of the published cases. If he will refer to the *Obstetrical Transactions*, vol. for 1869, pp. 47, 48, he will find I have recorded the last of four in which I tapped the intestines in May 1867. This paper was read in March 1868. The first case was three or four years before; but I believe that isolated cases have been performed before. I am under correction, but I believe that I was the first to call attention to the operation, although not in so decided a manner as those who have written since. Very recently the question has been under discussion in Paris, where the treatment is commended, twenty cases having been included in the paper.

It has yet to be determined whether there is much risk of extravasation into the peritoneal cavity; but experience at present shows this contingency to be unlikely. If the smallest exploring trocar be employed, the component tissues of the intestine are rather separated than cut, so that the opening is closed as soon as the instrument is withdrawn. One of the dangers of peritonitis arises from extreme tympany, which not unfrequently accompanies its attacks. The pressure of the gas on the sympathetic ganglia and nerves, and the tension of the tissues which they supply, add much to the collapse and vomiting found in the complaint. In such cases, I think, we may also employ tapping, as well as in other forms. But I believe that when the plan has been more extensively tried, it cannot fail to be considered as a legitimate operation in these very distressing cases. The least that may be claimed for it is, that the last moments of the patient can be rendered comparatively free from suffering.

J. BRAXTON HICKS, M.D., F.R.S.  
St. Thomas Street, Oct. 25, 1871.

### ABDOMINAL PUNCTURE IN TYMPANITES.

IN the BRITISH MEDICAL JOURNAL of the 21st October there is an account of some cases of abdominal puncture for the relief of tympanites, and in it reference is made to a case occurring in the practice of Mr. Salmon of Thornbury, where it much mitigated the patient's sufferings during the remaining twelve days of her life.

A similar case occurred to me in August 1869. The patient, a little boy aged three years, was suffering from peritonitis, presumed to be tubercular, and attended by great pain and tympanitic distension of the abdomen. The child's sufferings were very acute, notwithstanding the free use of opiates, and I fully expected that he would sink in a day or two. Hoping to give some relief, I punctured with a small trocar, letting out a large quantity of fetid air, followed by a drop or two of pus. As this gave great and immediate relief, I repeated the operation in a few days, when there was some reaccumulation. To my surprise he entirely recovered, and by the end of November was well, and remained so for about sixteen months, when he was attacked by whooping-cough and bronchitis, of which he died in April 1871. As his illness and death occurred at a distance from here, I had no opportunity of making a *post mortem* examination.

Ealing.

G. D. BROWN.

## ABDOMINAL PUNCTURE IN TYMPANITES.

IN the issue of October 21st I observed an article "On Puncture of the Colon for the Relief of Tympanites", in which the writer makes the following statement in proof of the propriety of such an operation for tympanites in the human subject. He says: "You are all, no doubt, well aware that puncture of the intestine has long been practised on the lower animals. . . . The treatment is simple, and well known to most graziers. . . . I have just been informed by a most intelligent farmer that he has repeatedly performed the operation, always with the best results, never having lost a case."

Now it behoves all scientific men (more especially medical men), in advocating a new system of treatment, or in reviving an old one, where the life of a human being may be at stake, to be accurate in their narration, and have correct sources of information. Mr. Wathen has been simply misinformed; and if he had referred to any veterinary works bearing upon the subject, he would have been put right. The operation that he describes as "puncture of the intestine" in the ox is, in fact, puncturing the first stomach (*rumen*), and, as he states, is a very common operation. The *rumen* is not very liable to suffer from inflammation, so that we can operate upon this organ with impunity. It is customary with veterinary practitioners not only to puncture it, but to incise it to the extent of seven or eight inches, and remove its contents by the hand (occasionally removing about 112 lbs. in weight), and then introduce medicinal agents, at times using a flour-dredger to dredge the internal surface of the stomach with powdered nux vomica, etc. Thus it will be seen that there is no analogy between the cases which he quotes and the operation which he describes as being frequently performed on the lower animals; nor does the success of the one justify the performance of the other in the human subject. I do not think that Mr. Wathen would recommend his brother practitioners to operate upon their patients in this heroic manner.

Puncture of the colon for tympanites has, however, been performed on the horse, though with very little success; and, as far as my experience goes in such cases, I cannot recommend its adoption in the lower animals. There are several reasons for this opinion, but one significant fact may be sufficient at present. The intestines of herbivorous animals contain a large quantity of fluid, which, during the very violent struggles of the animal, is nearly certain to pass into the peritoneal sac, and thus give rise to a severe form of peritonitis, followed, in all probability, by death. This is no theory, as the *post mortem* appearances in such cases are so well marked that there can be no mistake in our conclusions.

With regard to the advisability or success of this operation in the human subject, I have nothing to say; but I should think that, as medical men have not the same difficulties and dangers to encounter in this operation that we have, it should be followed by greater success in their practice than in ours.

JOHN A. MCBRIDE, Lecturer on Veterinary Medicine and Surgery in the Royal Agricultural College, Cirencester.

## TREATMENT OF GANGLION AND DIARRHŒA.

THE publication in the JOURNAL of the Reports of Medical and Surgical Practice in the Hospitals of Great Britain, conveys valuable information as to the views held and treatment adopted by our eminent members of the profession in various maladies, and certainly will be the best means of guiding the practitioner in his daily work, and of advancing the knowledge of pathology and therapeutics.

In the treatment of ganglion, no mention has been made of electrolysis; and, having experienced in private practice during the last four years the beneficial effects of the electrolytic needle, I am induced to add my observations to those already published in the JOURNAL. Miss T. O. consulted me in September 1867. She had during twelve months, after scarlatina, a ganglion an inch in diameter on the left wrist. I introduced two gilt needles, connected with the negative pole of a galvanic battery (four Daniell's cells), into the tumour, and closed the circuit by applying a wet sponge connected with the positive pole to the skin near the tumour, and allowed the continuous current to act for ten minutes. No pain was felt during or after the operation. I repeated it at intervals of seven days, during which time the tumour gradually diminished in size, and entirely disappeared after the fourth application. I saw my patient lately, and there is no trace of the ganglion left. In a second case about the same time, I obtained a permanent cure after two operations. I have since treated several cases of ganglion by means of electrolysis, and have been likewise successful.

With regard to the treatment of diarrhœa, I have tried in some cases opiates and astringents, and in others purgatives. I have seen better effects from the latter plan, and am therefore in favour of the elimina-

tive treatment of diarrhœa, cholérine, and Asiatic cholera, these being, in my opinion, only various degrees of one and the same malady.

A. WAHLTUCH, M.D., Manchester.

## CLINICAL MEMORANDA.

## EMBOLISM OF THE LEFT VERTEBRAL ARTERY: PARALYSIS OF THE GLOSSO-PHARYNGEAL NERVE: DEATH FROM STARVATION.

T. C., aged 68, a labourer, of full habit and florid complexion, met with an accident two months before his death, falling from a load across the back of a horse on his sternum. There was severe concussion of the chest, with considerable dyspnœa, but no ribs were broken. A few days afterwards, he complained of great pain over the left side of the occiput, extending down the neck; this gradually ceased, and he recovered so as to be able to walk about.

On October 14th he had a violent fit of sickness, and in the course of the day found he had entirely lost the power of deglutition. He complained of numbness in the right arm and leg, but had perfect motion. The pupil of the right eye was dilated, but sensible to light. He expressed himself as feeling quite well, only very hungry. He made the most determined attempts to swallow, but the fluid always returned by the nose. An open blister was made at the back of the neck and dressed with strychnia till tetanic twitchings were produced, and beef-tea enemata were given freely. He sank from exhaustion on October 26th. On removing the brain at the necropsy, that organ was found perfectly healthy, with the exception of the left vertebral artery, which was entirely filled up with an embolic clot.—[Query: Had this any connection with the accident?] HENRY TAYLOR, Ixworth.

## REPORTS

OF

## MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

## KING'S COLLEGE HOSPITAL.

## CANCER OF THE STOMACH.

(Under the care of Dr. GEORGE JOHNSON.)

THE following case is of interest from the rapid course of the emaciation and other symptoms, and the absence of much pain or vomiting, until within a month of the patient's death. The œdema of the legs was consequent, no doubt, on the obstruction to the flow of the blood through the inferior vena cava, caused by the nodular mass surrounding the pancreas, and lying in front of the spine.

C. W., aged 52, widow, was admitted into King's College Hospital, under the care of Dr. Johnson, on September 4th, 1871. She had enjoyed good health until twelve months ago, when she suffered for six weeks from symptoms of dyspepsia. She then continued feeling quite well until a month before admission, when she felt "a swelling in her stomach"; at the same time she lost her appetite and became somewhat thinner; still she was not sick, nor was her appetite impaired.

On admission, she was a well-nourished woman, with an anxious expression of countenance. She then had a bad appetite, was occasionally sick, and had pain in the epigastrium. The chest-sounds were healthy; the urine was normal; the liver-dulness was normal. In the epigastric region, just below the liver, a tumour could be felt extending towards the left hypochondrium; it was firm and nodular, and seemed to lie transversely; it gave no marked pain on pressure. The temperature and pulse were normal. On September 16th, she was noted to have lost seven pounds in weight during the previous week. The countenance was more anxious, and there was an expression of pain. The tumour in the epigastrium was much larger, and felt more superficial. There was now much sickness, loss of appetite, and inability to sleep at night. The feet and legs began to be puffy, and there was much prostration. Hypodermic injections of morphia considerably relieved the pain. On October 5th, she evidently had become much weaker and thinner; the pain and loss of appetite had become more marked; she vomited frequently, yet there was no hæmorrhage from the stomach. The abdomen was much distended with flatus; and the tumour could not be felt so distinctly. She continued becoming weaker until October 9th, when she died.

Necropsy by Dr. Kelly, thirty hours after death.—There were one

or two old adhesions in the right pleura; the lungs were pale and bloodless, and readily collapsed on opening the chest. There was no morbid deposit in the thorax. There was a smooth white patch over the right ventricle; otherwise the heart was healthy. The liver weighed eighty-one ounces. It was large and smooth on the surface. Scattered through its substance were a great many cancerous nodules; most of them were near the surface, and seemed to correspond to terminal branches of the portal vein. The most recent were slightly concave in the centre, and of a milk-white colour, while around there was a yellow zone of cancer-cells, and outside this an injected vascular zone. The older deposits were of a yellowish colour, and slightly raised above the surface. No patches were more than half an inch in diameter, while most of them were much less. The kidney and spleen were healthy. Below the stomach, surrounding the pancreas, and lying in front of the spine, was a large mass of cancerous glands. The intestines lay in front, and were not diseased. The mass was firm, nodular, and closely surrounded the aorta and inferior vena cava. The tumour felt during life was the most prominent and superficial portion of this mass. The stomach was found much diseased. Its coats were much thickened by cancerous infiltration into the submucous tissue, while the muscular coat was but little invaded. The serous coat was healthy. The mucous membrane was not ulcerated, but much injected in patches. The cancerous deposit in some places was nearly an inch thick, and ended very abruptly at the pyloric orifice. The stomach was small and empty. There was no other morbid condition met with.

### LONDON HOSPITAL.

#### CASE OF TUMOUR OF THE MIDDLE LOBE OF THE CEREBELLUM.

By J. HUGHLINGS JACKSON, M.D., F.R.C.P., Physician to the Hospital.

I WISH in this communication simply to record a case of clinical interest, and not to make a case the text for remarks on the functions of the cerebellum. This is the fifth case of disease of the cerebellum which I have had under my observation since January. The symptoms in these five cases were so different, that I am less inclined than ever I was to make general remarks on cerebellar disease. As in lesions elsewhere, we have to classify our cases of cerebellar disease with especial regard to the suddenness or slowness of the lesion. Cases of cerebellar hæmorrhage and cases of tumour of the cerebellum seem to differ even in kind. The case which I relate is one of tumour, and of tumour so placed that the diagnosis was comparatively easy.

John R., aged 5, was admitted April 25th, and was afterwards transferred to my care by Dr. Andrew Clark. Copious and very careful notes of the case were taken, chiefly by Mr. Stephen Mackenzie; and of these the following is an abstract.

*History.*—The boy had cut his teeth early. He walked at the age of thirteen months, and, except for two convulsive seizures, both on one day, when (his mother said) he was cutting a top tooth, he had been healthy. Four months before admission, the illness of which he died began. The first things noticed were, that the boy's head became so much larger that his father's cap would fit him, and that he complained of pain at the back of his head. He cried a good deal, and lost flesh. Two months later, he began to be "stupid". Fourteen days before admission, his legs began to fail in walking; and, two or three days before admission, he began to pass urine and feces without notice.

When admitted, he seemed to be in good general health. He took his food well; and, although his mother said he had become thinner, he was well nourished. In what follows, the particulars of his case will be arranged under the following headings: 1. Mental condition and size of head; 2. State of optic nerves and condition of sight; 3. State of limbs; 4. Convulsive seizures.

1. *Mental Condition and Size of Head.*—His mental condition was very peculiar. He very rarely spoke, except when spoken to, or when he wanted something to eat or drink; but he did talk well on these occasions. He had picked up a phrase since his admission into the hospital. When any one asked him "What does the dustman say?" he would give a remarkably exact imitation of the dustman's cry, "Dust a-hoy." At a later date, he sang, the nurse told us, in good tune, two lines of a hymn; and, when Mr. Mackenzie asked him to sing it again, he got out the words "Angels of Jesus", pitching his voice properly. His memory was very delicate; he could not remember the name of his next bedfellow; did not care to see his father or mother; and it was doubtful if he recognised his mother. He did not play. He was, however, very good-natured, and, as the nurse said, "biddable". Indeed, for his age, he was abnormally good-tempered—to a degree of apathy. His general mental condition is best described by

the word Mr. Mackenzie uses in his report—"hebetude". There was a general fading out of mental power.

He had a large head, but there was nothing characteristic about its enlargement. The orbital plates were not depressed; no gaping of the sutures could be detected; and there was no great prominence above the ears. It did not become much larger before death. There was no evidence of rickets in his history, nor were there any relics of it in the shape of his chest.

*Optic Nerves and Sight.*—At first, his sight was not obviously affected; but it was impracticable to test it. Neither the boy's mother nor his nurse supposed that there was anything the matter with it, although Mr. Mackenzie found that there was double optic neuritis. On May 11th, when I for the first time used the ophthalmoscope, there was no obvious imperfection of sight; both optic discs were much swollen and raised; the arteries were concealed in the swelling; the veins were large, and partly obscured, "knuckling" over the edge of the disc. The surface of the disc was of a nacreous appearance. There were no effusions of blood, nor did any appear afterwards. He subsequently became blind. The discs gradually cleared up to a remarkable extent, and on the day before his death they were of little more than normal size, but were indistinctly edged and a little swollen. Since headache and vomiting often occur with this pathological condition of the discs, it is not out of place to mention here that, during the boy's stay in the hospital, he did not seem to have pain in the head. He vomited frequently, but had no dyspepsia, taking his food well almost to the last.

3. *Limbs.*—When I saw him, he could not walk by himself, but, when helped a little, could reel along. His gait was a reel, not a stagger like that of ataxy; nor was it the gait of paraplegia. Whenever left to himself during the trial of his walking, he fell to the side to which he was inclining. Subsequently to the fits (to be presently described), both legs became permanently stiffened in a line with his body, the feet being strongly extended, and to a trifling extent turned in. As will be seen, this permanent set of the boy's legs was like their condition in the fits which preceded them.

4. *Convulsive Seizures.*—The first was on May 5th. The nurse called these "shocks", and said that both legs became rigid. He had many of this kind, but at very irregular intervals. Several of these seizures were carefully watched by Mr. Stephen Mackenzie. The following is Mr. Mackenzie's concluding report of the case, and contains an account of several seizures which he saw.

July 11th. There had been no material change in his condition for some time, except a progressive loss of flesh. He was now much emaciated. His mental condition continued of the same character. He lay still, and never spoke unless he was spoken to; and his replies were always monosyllabic. He now could utter another street cry—"Any watercresses?"—in good intonation; and, when saying it, smiled, which he never did when saying anything else. When he was asked who any one near him was, he invariably replied "Granmother"; and, in answer to the question "How are you to-day?" he invariably replied "Nothink". The great test of his bodily strength each day had been the degree of vehemence with which he could utter "Dust a-hoy." To-day his voice was piteously feeble. He was much weaker, but still took his food well. He had had convulsive seizures every few days, several of which Mr. Mackenzie saw. Sometimes, but not always, the seizure was preceded by a loud cry. There was no marked twitching of the face, nor any special deviation of the eyeballs. His hands were clenched; his forearms were flexed on the upper arms, which were generally kept to the sides. The head was drawn back, and the back was curved. His legs were always extended to the fullest possible degree, the feet being arched backwards. Sometimes he passed feces and urine in an attack. The seizures generally lasted about three or four minutes; and, when passing off, they returned if he were moved about. He was not unconscious. There was no clonic spasm. In one attack, the two eyes were turned to the left, and the head to the right—not backwards, as usual.

July 21st. For the last three days the patient had been much worse. He had been lying during this time in almost exactly the same position—partly on his chest, and partly on his left side, lying askew. His back was arched backwards; the head was retracted apparently to the greatest possible degree; and the legs were fully extended. But now and then there was a perceptible increase in the rigidity. He could not swallow either solids or fluids, but answered simple questions. His "Dust a-hoy" was painfully feeble. He died next day.

*Necropsy.*—The body was much emaciated, but no disease was found in any part of the body except in the head. The head was large; the cranial bones were thinned; and the sutures were loose. The convolutions were flattened, and the cerebral ventricles were distended by fluid; the horns of the lateral ventricles were much dilated. There was a growth like that in the cerebellum, involving, and, as it seemed,

replacing, the right corpus albicans. The tentorium was much bulged upwards; and under it was found a tumour of the middle lobe of the cerebellum, of about the size of a billiard-ball. The corpora quadrigemina were much flattened, and the veins of Galen were greatly dilated. The tumour, on section, was of a grey green colour. It was rounded, easily separable. Its surface was defined and vascular. Dr. Moxon was so kind as to examine the tumour for me. He concluded that it was tubercle, partly from the facts stated, partly from the microscopical structure, and partly from the age of the patient and the absence of evidence of syphilis in the clinical history. He reported on the microscopical structure as follows. "Though it presents a great variety of elements in small quantity, yet by far the main part consists of the small rounded corpuscles that usually characterise tubercle; better formed and varying corpuscles being in the outermost part, and the 'tubercle-corpuscles' deeper."

REMARKS.—The diagnosis in this case was not difficult. There were three chief symptoms: 1, enlargement of the head; 2, blindness; and 3, reeling gait. Each of these symptoms by itself would be of uncertain value in diagnosis. The enlargement of the head might be owing to an adventitious product in the cerebrum—a large hydatid cyst, for instance. In such a case there might be an irregular gait, very like the reeling which was observed in the boy's case; but there would be, if not decided hemiplegia, much more weakness of one side of the body than of the other. The blindness from optic neuritis was of no value as to the position of the lesion, as tumour in very many parts of the encephalon gives rise to double optic neuritis. Perhaps, of the three symptoms, the reeling gait was of most value, but by itself would only point to tumour under the tentorium. Putting the symptoms together, it was supposed that there was a tumour of the middle lobe of the cerebellum, which pressed on the veins of Galen and straight sinus, and thus caused, so to speak, "ascites of the brain" (hydrocephalus). I made this diagnosis with confidence, because I had some years ago seen a case almost quite like that of my patient under the care of Dr. Gull. Dr. Gull without any hesitation diagnosed tumour of the middle lobe of the cerebellum, and this was found *post mortem*. Again I made a diagnosis in a similar case a year ago—correctly as to the position of the disease, altogether incorrectly as to its nature. Lastly, a few months ago Mr. Waren Tay showed me a case in which, from the presence of like symptoms, he correctly diagnosed tumour of the middle lobe of the cerebellum.

The symptom which is the most interesting in the case is the convulsive seizure. I regret exceedingly that I have mislaid a sketch of the boy's position in one of the severest of these seizures. The back was much more arched than is represented in the drawing handed round. It is important to contrast this seizure with those which are more often seen from tumour of the cerebrum. In these cerebellar convulsions, the spasm was chiefly tonic. In cerebral convulsion, it is chiefly clonic. In this case, the convulsion affected most the bilateral muscles of the trunk and the legs; whilst in cerebral convulsions the unilateral muscles are most affected, and the arms are more affected than the legs. In the kind of spasm, and in its regional distribution, it resembled rather tetanus than epileptiform convulsions; and, although the paroxysm differed from what is most commonly seen in the paroxysm of tetanus, it was enough like it to serve as a fragment of evidence in support of the view that the changes in tetanus are in the cerebellum. The cerebellum seems to represent the muscles of the body in an order the reverse of that in which they are represented in the cerebrum. The current view is, that the cerebellum co-ordinates more especially those movements which serve in locomotion and other quasi-automatic processes; whereas the cerebrum co-ordinates more especially the movements which serve in voluntary operations.

#### UNIVERSITY HOSPITAL, BERLIN.

##### EPITHELIOMA OF THE LARYNX: LARYNGO-TRACHEOTOMY: APPLICATION OF THE ACTUAL CAUTERY: RECOVERY.

Philip Boschwitz, aged 28, was admitted an in-patient in the Royal Klinikum, Berlin, under Dr. von Langenbeck. He had had the disease between three and four years. It came on very gradually. During the past few weeks, it caused such difficulty in breathing, that, especially at night, he would sometimes have fits of asphyxia of several minutes' duration. He could swallow well. There were no other abnormal signs in the lungs than those of slight general bronchitis. The man, who was a tradesman, was rather pale and cachectic.

A laryngoscopic examination showed that the entrance of the larynx was free; the epiglottis was normal, as were also the vocal chords, both in movement and outward form. Below the vocal chords could be seen a swelling of raw surface, uneven, which proceeded from the anterior

commissure to the left and below the left vocal chord, involving, therefore, the left half of the larynx.

It was first proposed to remove the tumour through the larynx; but this mode of operation was ultimately rejected, because the swelling appeared to have a broad base, and further extended to some distance below the chords, of which, however, there was no abnormal sensibility. The operation of tracheotomy was, therefore, performed on May 25th. An incision was first made through the crico-thyroid membrane, and was extended upwards through the thyroid cartilage nearly as high as the attachment of the vocal chords, and downwards through the cricoid cartilage as low as the third ring of the trachea. The vocal chords were not in any way injured; and, on looking up through the wound, they and their movements could be seen quite distinctly. Immediately on opening the trachea, the tumour showed itself. It was seized with forceps, pulled out, and cut off; and the place where it had sat was well cauterised with ferrum candens. The bleeding, which was slight, was arrested easily with a small sponge; a cannula was introduced, and the upper end of the skin-wound was closed with one or two sutures.

Bronchitis came on for a day or two, but again gradually subsided, and all went well. The cannula was withdrawn on the fifth day, and the edges of the wound were brought together by strips of adhesive plaster.

The patient quickly recovered: the wound healed, with the exception of a small fistulous opening, through which air passes when he coughs or otherwise exerts himself. His previous difficulty in breathing has entirely vanished, and he now awaits his discharge cured.

It had been a question at one time to perform a prophylactic tracheotomy, with the view of introducing Dr. Trendelenburg's cannula, which, when introduced, most thoroughly prevents any blood or other foreign matters from reaching the lungs.

## THERAPEUTIC RECORD.

POWDERED CAMPHOR FOR HOSPITAL GANGRENE.—*Apropos* of M. Netter's recommendation of this application, M. Briquet recalls the fact that in 1814 and 1815 hundreds of patients were so treated, and since then Dr. Rousseau of Eprenay has published similar cases.

HYDROTHERAPEIA IN INFANTILE PNEUMONIA.—Dr. Buch (*Allgem. Med. Central-Zeitung*), in cases where the temperature rises to 39 cent. (102.2 Fahr.) or above it, carefully wraps the child in a folded sheet well wrung out in cold water, leaving only the mouth and nose exposed. In less than three minutes, when the sheet has become warm, the child, clothed only in a night-dress, and without being dried, is put to bed and lightly covered, so that its temperature shall not rise again to 39. If the first wrapping do not bring it down to 38 cent. (100.4 Fahr.), he applies another. The immediate result of this treatment is said to be the return of sleep, and increased ease of respiration and expectoration. He gives also nourishing diet, with wine and quinine.

CIRCUMSCRIBED FALSE SUBCLAVIAN ANEURISM: INJECTION OF ERGOTIN.—Dr. Dutoit of Bern relates, in Langenbeck's *Archiv* (Band xii, No. 3), a case in which he successfully employed the injection of ergotin for the treatment of aneurism. He was led to this course by the perusal of the accounts of two cases of aneurism related by Professor von Langenbeck some time ago, in which ergotin was successfully injected. His patient was a man aged 40, in whom the aneurism had been produced by an injury received in 1866. When he came under notice in October 1869, there was behind the left clavicle a tumour as large as an ostrich's egg, presenting all the characters of an aneurism. Ergotin was injected over the tumour (from a solution of one drachm in three of alcohol and three of glycerine) every second, and later every third day; the quantity being gradually increased from one-third of a grain to three grains. Fifteen injections were made between October 25th and December 1st. Marked diminution of the swelling was noticed after the fourth injection; and from this time it steadily continued. The injections produced pain for about two hours. There was no suppuration, but the skin and subcutaneous tissue were hardened, so as probably to compress the aneurism. In the beginning of December, the swelling having disappeared from the supraclavicular fossa, digital pressure was applied three hours in the afternoon and the same length of time in the afternoon for six days, with the effect of causing the total disappearance of the swelling. For security, at a later period ten injections of three grains each of ergotin were made at long intervals, and a light compress and bandage were worn.

THE Subscriptions to the Association for the year 1871 became due in advance on January 1st. All which are not already paid, should be forwarded to the General Secretary, Mr. T. Watkin Williams, 13, New Hall Street, Birmingham; or to the Secretaries of Branches.

## BRITISH MEDICAL JOURNAL.

SATURDAY, NOVEMBER 4TH, 1871.

### THE MEDICAL PROFESSION AND THE WORKING CLASSES.

DR. ALFRED SHEEN, Surgeon to the Cardiff Infirmary, has communicated to us some interesting observations on the unsatisfactory relations of the medical profession to the working classes. He considers the subject from two points of view. He observes that there are at present at the disposal of the working classes, for obtaining medical assistance in ordinary sickness, the infirmary, the benefit societies or "clubs", the parish medical officer, and, lastly, private medical attendance. These, he considers, all have their evils as affecting this class. The infirmary and the parish are demoralising to a certain extent, because they are eleemosynary, and a large number of the patients relieved by them could afford to pay a small fee if they had the opportunity of doing so. There is also a difficulty surrounding the obtainment of "tickets", more especially in the case of an infirmary, which must be detrimental in cases of acute illness, when much valuable time is thereby lost; and the same remark applies with those who, from feelings of delicacy or other motives, delay seeking advice through these channels until compelled through the nature of their illness. The parish medical relief, where that alone is required, is particularly demoralising, because, as a rule, it is easily obtained, and little valued afterwards. The club-system is the nearest approach to an organised system of medical relief for the working classes, but it is very faulty, even as it affects their welfare. It is notorious that a large number of club-patients think less of their own doctor than of an outsider; and this feeling Dr. Sheen believes to have its origin, unperceived perhaps by the class itself, in the low rate of payment made by clubs to their surgeons. Then, again—and this is a very grave fault—it only, as a rule, recognises relief to men, leaving out altogether their families. It also limits the age, and accepts none but healthy men. It has other faults which affect the profession.

As *private patients*, the lower orders are ever ready to seek advice, but unwilling in some cases, and unable in many more, to pay. As to the inability to pay, when poor people are ill, they must have advice from some quarter, and they will often rush to a medical man with all honest intentions of paying him; and few are the members of our profession who will higgie about the payment when sent for in a case of this kind. Speaking of the medical attendance as it affects the class itself, practically the lowest fee ordinarily charged is too high in a long attendance on a patient of the lower orders; and yet they have no alternative but to apply to the infirmary or to the relieving officer. This ought not to be; it is not what they should be driven to, or what we should be satisfied with. They ought at all events, to have the opportunity given them of obtaining medical help without lowering their own independence. Thus, Dr. Sheen has long been of opinion, is only to be brought about by the systematic and thorough organisation of the Provident Dispensary System. He believes that one of the greatest evils of the present age, and one of the proximate causes of increasing pauperism, is the ready obtainment by poor people for *nothing* (an abuse of charity) of that to which they ought to attach a certain money-value, however small it may be.

From the point of view of professional interests, besides the pay-

ments of benefit societies being so low as to encourage a habit of indifference on the part of the surgeons, a large number of members of clubs, claiming medical attendance as such, are in a position to pay the ordinary fees of medical men. It might be possible in the future, if provident dispensaries became generally established, to induce the benefit societies to separate their money relief from their medical relief, and attach the latter to the provident dispensary of the neighbourhood.

The private patients of the lower orders are those who give medical practitioners the greatest anxiety and trouble. A junior practitioner does a large private practice amongst the members of this class of society—for somebody must do it: he "books" every week with some satisfaction the amount due, and looks forward with confidence to the coming Midsummer or Christmas for an accession of funds to meet the *res angusta domi*. Several of his bills, however, come back to him through the Dead-letter Office; a few others are paid; and as to the rest, alas! for these his only remedy is the County Court or to go without his due. The latter course he frequently accepts as the more dignified. An inward misgiving on the part of the medical attendant of the patient's inability or unwillingness to pay does not have the effect of increasing that intimate confidence which ought to exist between the patient and doctor.

The abuses of the out-patient departments of hospitals have been freely and ably discussed of late. Dr. Sheen does not think, however, that they exist to the same extent in the country as in London and other very large towns.

The general establishment of provident dispensaries has a most important bearing on the Poor-law dispensary system, which, it is hoped, may soon be established throughout the country.

These views, coming from a practitioner of Dr. Sheen's intelligence, and one who has excellent opportunities of gathering professional opinion in his neighbourhood, seem to us of importance. They bear out very largely the observations which we have already made. The subject is one of so great importance to the profession and the public, that we have willingly given great prominence to it, and shall not grudge further space. We invite the attention of our correspondents to this subject, and to the rules for provident dispensaries which we published last week.

### SCHOLARES NON ASCRIPTI.

WE have from time to time drawn the attention of our readers to the changes which have been made by the authorities of the University of Oxford in order to meet the wants of the day and the demand which there is for cheaper University education. To-day, we are desirous to lay before them some of the results which have been attained by the system of "unattached students"—a system the flexibility of which may recommend it to some of our associates who are desirous of sending their sons to the famous seat of learning on the banks of the Isis.

It is now three years since the statute was passed which enables students to be members of the University without belonging to any college or hall. Of these "*scholares non ascripti*," there were by the last report 106 on the books; and we understand that the fresh entry, which has just taken place, is extremely encouraging. Special tutors and censors are appointed to look after the discipline and to direct the studies of the unattached students, and the statements which these delegates make as to the success which has attended the system are most interesting.

The educational advantages which the "*scholares non ascripti*" enjoy are very great. Not only are the public or professional lectures of the University all open to them (including the whole course of instruction at the magnificent new Museum of Physical Science), but many colleges admit them to their tutorial lectures on very easy terms. Thus, so far as the educational advantages of the place are concerned, they stand in an unusually favourable position. The whole of the University degrees

and distinctions are as open to them as to any other students, and they share, in common with the rest of the undergraduates, all the facilities which have during the last few years been afforded to those who desire to devote themselves to some special branch of study. And here we would point out that the University does not now require a knowledge of Latin and Greek from those who do not intend to follow the Arts course. This is an alteration which may have an important bearing upon those aspirants to the medical profession who are anxious to enjoy an University training. Though it is not desirable that any should enter our ranks who have not that slender acquaintance with Latin and Greek which the matriculation examination requires, still it may not unfrequently happen that those who have been preparing themselves for medical study prefer to offer Botany and Chemistry, or French and German, instead of Latin and Greek. Anything which gives elasticity to the curriculum of study at our "old universities"—anything which makes their course of training better suited to meet the wants of actual life, will be welcomed by such a practical profession as ours. The introduction of a class of "unattached students," who may live with their friends, or in lodgings of their own selection, is a great step towards extending the usefulness of Oxford as a place of national education, and the various alterations which have been made in this system since it was first adopted have all been changes in the right direction.

But it may be asked, what is the yearly cost of this system to a careful undergraduate? It was introduced with the object of cheapening University education; has it answered that end? To this question the delegates give a very clear reply. Twenty "unattached students" voluntarily made a return of their expenses, and "the average weekly cost of living (board, lodging, and extras) on the twenty returns was thirty-one shillings. But if the lowest ten be taken, the average falls to twenty-six shillings. Taking this average as the sum per week for which a thrifty student can get respectable board and lodging in Oxford, we arrive at the following figures for a year's expenses. Board and lodging for three terms of eight weeks at twenty-six shillings, £31 : 4; University dues, £4 : 10; examination fees (on an average), £1 : 1; tuition expenses (about), £10 : 10; total, £47 : 5. It will, of course, be observed that these figures do not include travelling, books, clothes, pocket-money, or cost of living in the vacations. Still they prove that a careful student can get through his Oxford career for a sum not exceeding £50 a year."

Moreover, the system seems to be as favourable to quiet industry as it is to economy, for the report adds:—"The students appear to the delegates to have used great diligence in their work, and, by their steady and blameless conduct, to have shown themselves fully worthy of the privileges of greater independence which they enjoy. When it is remembered that there are now above a hundred of these students, it is satisfactory to know that there is not the slightest symptom of any of the moral evils which were dreaded by some persons at the time when the statute for their admission into the University was passed."

On a former occasion, in alluding to this subject, we said that if the system of "unattached students" could be carried out as its promoters desired, it would entirely meet the demand for a cheaper University education which has often risen from the ranks of our profession; and now we can announce that it is not only in full operation, but its success has been even greater than its well-wishers could have anticipated.

#### THE EDUCATION OF THE DEAF AND DUMB BY LIP-READING AND ARTICULATION.

THE notice of the profession has been lately directed to a method of instruction which, if it obtain in this country the same acceptance as it has already done in Germany, Holland, and Belgium, will have the effect of modifying, if not completely changing, the system which is pursued with us at present in the education of deaf mutes. The influence which the general opinion of the profession will have in deciding upon any reform in this respect will be very considerable, and we there-

fore again call the attention of our readers to the subject. The mode of conversing now taught at our asylums for the deaf and dumb is, as every one knows, by the finger-alphabet and by manual signs; but a new system is now in vogue in the countries which we have specified, by which the education of the deaf and dumb is carried out by means of lip-reading and articulation. It appears, from a paper read at the recent Social Science Congress at Leeds, by Mr. W. B. Dalby, of St. George's Hospital, that the education is commenced at the age of seven, and that it extends over a period of seven or eight years. At the end of that time, provided the children are possessed of ordinary mental capacity, they are able to understand, by reading from the lips, what is said to them by ordinary persons, and to make use of articulate speech, which, although not euphonious, can be plainly understood. For the first few years of education considerable patience and skill are demanded on the part of the instructor; but, as partially trained teachers are sufficient for the more advanced pupils, it is not found difficult to obtain instructors. It is impossible to combine successfully the two methods; for, so long as the children employ the finger-alphabet, and their attention is thus withdrawn from the lip-movement, they will not exercise the necessary perseverance to learn articulate speech, and it is owing apparently to attempts having been made in the country to mingle the two systems that the failure in establishing the so-called German—but originally English—method is attributable.

Mr. Dalby introduced to the section at Leeds, Mr. Polano, a Dutch gentleman, who, born totally deaf and dumb, had been taught to speak both Dutch and German; he conversed in the latter language with several gentlemen present, understanding perfectly what was said to him, and replying intelligibly in return. No doubt seven or eight years may seem a long time to expend in teaching a child to speak and understand when spoken to; but it should at the same time be remembered that the other branches of education are being carried on at the same time, so that, although the money invested in this system before the child is fifteen years old is greater than in the other method, his condition, both mentally and socially, will compare very favourably with that of a child who, educated to use only the finger-alphabet in conversation, is isolated in life except in his intercourse with other mutes and those who have acquired their mode of speaking. The subject is one of much interest, and the system deserves a fair and full trial in this country. At present, the only public school where it is taught is at 164, Euston Road, which has been conducted by Mr. Van Praagh for three or four years. The progress which the children have already made affords very good opportunities for investigating the means employed in teaching mutes by the method which we have just described. It ought also to be made known that persons who have become deaf after they have talked naturally, may at any age be taught to converse by this method in a few minutes.

AN action brought against Mr. D. H. Watson of Stockton for alleged "maltreatment" of a lying-in woman, damages £2000, was tried this week in the Stockton County Court. The action failed, and the verdict was received with applause. We shall give further particulars from a short-hand report next week.

THE General Hospital at Dudley was formally opened last week by Lord Dudley at a public ceremonial, followed by a banquet. The buildings and land, valued at £30,000, are the gift of Lord Dudley; and an endowment of £20,000 is a legacy by the late Mr. Joseph Guest of Dudley.

DR. MAUNSELL of the Hokitika Hospital, New Zealand, furnishes a very admirable and valuable report. He specially calls attention to the necessity of establishing an asylum for chronic and incurable cases; and also of obtaining government subsidies for this most desirable object.

THE Quarterly Dinner of the Edinburgh University Club will be held at St. James's Hall Restaurant, London, on Wednesday, November 8th, Dr. Sieveking in the chair.

#### CHOLERA.

NEWS from Constantinople, dated October 13th, states that cholera was on the increase in Michalitz, near Broussa; and that it had newly broken out in Ushak and several villages in Asia Minor in the direction of Smyrna.

#### TATTOOED FROM HEAD TO FOOT.

THERE is now exhibiting in medical circles in Vienna a remarkable instance of tattooing of the whole body. According to his own account, the man, a Greek by birth, had been a pirate, and had also carried on brigandage on the continent. Seven years ago, he and five companions were taken prisoners by one of the wild tribes of Asia. Three of them were put to death; but this man, with two others, was preserved alive and literally tattooed over the entire body. The operation lasted two months, and was performed by six men, who each day operated on different parts of the body. The proceeding caused horrible pain; and his two companions died under the treatment. His body is covered from head to foot with delineations of men, animals, and fabulous things. The colouring material used for the figures appears to be indigo, the ground, especially on the chest and abdomen, being vermilion; here and there, about a line's breadth of the normal colour of the skin can be seen. The hands and the soles of the feet are coloured red, but have no figures. On the face and neck are inscriptions in characters resembling Arabic. The skin has the general appearance, to the sight and touch, of bluish-grey velvet. He attends the General Hospital in Vienna; and Professor Hebra, who showed him to his class a few days ago, has had him photographed in various attitudes.

#### THE BRITISH MEDICAL BENEVOLENT FUND.

TWENTY-TWO applications for assistance were laid before the Committee at their meeting on Tuesday last, and in eighteen of these grants were made amounting in the aggregate to £135. The Treasurer reported the receipt of a legacy of £500, free of duty, from the late Dr. George Cursham. This sum has, in accordance with the laws, been invested and added to the annuity fund. We regret to find that the Committee are unable, from want of funds, to increase the number of annuitants this year, there being as many as thirty candidates admitted as eligible who are eagerly awaiting their election.

#### FACILITIES FOR CRIME.

DR. STAMFORD FELCE has once more called the attention of the Registrar-General to the facility which some of his district registrars afford for deceptions and crimes by enrolling as "certified" deaths, deaths where the certificate is not signed by a registered medical practitioner. Major Graham observes that registrars are not provided with copies of the *Medical Register*, as to do so would involve too great an expense to Her Majesty's Government. We will not stop to discuss the two sides of this question, as to which it would even be possible to point out to Mr. Gladstone three solutions; but we will at once ask Major Graham to issue to his registrars directions to require that death-certificates shall be signed as ———, M.R.C.S., or otherwise, "registered". The only legally recognised right of any medical man to perform legal acts as such, is now based on his registration. If the registrars cannot ascertain registration otherwise, they can refuse to accept as a "medical certificate" a document which does not purport to be signed by a registered medical practitioner. The false pretence to be registered is a legal offence, and thus the Registrar would provide an easy and just safeguard, such as the law indeed evidently contemplates, by preventing unregistered and unqualified quacks of all kinds from imposing on the ignorant poor the belief that their sham titles are real ones. There is no doubt that the present facility with which the officers of the Registrar-General accept these sham titles as real, and valueless

statements as medical certificates, greatly encourages the present frauds on the people, and helps the lowest kind of quacks to continue to prey on those whom they deceive. Let deaths occurring under such circumstances be entered as uncertified, and something will be done to check fraud, and, we believe, also to give a warning as to crime—such as abortion, child-murder, and poisoning. Shortly, we hope, the legislature will prohibit the registration of uncertified deaths without further precautions than are at present taken.

#### MR. CHRISTOPHER HEATH ON CIRCULATION.

WE publish in another column a communication from Mr. Christopher Heath, relating to our summary of his recent correspondence concerning the excess of circulation of the BRITISH MEDICAL JOURNAL over that of any other medical periodical. Mr. Heath has clearly placed himself in a very unfortunate position, in which it does not appear that the only persons who could afford him the means of extrication have come to his assistance: these are the proprietors of the journal to which he is attached. In this position, we wish to extend to him every possible courtesy and consideration; and, but for the necessity of defending the interests which he has attacked, we should feel a sincere satisfaction in avoiding to make any addition to the pain which he must feel. We fear that his present communication only adds to the jeopardy in which he has placed his reputation for accuracy and discretion. His notion of what constitutes a public matter we pass without comment. On this occasion, he might naturally be expected to differ from us, and is fully entitled to the benefit of his individual judgment. We claim, of course, the same privilege. As to what he calls his "justification", it so imperfectly keeps the word of promise to the ear, and so completely breaks it to the sense, that only a fatal perception of the necessity of saying something can have induced a man of his ability to undersign such a document. It is not even the beginning of a justification, or any part or shadow or faint image of a justification. Mr. Heath makes certain verbal additions, which, he thinks, should have been included in our summary of this long correspondence. If these be read, it will be seen that they amount to nothing more than repetitions of his "belief". We did not use those words in our summary, because we at the outset very fully stated his incorrect belief, and because these particular phrases are obviously and absurdly incorrect; the contradictions of these exaggerations of his original error are, of course, implied in the contradiction of the greater error. Our publisher proved that the BRITISH MEDICAL JOURNAL has doubled its circulation in the last five years; that it has done this while the *Lancet* has either stood still or retrograded; and that the stamped circulation exceeded that of the *Lancet* last year by about two thousand copies a week. This year it exceeds it by more than that number. He further stated that the estimated total circulation of the BRITISH MEDICAL JOURNAL exceeds that of the *Lancet* or of any other medical journal. Mr. Heath stigmatised that statement as a dishonourable falsehood. Challenged by our publisher and by ourselves to prove that charge, he replies that he has no knowledge of the essential facts necessary for such proof. As far as the facts are concerned which affect this JOURNAL, he proves himself ill informed. He declared that, after the 30th of June, we should have to print five hundred fewer copies than before. He is informed that, on the contrary, we have had to print two hundred and fifty copies more than we were then printing. For his error he makes no apology. He now states that "the BRITISH MEDICAL JOURNAL circulates only among its own subscribers". Every journal circulates among those who pay for it. But, if by this sentence he means that the BRITISH MEDICAL JOURNAL circulates only among the members of the Association, that is a statement which is, if possible, more egregiously inaccurate than the former. Finally, he admits that he does not even now, several weeks after commencing this painful correspondence, know the circulation of the journal to which he is attached, and of which he has written so much. In that matter, then, we think that his proprietors have treated him very scurvily; and that he is an ill-used, and we cannot help saying also a very injudicious person. He should never have

written so positively—not to use a stronger word—about what he does not know; and he should either insist upon the facts being authenticated by the acceptance of the challenge of our publisher to submit the books of the two journals to a public accountant with a view to the publication of the relative figures, or he should make his apology and retire from what he must feel to be an utterly false position. If his faith were as robust as his courage, we think it clear that he would do so. With his private belief we have, of course, little to do; and, if it could add to his comfort to entertain the delusion that the journal in which he writes has a larger circulation than ours, we should be sorry to disturb it so long as it was confined to his own breast. But, as he observes, publishers and others may be induced, by his publicly clinging to that belief, to share his delusion; and that, as a matter of business, concerns the members of the Association to which he belongs. That is why we desire to dispel any delusion by the open and authenticated publication of the facts in the fair and honest manner suggested by our publisher's offer. Mr. Heath overlooks—or is not aware of—the fact that the stamp-returns do not represent the entire circulation of the *BRITISH MEDICAL JOURNAL*; inasmuch as, for years past, several hundred copies have been weekly distributed to subscribers and others in London by hand, not to mention the copies which are sold. A very small part of our circulation passes through the hands of the trade; for we have every reason to desire to save publishers' commissions, as far as may be. As to Mr. Heath's position and duty as a member of the Committee of Council, we have no doubt that he will fully consider that matter, and little fear but that he will arrive at a right conclusion. He evidently forgets that he referred to that position in his very first letter opening the correspondence. He has done his duty—perhaps rather overdone it—to the proprietors of the journal to which he is attached; and we entertain the opinion that, as his duty to the Association, he ought to insist on the facts being furnished which can alone repair the injury and affront which his first statements—made, as he confesses, without facts—were and are calculated to convey. He will, however, be the best judge whether he prefers to leave his statements unsupported; his affronts neither withdrawn, justified, nor excused; and his injuries unhealed by any kind of reparation. We have a much better opinion of his judgment and character than to suppose this. We believe that he has not yet done justice to himself in this matter. In any case, however, we feel sure that he is safe from the "personal abuse" which he seems unnecessarily to fear; and that, if final judgment be recorded against him, it will be with courtesy and regret, and without a shadow of personal ill-feeling.

#### HOSPITAL SUNDAY.

AT the annual meeting in connexion with the Hospital Sunday movement in Liverpool, it was stated that one hundred and ninety-five congregations co-operated in the effort, and that £4,869 was collected. The sum of £4,500 was distributed to the fourteen medical charities, leaving a balance of £140:7:1 to meet expenses and to be carried over. The collections next year will be made on January 14th. It was stated by the Mayor that the Corporation funds were so low, that he feared that they would be unable to make their usual contributions to the public charities next year. A similar collection was made at Newcastle on Sunday last. We do not know what amount was raised.

#### MEMORIAL OF MR. SOLLY.

A FUND is now being raised for the purpose of marking by some memorial the esteem and respect felt for the late Mr. Solly by his friends and students of St. Thomas's Hospital. Already upwards of three hundred pounds have been subscribed to the fund. At a meeting of the Committee on the 13th ult., it was resolved that the fund should be applied to the establishment of an annual prize of some shape bearing Mr. Solly's name; that a bust of him should be presented to the medical school of that hospital. Those desirous of subscribing to the fund may communicate with Dr. Rayner, Bethlem Hospital; or with Messrs. W. Anderson and W. W. Wagstaffe, St. Thomas's Hospital.

#### SUBCUTANEOUS DIVISION OF THE NECK OF THE THIGH-BONE.

ON Wednesday last Mr. W. Adams divided the neck of the thigh-bone subcutaneously at the Great Northern Hospital, in a case of bony ankylosis of the right hip-joint, with extreme deformity. The patient was a young man aged 18, who had suffered from fever (probably rheumatic) when eight years of age, and the joint afterwards remained contracted. Mr. Adams first made a punctured wound, a little above the top of the great trochanter, by an enlarged tenotomy knife, which was then passed directly down to the neck of the bone, and the muscles were freely divided and the capsular ligament opened. Mr. Adams then passed his small saw down to the anterior surface of the neck of the bone, and, cutting from before backwards, divided this structure. The division of the bone occupied seven minutes. After the neck of the bone had been divided, some resistance was still offered, apparently by some bone which had been thrown out in front of the joint. This had been felt at the commencement of the operation; but, on flexing the thigh, it rapidly gave way, and the limb then moved freely in all directions. Mr. Adams then divided the tendons of the rectus and adductor longus muscles, and also the tensor vaginae femoris muscle. The patient was put to bed with the limb in a much improved position. The details of the case will be given in a future number.

#### AMENDMENT OF THE LICENSING SYSTEM.

WE have already expressed the opinion that the first and most practical way of opposing the spread of brutalising intemperance amongst the poor, is to afford them the same facilities or inducements for avoiding resort to taverns and gin-palaces, and drinking in public-houses, as have been extended with the happiest effects to the upper classes. It is no longer necessary for the man of moderate means to go to the tavern to get his bottle of wine, or to enjoy what is known as moderate conviviality. With the habit of tavern-drinking among the better classes, the habit of intemperance has died out. Mr. Gladstone's bill for facilitating the introduction and sale of light wines and pure spirits has been a great temperance measure. The grocer is the natural enemy of the publican; and the practice of drinking what wine or spirits the consumer requires or desires at home, where inducements to restraint abound, instead of in the tap-room, where inducements to excess are always in operation, is the most potent means of attacking general intemperance among the lower or the higher classes. These arguments, which were placed before Mr. Bruce by the Parliamentary Bills Committee of the Association last autumn, have, we are glad to see, been adopted and advocated by an able correspondent of the *Times* of Oct. 26, whose arguments have been left unanswered. Let the poor man have the same facilities as the rich for comfort at home, but let the practice of drinking on the premises be restricted in them to the narrowest possible limits, and we believe that a severe blow will be struck at the habits of debased and destructive intemperance among the poor.

#### THE ELECTION OF GENERAL SECRETARY.

THE Committee of Council, at a full meeting held on Tuesday last, elected Mr. Francis Fowke, House Governor and Secretary of the General Hospital, Birmingham, as General Secretary of the Association. The Secretary will henceforth reside in London, and will give his whole time to the duties of the post, taking charge of the business of the JOURNAL office. There were, we believe, nearly 200 applicants for the vacant position, including a number of highly qualified candidates. The Committee of Council had previously appointed a subcommittee to facilitate the carrying out of the resolutions of the General Meeting at Plymouth; and this subcommittee had met both in Birmingham and London, carefully entered into the questions of business detail, and examined the testimonials of the candidates. The Committee of Council had before it the fullest information as to all the facts and details; and, on the recommendation of the subcommittee, approved and adopted a series of regulations for the improved conduct of business. The election of Mr. Fowke from among the large number of candi-

dates was almost unanimous. His qualifications were attested in the strongest manner by a large number of persons, including most of the best known names among the medical profession in Birmingham; and the testimony as to his energy and business capacity was especially strong. There is thus the fullest reason to anticipate that the wisdom of the course taken at Plymouth, and of the choice made by the Committee, will be amply justified by the event. The terms offered by the Association proved very attractive; and the Association will now have at its disposal, in the office of General Secretary, the services of a gentleman specially trained to business duties and of highly attested capacity, who will be able to devote his whole time to the conduct of its affairs. The reorganisation thus completed has involved, for the more active members of the Committee of Council, an amount of labour and anxiety, and an expenditure of time, and a number of distant journeys, during the last year, which have by no means appeared on the face of the facts. Their labour claims, however, the warmest recognition from the members of the Association; and in that, and the success of their efforts, they will find their best reward.

#### "MAYNE'S LEXICON" AND THE NEW SYDENHAM SOCIETY.

WE learn that the course of the Sydenham Society in reference to their announced new edition of Mayne's *Lexicon*, is not quite so clear as was expected. The edition, as published by Messrs. Churchill, is not yet exhausted; and there are other interests concerned besides those of the late Dr. Mayne's representatives, with whom alone the Society has thus far been in treaty. It would appear, therefore, that this valuable work is not likely to be issued in any other than its existing form for some time.

#### THE SURGICAL AID SOCIETY.

THE Annual Meeting of this Society was held at the Terminus Hotel, Cannon Street, City, on October 30th, 1871, at 3 P.M., Roger Eykyn, Esq., M.P., in the Chair. The Ninth Annual Report of the Committee was read, showing that 5,550 cases have been relieved since 1863; and 1,465 of these during the past year. Of which number, 506 were men, 692 women, 153 boys, and 114 girls. Nearly 6,000 appliances, including 286 elastic stockings and leather knee-caps, 1,723 trusses and belts, and 577 leg-instruments have already been supplied by the Society. Votes of thanks were given to the Treasurer, William Gray, Esq.; and to the Surgeons, Messrs. Allingham and Davy, for their services rendered to this important charity.

#### FORGED DIPLOMAS.

A STRIKING illustration of the want of a public prosecutor has just occurred, and we think that the profession and the public generally will give due credit to the authorities of the College of Surgeons, and the respectable tradesman by whom the transaction was brought under the notice of the College. A few days ago, a law-stationer, of Holborn, received a visit from a "doctor," who wanted his name entered in a diploma from New York, in which the names of the examiners appeared, with the large seal of the College affixed. After his visitor had left, however, the stationer thought there must be something wrong, and at once called on Mr. Trimmer, the Secretary of the College of Surgeons. Here it was seen that the signatures were lithographed facsimiles, touched up with ink. Mr. Stone, accompanied by his informant, called on Mr. Moran, the Secretary to the United States Minister, and explained all the circumstances, pointing out not only the injury inflicted on the New York College by the sale of a false diploma, but also on the public generally, adding that an Institution in Scotland had been so imposed on by a non-professional person who had purchased this spurious document, as to grant him its diploma, in virtue of which he was now seeking admission *ad eundem* to an English Institution. Mr. Moran regretted that all he could do was to write an account of the circumstance to New York. Mr. Stone wished him to impound the document; but this, he said, he could not do, although it is plain that a forged note for the payment of a certain number of dollars would at once be seized, and the forger sent to the nearest police court. Mr.

Stone then called to see the detectives at Scotland Yard who had so successfully apprehended the Du Brange gang, prosecuted recently by the College to conviction; they were both absent. As a last resource, Mr. Stone called at Bow Street to ask the advice of Mr. Burnaby, the chief clerk; here still greater difficulties were pointed out. Finally, it occurred to Mr. Trimmer to have the diploma, seal, etc., photographed, and copies distributed to all institutions in the United Kingdom granting diplomas or licenses, and a copy sent also to the authorities of the institution upon whom the forgery has been made to take such action as may be considered necessary to stop the nefarious proceeding. The remarkable difficulty experienced in taking steps to arrest a forgery aiming at the security of life, is noteworthy when we recall the facility which would have been found had the forgery affected the disposal of a sum of money, no matter how small. It is certain that this is not the only forged diploma of the kind in existence; and we are not without hope that means will yet be found to convict and punish the persons concerned in this fraud, now that the clues are in the hands of the authorities. It is certainly a case which ought to be brought to the notice of the Home Office.

#### THE OBSTETRICAL SOCIETY OF LONDON.

AT the meeting of the Obstetrical Society on Wednesday, a paper by Dr. Conrad, on Prolapse of the Female Genital Organs, gave rise to a most interesting discussion. The author contended that the vagina was first in fault, and then subsequently the uterus. Dr. Barnes asserted that prolapsus never occurred in the multipara; that rupture of small vessels in the cervix during labour, with oedematous condition following, and retarded involution, leading to ultimate hypertrophy, was the primary condition; the vagina, at a later stage, producing irritation and keeping up the hypertrophy. In old women, the uterus prolapsed from absorption of the pelvic cellular tissue around the vagina, which thus weakened the uterine support. Mr. Spencer Wells, on the other hand, thought that prolapse of the anterior vaginal wall was the first step in the process, and that tightening the ruptured perineum was the first step in the operative direction; but removal of a portion of the cervix was also essential. Dr. Braxton Hicks considered that, when the uterus descended, it acted as a foreign body, set up reflex irritation, and the vagina was pushed down; the difficulty in defecation and position of the bladder tending to increase the mischief. Several other Fellows of the Society also took part in the discussion.

#### THINGS OLD AND NEW.

WE are indebted to the accomplished pen of Dr. Cholmeley for some interesting details in the history of therapeutics. In his annual oration before the Medical Society of London just published, he has disinterred from the minutes of this aged Society (which will shortly celebrate its centenary) some valuable records of therapeutic practice in the commencement of this century. Among the subjects referred to are, the value of turpentine as an internal styptic (1799); the use of savin for keeping open blisters (Hurlock, 1797); Fowler's solution of arsenic in ague and intermittents (May, Bradley, and Sims, 1790), and in hemiplegia (Lettsom and Adams, 1813); nitrate of silver in epilepsy and chorea (Sims, 1794 and 1802); digitalis in dropsy (1790), in hooping-cough (Leese, 1806), and in palpitation of the heart (Andre, 1810); transfusion after exhaustive hæmorrhages (1818 and 1825); paracentesis thoracis (Dr. Davies, 1830); tracheotomy in croup (1817). In 1815, Dr. Lettsom reported that, during a professional visit to Hertford, he found "that in that neighbourhood carbonate of ammonia was considered quite as a sovereign remedy in scarlatina. Physicians there were astonished at its success. It was given in five-grain doses every four or six hours." Again, in 1816, Mr. Edwards said "that he had always given the carbonate of ammonia in scarlatina, and never knew it fail. He gave five grains every four hours; to an infant or child, two grains. It generally subdued the fever in forty-eight hours, after which he gave bark." This, therefore, is one of the rediscoveries of medicine. Another is the opium treatment of rheumatism. In 1812,

Mr. Bateman reported that "he had seen Dr. Pearson at St. George's Hospital use large doses of opium with diluents and doses of salts, with good effect, in acute rheumatism;" and Dr. Lettsom in 1814 reported that he had lately given opium very freely in cases of acute rheumatism, after having well cleared out the bowels, with infinite advantage. Yet another "modern mode of treatment", in which our ancestors at the Medical Society of London had the start of us, was the treatment of dysentery by ipecacuanha, which was employed and warmly recommended, after the now prevalent mode of administering, by Mr. Balmain and Mr. Wentworth, in January 1797. It is interesting to notice, as bearing upon the much debated question of change of type, that the carbonate of ammonia and bark treatment of scarlatina was carried on side by side with the treatment by venesection; for Mr. Houghton of Huddersfield reported at the same meeting that he in all cases bled once or twice to six ounces, and gave salines; and that he, too, was uniformly successful. It will be seen that Dr. Cholmeley's skilful and well considered search in the minutes of the Medical Society have been far from fruitless; and we recommend his *brochure* as one of greater interest than anniversary orations of the kind are usually found to be.

#### THE MEDICAL SCHOOL OF LISBON.

THE session of this school commenced on October 5th. As is his custom on such occasions, King Luis was present, and, in reply to an address from the director of the school, expressed the pleasure which he felt in taking part in the proceedings, and his interest in the promotion of education. The prizes having been distributed, Senhor Magalhães Coutinho, director of the school, delivered an introductory address. He noticed the tendencies of modern medicine, and pointed out the reforms which were necessary in the Lisbon school. The custom of some professors, to clothe their ideas in eloquent language adorned with the flowers of rhetoric, in place of giving simple descriptions of the results of observation and experiment, was censured. Their pupils, he said, in place of solid instruction, only got from such teaching incomplete or erroneous ideas, and a vain verbosity, which is always the cloak of ignorance. The lecturer expressed his belief that the prosperity of the school would be assured by the development of practical instruction. By this he did not mean such as would enable the student to dissect out artistically an aponeurosis or make a preparation of the internal maxillary artery; pathological anatomy, microscopy, chemistry, physiology, and toxicology, must all be studied practically—and for this purpose there must be a sufficient number of demonstrators. The amount of scholastic teaching, he thought, might be somewhat reduced, so as to give the students more time for clinical instruction. The address was altogether excellent; and the Lisbon school of medicine may, we think, congratulate itself on having as its director such a man as Senhor Magalhães Coutinho, who evidently understands clearly what reforms are required in the institution to which he belongs, in order to enable it to hold its ground among the medical schools of the present day.

### SCOTLAND.

THE Senatus of the University of Edinburgh, since the interlocutor of Lord Gifford, mentioned in last week's JOURNAL, have resolved to relieve the Managers of the Royal Infirmary from the bargains entered into between both parties.

#### ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

At the annual meeting, held on October 18th, the following office-bearers were elected for the ensuing year. *President*: W. Walker. *Secretary*: James Simson, M.D. *Treasurer*: John Gairdner, M.D. *Librarian*: A. Inglis, M.D. *President's Council*: Andrew Wood, M.D.; R. Omond, M.D.; J. Dunsmure, M.D.; J. D. Gillespie, M.D.; James Spence; H. D. Littlejohn, M.D.; J. Gairdner, M.D. *Examiners*: A. Inglis, M.D.; R. Omond, M.D.; J. Dunsmure, M.D.; P. D. Handyside, M.D.; J. D. Gillespie, M.D.; H. D. Littlejohn, M.D.;

P. H. Watson, M.D.; D. Wilson, M.D.; John Smith, M.D.; A. Robertson, M.D.; J. Bell, M.D.; T. Annandale. *Assessors to Examiners*: J. S. Combe, M.D.; William Brown; J. Spence; J. Simson. *Conservator of Museum*: J. B. Pettigrew, M.D. *Assistant to Conservator*: J. Grandison.

#### THE SCOTCH SCHOOLS OF MEDICINE.

THE winter session at the University and Surgeons' Hall, Edinburgh, commenced on Wednesday with an introductory address at the University by the Principal, Sir Alexander Grant, Bart.; and at Surgeons' Hall by Mr. Annandale. At Aberdeen, the session was opened on Thursday; at the University of Glasgow on Tuesday, with an introductory address by Professor Dickson; and at Anderson's Institution, Glasgow, on the same day, with an inaugural address by Professor Bischof, the newly-elected Professor of Technical Chemistry.

#### THE SENATUS OF THE UNIVERSITY OF EDINBURGH AND THE LADY MEDICAL STUDENTS.

ON Monday, the Senatus had under their consideration the following communication from the Secretary of the Executive Committee for securing a complete Medical Education to Women in Edinburgh:—"That the Secretary be instructed to write to the Senatus, in view of their approaching meeting, to state that, in the event of special lecturers being appointed by the University to give qualifying instruction to women, the Committee are willing to guarantee to them the payment of any sum that may be fixed by the Senatus for their remuneration, in case the fees of the ladies are insufficient for that purpose; and that, if necessary, they are willing further to undertake to provide such rooms and accommodation as may be required for the delivery of the said lectures, if it should be found absolutely impossible for the University to provide space for that purpose." After some discussion, the Senatus resolved, by a majority, not to recommend to the University Court any measure by which the ladies might be enabled to complete their education.

### IRELAND.

THE Guinness Dispensary, Dublin, is now completed.

#### SMALL-POX IN DUBLIN.

SMALL-POX is steadily increasing in Dublin: the fatal cases, however, are limited to those who have not been vaccinated, or those in whom the marks of vaccination are doubtful. It is sad to think that with six months' notice no effort has been made by the sanitary authorities either to provide conveyances or hospitals for cases of this disease. The so-called Sanitary Committee of the Corporation do worse than nothing. In the *Irish Times* of October 28th we observe the following:—"The prompt and judicious conduct of Sanitary Sergeant Dagg, 8 D, in preventing the spread of infectious disease by promoting the interment of a child of destitute parents, who died of small-pox, having been brought under the notice of the Public Health Committee of the Corporation, they unanimously voted him a reward, and directed that his conduct should be recommended to the favourable consideration of the Police Commissioners." It is asserted that some of the worst tenements are either owned, farmed out, or the rents collected, by ex-policemen. A doubt was thrown out by *Saunders' News Letter* as to the existence of "The Public Health Committee of the Corporation", and Mr. Norwood came to the rescue; his figures, however, are not more convincing than those of Dr. Mapother. Disinfection, as at present carried out in Dublin, consists in a "couple of men coming with a couple of brushes and a bucket of whitewash and giving a lick and a promise": indeed, Mr. Norwood's figures satisfactorily prove that it could not be otherwise at the price; for, if his figures be correct, one halfpenny each would exceed the expenditure for cleansing, disinfecting, and inspecting, all the nuisances to which he alludes.

## ASSOCIATION INTELLIGENCE.

### SOUTH WALES AND MONMOUTHSHIRE BRANCH: ORDINARY MEETING.

THE next Ordinary Meeting of this Branch will be held on Tuesday, November 7th, at the Town Hall, Cardiff, at 1.30 P.M. The Council will meet at 12.30 P.M.

The dinner will take place at 4 or 5.30 P.M., as may be found most convenient; and members may introduce friends to the meeting and dinner. Tickets, 6s. 6d. each.

Members intending to read papers or notes of cases are requested to communicate the titles thereof as soon as possible to one of the Honorary Secretaries.

All members who purpose joining the dinner, will oblige by communicating their intentions to one of the Honorary Secretaries.

ANDREW DAVIES,  
ALFRED SHEEN, M.D., } *Honorary Secretaries.*

October 30th, 1871.

### BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

THE next ordinary meeting of this Branch will be held at the Council Rooms of the Midland Institute, Birmingham, on Thursday, November 9th, at 3 P.M.

T. H. BARTLEET, *Honorary Secretary.*

Birmingham, November 1871.

In the report of the last meeting (BRITISH MEDICAL JOURNAL, October 28th), the names of the following gentlemen, elected members of the Branch, were accidentally omitted: Mr. T. Buxton, Fazeley; Mr. E. Bicknell, Coventry; Dr. Newman, Alrewas; and Dr. Torrance, Dunchurch.

### METROPOLITAN COUNTIES BRANCH.

A SPECIAL General Meeting of this Branch will be held at 37, Soho Square, on Tuesday, November 14th, at 4.30 P.M., to take into consideration certain alterations in the Laws of the Branch, proposed by the Council.

A. P. STEWART, M.D.  
ALEXANDER HENRY, M.D., } *Honorary Secretaries.*

London, November 1st, 1871.

### SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT MEDICAL MEETINGS.

THE November meeting of the members of the above District will be held in the afternoon of Friday, November 24th, at Brighton; Dr. ALFRED HALL in the Chair.

All members of the South Eastern Branch are entitled to attend, and to introduce professional friends.

Gentlemen desirous of making communications to the meeting, will oblige by giving me an early intimation, in order that notice thereof may be included in the circular which will convene the meeting.

THOMAS TROLLOPE, M.D. Cantab., *Hon. District Secretary.*

35, Marina, St. Leonard's-on-Sea, November 1st, 1871.

### REPORT OF MEETING OF COMMITTEE OF COUNCIL:

*Held in Birmingham, October 31st, 1871.*

PRESENT:—W. D. Hubbard, Esq., F.R.C.S., in the Chair; Mr. Baker, Dr. Paley, Mr. Bartleet, Dr. Bryan, Mr. Board, Dr. Chadwick, Mr. Clayton, Mr. Andrew Davies, Mr. Fowler, Mr. Reginald Harrison, Mr. Christopher Heath, Mr. Hodgson, Mr. Nicholson, Dr. Phillips, Dr. Wilson, Mr. Heckatt Smith, Mr. Southam, Dr. Steele, Dr. Underhill, Dr. Edw. Waters (Chester), Mr. Wheelhouse, Dr. Wilkinsons, Mr. Wood, and Mr. Williams (Secretary).

a. The following resolutions were adopted.

1. That the next annual meeting be held on the 6th, 7th, 8th, and 9th of August, 1872.

2. That there shall be two addresses—one in Medicine, and one in Surgery.

3. That Dr. Fleming be appointed to deliver the Address in Medicine.

4. That Mr. Pemberton be appointed to deliver the Address in Surgery.

5. That the Report of the Branch Secretaries' Subcommittee now

read by Mr. Hodgson, be received, printed, and circulated forthwith among the members of the Committee of Council, and taken into consideration at the next meeting of the Committee of Council.

6. That the subject for competition for the Hastings Medal for 1873, be the Pathology and Treatment of Ovarian Diseases.

7. That Mr. F. Fowke be elected General Secretary of the Association, and Manager of the JOURNAL office.

T. WATKIN WILLIAMS, F.R.C.S., *General Secretary* (pro tem.)

13, Newhall Street, Birmingham, November 1st, 1871.

### SHROPSHIRE ETHICAL BRANCH: ANNUAL MEETING.

THE annual meeting of the Shropshire Ethical Branch was held at the Lion Hotel, Shrewsbury, on Friday, October 6th, at 1 P.M.; the President, A. G. BROOKES, Esq., in the chair. Nineteen members were present.

THE PRESIDENT briefly addressed the meeting, and, among other subjects, suggested the desirability of quarterly meetings being held in selected districts of the county, for the discussion of papers and questions affecting the general interests of the profession.

The following resolutions were passed unanimously.

*Minutes of General Council.*—"That the Minutes of the last general meeting be affirmed."

*Vote of Thanks.*—"That the cordial thanks of the meeting be given to the late President, Vice-presidents, Council, and Honorary Secretaries, for their valuable services during the past year."

*Election of Officers.*—"That J. W. Procter, Esq., be elected President, S. Betton Gwynn, and F. H. Hartshorne, Esqrs., Vice-presidents, and the following gentlemen members of the Council for the ensuing year, in the place of those who retire by rotation:—James Bratton, Esq., Henry Fenton, Esq., S. B. Gwynn, Esq., E. T. D. Harrison, Esq., and J. R. Humphreys, Esq."

*Representatives of Branch in General Council.*—"That, in accordance with the eighth general law of the Association, A. G. Brookes, Esq., J. W. Procter, Esq., J. R. Humphreys, Esq., and Dr. Jukes Styrap, be the representatives of the Branch in the General Council for the ensuing year."

*Representative of Branch on Parliamentary Committee.*—"That the President, A. G. Brookes, Esq., be the representative of the Branch on the Parliamentary Committee."

*Thanks to the President.*—"That the cordial thanks of the meeting be given to the President for the ability and courtesy with which he has conducted the business of the meeting."

*Communications.*—A case of Tumour of the Uterus, and one of Punctured Wound of the Lung, were communicated by Mr. J. R. Humphreys; and two papers on a Cold and its Cure, and a Specific for Ptyalism, were read by Dr. Styrap.

The announcement by Dr. Styrap that the oldest living member of the Branch—W. Thurfield, Esq., of Bridgnorth (one of the few remaining original members of the Provincial Association)—was most reluctantly about to retire from the Association, in consequence of continued ill-health and advanced age, was received with very general regret, and warm expressions of sympathy and esteem.

*Dinner.*—At 4 P.M., thirty-four gentlemen (twenty-eight members and six visitors) sat down to an excellent dinner, the President in the chair, supported by the Rev. J. Yardley, Rev. H. W. Moss, and the Rev. W. Bromley; the vice-chair being filled by J. W. Procter, Esq., President-elect. During the dinner, and after each toast, appropriate selections of music from Auber, Donizetti, Flotow, Mendelssohn, Rossini, and others, were played by a band of musicians under the leadership of Mr. Hulley, of Liverpool, which materially contributed to the enjoyment of a very pleasant evening.

### READING BRANCH: ANNUAL MEETING.

THE sixteenth annual meeting of this Branch was held in the library of the Royal Berkshire Hospital, on July 5th; GEORGE MAY, jun., Esq., President, in the chair.

*New Officers and Council.*—The following were chosen. *President-elect:* R. C. Shettle, M.D. *Members of Parliamentary Committee:* N. Crisp, Esq. *Representative in General Council:* J. Workman, Esq. *Council of Branch:* N. Crisp, Esq.; I. Harrison, Esq.; E. Wells, M.D.; R. T. Woodhouse, M.D.; J. Workman, Esq.; W. B. Young, Esq.; with the President and Secretary. *Honorary Secretary:* R. C. Shettle, M.D.

## REPORTS OF SOCIETIES.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, OCTOBER 24TH, 1871.

T. B. CURLING, Esq., F.R.S., President, in the Chair.

## LARGE BILIARY CONCRETION IN THE ILEUM.

BY F. LE GROS CLARK, F.R.C.S.

THE author gave the details of a case occurring in a patient aged 58, who was seized with abdominal pain and bilious vomiting, accompanied by constipation. A hard tumour was felt in the right hypochondrium. There was no abdominal tenderness or distension. On the eleventh day, the vomiting became stercoraceous. Two days later, the bowels were open and the vomiting ceased until ten days later, when it recurred, and continued at intervals during a week. For three weeks after this time, the bowels acted daily, and there was no sickness. The patient was then seized with severe abdominal pain and vomiting; the abdomen was tender, especially over the region of the cæcum, where a hard tumour could be felt. Death took place two months from the commencement of the first attack. At no period of her life had the patient suffered from jaundice. The *post mortem* examination revealed the existence of extensive peritonitis. Two large gall-stones occupied the ileum close to the valve. An ulcerated opening in the small intestines had permitted the escape of several small gall-stones into the peritoneum. The gall-bladder was healthy; there were no adhesions between it and any portion of the intestines. There was no trace of any ulceration either in the gall-bladder or in the neighbouring intestines. The concretions measured one inch in length and four inches in circumference. They seemed moulded to the shape of the ileum. On examination, it was found that the stones were composed of ninety-five per cent. of cholesterine, and that nothing had been added to them in the intestines. The gall-ducts were dilated and thickened. The author drew attention to the singular absence of any proof that these concretions had passed by ulceration from the gall-bladder to the abdomen, though this is the only way in which such large bodies could have entered the intestines.

MR. DE MÉRIC asked what diagnosis had been arrived at in this case. He had seen a case in which similar symptoms were present, but in which no *post mortem* examination was made. No positive diagnosis was arrived at; but the symptoms preceding death were those of intestinal perforation. The patient sat up in bed, and suddenly died.—DR. STEWART some years ago saw a patient in the Middlesex Hospital, who had for about a week before death obstinate stercoraceous vomiting. A round smooth gall-stone, as large as that described by Mr. Clark, was found in the upper part of the ileum. The calibre of the intestine above the gall-stone was of ordinary size; but the bowel had contracted on the calculus and was much narrowed below. As far as he remembered, there were distinct marks of ulceration having taken place between the gall-bladder and the bowel. He had believed it impossible for gall-stones of such large size to pass through the ducts. But, the year before last, he was called to a lady who belonged to a family very subject to liver-affections, especially gall-stones. She had long had hepatic dyspepsia, and was seized with severe pain, which lasted some hours; after this there was partial ease, and then intense suffering during ten hours, followed by sudden and complete relief. The next day, he found that she had passed a round biliary calculus as large as a pigeon's egg. There were no symptoms of perforation of the bowel; and he thought that the calculus could scarcely have passed into the intestine in any other way than through the ductus communis choledochus.—DR. HABERSHON saw some years ago a case similar to Mr. Clark's, in which, after much difficulty, a wrong diagnosis was arrived at. The patient was a lady aged more than 50, who had severe pain, and bilious vomiting, without much tenderness. Death, preceded by great prostration, took place on the tenth day. A large gall-stone was found in the jejunum. There was no peritonitis. Adhesions existed between the gall-bladder and the intestine, but he could not make out that there was any communication between them. The patient had had no stercoraceous vomiting, because the obstruction was seated too high up.—MR. LE GROS CLARK had arrived at the diagnosis in his case rather by exclusion than in any other way. Whatever the cause of obstruction was, it did not produce inflammation. There was no evidence of twisting of the bowel or of malignant tumour. In the absence of jaundice or of any history of this condition, it did not occur to him to suspect the presence of a gall-stone.

## ON ETHER AND CHLOROFORM AS ANÆSTHETICS.

BY J. WARRINGTON HAWARD, F.R.C.S.

The paper commenced by stating that, it having been suggested to the author that the statements of Dr. Bigelow and other American sur-

geons showed that ether as an anæsthetic had been to our detriment neglected, he had, during the past year, practically investigated the subject, and had arrived at the conclusion that ether was, for several reasons, to be preferred to chloroform. Of these reasons, the strongest was the greater safety of ether; for by using it the chief, and in skilled hands probably the only, cause of fatal cases of chloroform-inhalation was excluded—*i.e.*, paralysis of the heart; ether being a stimulant to the heart's action, and uniformly improving the pulse. The second was that ether, from its stimulant quality, was antagonistic to the effects of the shock of an operation, which the author maintained, and quoted cases to show, was not abolished by rendering the patient insensible. A third was the greater liability of chloroform than ether to produce after-sickness. The principles and mode of administering ether were then described, and it was shown that if these were attended to, the production of anæsthesia by ether was as easy and certain as by chloroform, and required but little more expenditure of time or the drug. The only cases to which ether was not so applicable were operations upon the mouth, in which an inhaler could not be used, and where it was necessary to re-administer the anæsthetic as rapidly as possible without an inhaler. There were two appendices to the paper: the first consisting of a table of fatal cases of chloroform; the second, of a table of ninety-seven cases in which the author had administered ether, including amputations, excisions, perineal section, lithotomy, lithotripsy, staphylophary, operations on vesico-vaginal fistulæ, ligature of piles, and other operations. Especial note was taken of the occurrence of after-sickness, and the only approach to it was that in one case, after an operation for recto-vesical fistula, the patient vomited once, an hour after the operation.

THE PRESIDENT remarked that the author had omitted to notice the recommendation of the Committee of the Royal Medical and Chirurgical Society, to mix chloroform and ether.—MR. SPENCER WELLS thought that there were grounds for not carrying out this recommendation. In Vienna, where the plan of mixing chloroform and ether had been tried, it had been found that the patients first got the effects of the ether (the lighter fluid), and were then suddenly overpowered by the chloroform. He had long felt that there were serious objections to chloroform in operations involving the abdomen, on account of the persistent vomiting which was liable to follow its administration. He had, following the example of Dr. Keith of Edinburgh, given ether in some cases; but good ether was scarce, and the diffusion of the vapour through the air gave rise to inconvenience. After four years' experience, in more than three hundred cases, he had found bichloride of methylene to possess great advantages over both ether and chloroform. It was safer than chloroform; and after-sickness was rare. It might be administered from a graduated bottle, by having air forced through it by means of bellows. About four deaths had been reported to have followed its use; while, from the quantity sold, it was estimated that it had been given in 50,000 or 60,000 cases. Perhaps, however, even a better anæsthetic than the bichloride of methylene would yet be discovered.—DR. W. H. DAY gave an account of the characters of bichloride of methylene, as described by Dr. Richardson. It produced less sickness than chloroform; and the patients recovered more quickly from the anæsthesia which it produced—the agent being readily eliminated. For an operation lasting half an hour, three drachms of the bichloride of methylene were generally sufficient.—DR. C. KIDD preferred administering ether and chloroform separately. Thus it proved a good plan to place the patient at first well under the influence of chloroform, and continue the anæsthesia with ether in a separate inhaler, especially if the pulse became weak from shock or bleeding. Ether alone was very tedious; three or four ounces of chloroform would do as much as almost a pint of ether. As to the pulse, he agreed with Lister that it was very little influenced by chloroform. Sabarth gave thirty-six deaths under ether, so that it was not entirely devoid of danger. As to bichloride of methylene, it was suitable for short operations, but for long operations he considered it dangerous.—DR. SANSOM said that there were not sufficient data for estimating the relative dangers of chloroform and ether. The statistics as to chloroform differed widely; some giving the deaths as one in 16,000, and others as one in 2,500. The rate of mortality from ether was also variously given; but there was sufficient to show that it was not absolutely safe. Chloroform was more manageable than ether; on account of its nauseousness, many persons could not tolerate the latter. The danger of chloroform, in his opinion, lay in its diminishing the power of the circulation. From experiments which he had made, he agreed with Mr. Wells as to the effect of mixtures of ether and chloroform. When, however, chloroform was mixed with alcohol, it was not merely diluted, but its volatilisation was retarded, and a more free admixture of air was allowed. In many cases, a small quantity of morphia might be injected hypodermically, and then a smaller amount of chloroform would be required.—MR. HOLMES had tried ether some

years ago. He did not think that there was any difficulty in bringing patients under its influence, though it required about twice as much time as chloroform. There was no necessity for any diffusion of the vapour in the room; the window might be kept open. The chief reason why he abandoned the use of ether was that, when given by a sponge (as was ordinarily the case) it produced asthenic congestion and convulsive movements, especially in patients addicted to drinking. It was useless to imagine that a perfectly safe anæsthetic could be found. As to the statistics of death after the use of anæsthetics, these were of no use, unless it were shown in each case whether the agent was administered judiciously or injudiciously. If ether were given in a proper manner, there was no objection to it, and no inconvenience of importance attended its use.—Mr. R. B. CARTER had inhaled ether experimentally in 1848, and remembered that the taste of it remained for two or three days.—Mr. C. HUNTER agreed with Dr. Sansom that the danger with chloroform arose from its effect on the heart. If morphia were injected, it was necessary to look to the lungs as much as to the heart.—Mr. CLOVER was at University College Hospital when ether was first used there by Mr. Liston. He remembered that there were many cases of sickness after its use; and he had not found it so free from this result as had been alleged. It was difficult to breathe ether freely, on account of its pungency. Statistics were not trustworthy; and it must be remembered that cases in which chloroform was given in midwifery (its full effect not being produced) were not fairly comparable with those in which it was given for the performance of great operations, such as lithotomy. Much would depend, also, on the distance from the face at which chloroform was given. If the inspired air contained more than five per cent. of the vapour, there was marked tendency to produce death by syncope.—Mr. HAWARD having replied, the meeting adjourned.

#### ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

SATURDAY, OCTOBER 21ST, 1871.

R. DRUITT, M.D., in the Chair.

MR. GARDNER BROWN exhibited and explained a new Self-acting Disinfectant for Water-closets, etc., lately invented by him. He explained how the apparatus was self-acting, how the supply of carbolic acid or other disinfectant used was regulated, and by what contrivance economy and efficiency were secured.—Dr. STEVENSON believed the invention a very useful one.

Mr. LITTLE read a paper on the Intimate Relation between Defective Ventilation and the Mortality from Tubercular Diseases, Convulsions in Children, Teething, Atrophy and Debility, with a few practical suggestions. Hitherto the local boards had bestowed their attention on epidemic diseases, but had not given that attention to the prevention of consumption and its allied diseases that their importance demanded. He next dwelt on the importance of fresh air, and the lamentable ignorance prevailing, not alone among the poor, with respect to it. The appalling mortality among young children he attributed in great measure to neglect in this respect. For the poor, it was almost impossible to get pure air while they were compelled to inhabit their present wretched tenements. He regretted that little had been expended in amending this condition. How people afflicted with bad health in these close dens were benefited in health the moment they were removed to places in proper sanitary condition, was shown by the marked superiority in the health of prisoners compared with that of the surrounding population. He was lately invited to visit the training-ship *Goliath*, moored in the river off Grays, Essex. The boys were the children of pauper parents, and had been transferred to the ship for the purpose of being trained for Her Majesty's Navy. The register of their height, weight, and breadth of chest when received on board, when compared with what it was at the time of his visit, showed a remarkable increase in all these respects. Moreover, the sullen and downcast looks had given place to an expression of intelligence and cheerfulness. Mr. Little next spoke of the means of preventing the evils of overcrowding. The Medical Officers of Health ought to do their utmost to prevail on Boards to put into execution the existing laws. In the long run their very persistency must have its effect; and with regard to the building of unhealthy houses in the future, an opportunity was afforded of remedying defects in the present law when the New Building Bill should come on next session. He concluded by urging the Association to use its utmost exertions towards procuring the insertion of effective sanitary clauses.—Dr. LIFE suggested that the space required in front and rear of premises ought to depend on the height of the boundary walls. He considered that the Peabody and other such funds would have been better employed in sweeping away unhealthy property.—The Rev. Mr. COHEN said it was hard to call on the ratepayers to pay for people who would

do nothing to help themselves. The poor could not be prevailed upon to open their windows; they needed to be taught the benefits of ventilation.—Dr. SUTTON included insanity among the diseases arising from close and foul air, and showed the connection existing between phthisis and insanity.—Mr. GLADDEN would not have the owners of condemned property to bear all the loss, nor the ratepayers to pay full compensation; some middle course ought to be adopted.—Mr. FINLAY thought that care should be taken that no new buildings should be erected under unsanitary conditions.—Dr. HARDWICKE suggested the building of dwellings after a system which he had seen working well in Picardy. A manufacturer there had built huge blocks of tenements for his work-people; these were kept perfectly clean, not by the people themselves, but by servants specially appointed for that purpose.—The PRESIDENT remarked that, while the inordinate greed of landlords showed an unhealthy condition of the public conscience, the permitting such a state of things to exist argued great ignorance and stupidity on the part of ratepayers. Landlords for the sake of gain built houses that evidently undermined the health of the tenants, and made them a burden to the ratepayers. Why did not the latter take steps to prevent such proceedings?—Mr. LITTLE having replied, the meeting closed.

## SPECIAL CORRESPONDENCE.

### VIENNA.

[FROM OUR OWN CORRESPONDENT.]

*Case of Ovariectomy by Billroth.—Remarkable Case of Aneurism.—Local Causes of Lung-Disease.*

PROFESSOR BILLROTH has apparently quite overcome the prejudices against him as a Prussian. He is an unostentatious but most effective operator. The success in ovariectomy in Vienna has, until recently, been most limited; but some months ago Billroth determined to try vigorously to alter this state of matters, which if it had continued much longer would have removed this operation from the list of justifiable measures. By selecting his patients with great care the last six cases have been perfectly successful.

A very interesting case of aneurism occurred in Billroth's wards lately. The man complained of dyspnoea, but no signs of aneurism could be discovered. At last his dyspnoea became so intense that tracheotomy was resorted to, but the ordinary short cannula gave no relief. A much longer cannula was tried, and its insertion was opposed by a soft obstructive body. The breathing was relieved on the cannula being passed beyond this, but the difficulty in swallowing was unaltered. Aneurism was diagnosed in spite of the absence of all physical signs; and at the *post mortem* examination a sacculated aneurism at the commencement of the descending aorta was found, with a pouch extending betwixt the trachea and the gullet.

The weather here is eminently variable and trying to all lungs; and, as tuberculosis is not a disease *sui generis*, these repeated variations of temperature are provocative of much lung-mischief, which develops into tubercle. There is nothing markedly strumous in the appearance of the people to explain the fact of the excessive amount of pulmonary phthisis; it is a question of simple provocation. Already on a cold day stoves are lighted, and the temperature of the room reminds one of a Turkish bath; then without respirators the people pass into the cold air back and forwards frequently and repeatedly. The other night in a restaurant I counted seventy-seven persons seated, ten gaslights, and a sprinkling of waiters, in a room about eighty feet long and containing about 20,000 cubic feet of air. There was only one ventilator, which contained six triangular spaces about the size of the triangle which constitutes Mr. Bass's trade-mark. It was intensely cold for the time of year, and not one who went out had either respirator or other means to modify the temperature of the outside air. Nature has taken some pains to render Vienna liable to tubercle, but the habits of the people have supplemented what was wanting to insure its prevalence.

DONATIONS, BEQUESTS, ETC.—Mr. James Hatton has given £5000 to the Warrington Dispensary.—The Goldsmiths' Company have given £100 to the National Sanatorium, Bournemouth.—The General and the Queen's Hospitals, Birmingham, have each received £100 under the will of Mr. Thomas Tonks.—The General Hospital, Birmingham, has become entitled to £100 under the will of Mr. J. Evans, Moseley.

## CORRESPONDENCE.

## HER MAJESTY'S RECENT ILLNESS.

SIR,—A statement having been widely circulated to the effect that the Queen's recent illness was the result of revaccination, I trust you will, by inserting this letter, permit me to give the most unqualified contradiction to the report. There is not a shadow of foundation for it in facts. Her Majesty's recent illness did not commence till many months after the revaccination. There was no connection, direct or indirect, between the two.

I am, etc.,

October 31st, 1871.

WILLIAM JENNER, M.D.

P.S. I should not have contradicted so foundationless a statement had I not heard that, in consequence of the positive terms in which the assertion is made, it has received a certain amount of credence, and is so causing harm to the public health.

## THE INTRODUCTORY LECTURE AT THE MANCHESTER MEDICAL SCHOOL.

SIR,—I did not, until yesterday, read the strictures on my introductory lecture, contained in a paragraph in page 420 of the JOURNAL of October 7th, headed "Manchester Medical School." The anonymous contributor implies that the lecture consisted of "a series of carpings and warnings against such advances of modern science as the microscope and ophthalmoscope, and which vaunts the education of the past as contrasted with the present, is little adapted to the requirements of the present day." I must complain against the unfairness of these remarks. My observation was, "that I feared the attention of the students of the present day was too much devoted to minute or microscopic anatomy before having thoroughly acquired a knowledge of elementary anatomy"; that "I did not at all wish to discountenance minute anatomy; but during the course of medical study, it was much more material thoroughly to acquire the elementary knowledge before the student attempted microscopic examinations, *except under the direction of his teacher*." While appreciating in your work the value of such mechanical assistance as the microscope, stethoscope, and ophthalmoscope, you must not place too much reliance upon these aids, to the neglect of your own natural means of acquiring information in the science of anatomy in *post mortem* examinations, etc."

The correctness of my remarks is much confirmed by your statement of the number of students rejected at the preliminary examinations held during the period from July 1870 to May 1871 (BRITISH MEDICAL JOURNAL, p. 418). I believe most will coincide with my general remarks on theories, and I believe that I am not altogether singular in my opinion of those of Darwin and Huxley.

I now leave it to the readers of the BRITISH MEDICAL JOURNAL to decide between my statements and those of an anonymous contributor, whose remarks are founded at least upon misconception, if not upon wilful representation, and with whom I cannot be expected to enter into controversy.

Those who feel any further interest in the subject, will find a longer abstract of the introductory lecture in the *Medical Times and Gazette* of October 14th, page 487.

I am, etc.,

R. T. HUNT.

Manchester, October 28th, 1871.

\*.\* There is a full abstract of the lecture in the JOURNAL for Oct. 14th, page 448.

## MR. CHRISTOPHER HEATH ON CIRCULATION.

SIR,—I regret to find that you have belied the opinion I expressed to your publisher when he threatened to place our correspondence in your hands; viz., that you were "too intimately acquainted with the ethics of journalism to publish documents not intended for the public eye." As you have invited me "either to justify or retract my injurious imputations," I proceed to take the former course, with your permission.

Your quotation from my first letter respecting the circulation of the BRITISH MEDICAL JOURNAL and *Lancet* stops in the middle of a sentence, which in the original is completed as follows: "since the *Lancet* is distributed through the publishing trade, whilst the BRITISH MEDICAL JOURNAL circulates only among its own subscribers." This is a simple fact, which cannot be gainsaid. I applied the word "fallacious" to the Government stamp-returns because they are so, if employed to gauge the circulation of any paper the major part of whose issue is

unstamped. The "utterly surprising anticlimax," as you are pleased to call it, of my ignorance of the *Lancet's* precise circulation, would not have seemed so surprising to your readers had you finished the sentence as I wrote it: thus, "though I have every reason to believe that it (the circulation of the *Lancet*) exceeds that of all its London medical contemporaries put together." I am still of that opinion, and I think if you refer to the leading publishing firms, you will find my opinion confirmed.

To return to the circular. As I stated in my second letter, my complaint was not respecting the stamp-returns, but regarding the statement that the BRITISH MEDICAL JOURNAL "is now by far the most widely circulated of medical journals"—a statement which, up to that time, had not appeared in the JOURNAL itself. I observe that, within the last fortnight, a notice in almost the same terms has appeared in the title-page of the JOURNAL, which, therefore, now claims on its face the "largest circulation."

Your personal remarks upon myself I am content to leave unanswered, except where misstatements have been made. I nowhere stated that I wrote "in my new character of member of Committee of Council," my words being "I addressed you simply as a member of the Association, whose honour I hold to be involved in your proceedings." In my first letter, I had said, "As I happen to be a member of the Committee of Council of the Association, I shall take the earliest opportunity of bringing these fallacious statements under the notice of my colleagues, as I consider them dishonest and dishonourable to the Association of which I am a member." I am still of the same opinion, and have taken the earliest opportunity of bringing the subject before the Committee of Council. With respect to my seat on the Committee, which I am stated to have "somewhat anomalously accepted," I have only to remark that no one was more surprised than myself when my name was announced as a member of the Committee of Council at the Plymouth meeting; that I had no opportunity of either accepting or refusing the honour; and that I am not to be frightened out of doing my duty as a member of that Committee by personal abuse.

October 31st, 1871.

I am, etc.,

CHRISTOPHER HEATH.

## EPIZOOTIC APHTHÆ.

SIR,—I have seen recently in the daily papers, reports of several cases of epizootic aphtæ occurring in the human subject; and, as I am much interested in this matter, I should esteem it a favour if any of your numerous readers could supply me with full particulars of any cases that they have met with in their practice. For several months this disease in cattle, sheep, pigs, etc., has been traversing the length and breadth of our isles, thus giving medical men opportunities of studying one of the many diseases which are capable of being transmitted from the lower animals to man. It is to be regretted that medical teachers and practitioners (with some few exceptions) have been so apathetic in the study of comparative pathology. A study of this long-neglected department of science would furnish many facts which would help to place pathology upon a broader basis. It is a large field for research, and one that would amply repay any scientific observer.

I am, etc.,

JOHN A. MCBRIDE,

Lecturer on Veterinary Medicine and Surgery in the Royal Agricultural College, Cirencester.

## TREATMENT OF RETROFLEXION OF THE UTERUS.

SIR,—I have just perused with great interest the paper read by Dr. Beatty at the Association meeting at Plymouth on "The Radical Cure of Retroflexion of the Uterus." On thinking over the very ingenious plan devised or practised by him to obviate the difficulties and probable dangers attendant upon the mobility of the body of the uterus during the various movements of the patient, somehow there appeared before my "mind's eye" the simple and beautiful arrangement of the vertebral column in the ophidian reptiles. In this class of animals, the head and anterior half of the vertebral column can be raised and twisted about in all directions while the remaining portion is motionless.

This is effected by means of a ball-and-socket joint, the convex extremity of one vertebra fitting into the concave surface of the next. It has occurred to me that a hint might be taken from Nature, and a similar arrangement adopted in the instrument recommended by Dr. Beatty, by having a somewhat expanded concave surface on the vaginal end of the stem, applied so as to move smoothly over a pessary having the upper surface convex instead of flattened. My impression is, that the uterine stem would be enabled by this arrangement to move more smoothly and equably than on a flat surface. However, you can take the idea *quantum valeat*.

I am, etc.,

Bath, October 1871.

A. B. BRABAZON.

## OBITUARY.

RICHARD TONSON EVANSON, M.D.

WE have this week to record the removal from among us of a distinguished member of the medical profession and a most worthy colleague in our Association. Dr. Richard Tonson Evanson died on October 26th, at his residence, Torquay, in his seventy-second year. He had been suffering for some years from irritability of the bowels and chronic diarrhoea, and from fatty degeneration of the heart, which was the immediate cause of his death. Notwithstanding these ailments, his spirits never flagged; and he maintained his interest in everything that concerned his profession, whether scientific or social, as warm and lively as the youngest and strongest among us. On the night previous to his death, he was restless, and had determined to remain in bed somewhat longer than usual; but about midday he was found to have passed away tranquilly, without a struggle, and as if in sleep.

Dr. Evanson was a native of the county of Clare in Ireland, and received his education in Trinity College, Dublin, of which he was a distinguished *alumnus*. He commenced his medical studies as an apprentice to the late Sir Philip Crampton, then Surgeon-General to the Army in Ireland; and in due time became a Fellow of the Royal College of Surgeons. He soon, however, turned his attention to medical practice; and, having graduated as Doctor in Medicine in the University of Glasgow, he settled in Dublin as a physician, and undertook the office of Lecturer on *Materia Medica* in the Park Street Medical School. There he was associated with the late Sir Henry Marsh, Dr. Arthur Jacob, Dr. Beatty, Dr. W. Stokes, and other teachers whose names brought an European reputation to the Medical School of Dublin during the second quarter of the present century. From Park Street School, Dr. Evanson was subsequently transferred to the Chair of Medicine in the Royal College of Surgeons; and he was rapidly rising into eminence as a practitioner when the affection of the mucous membranes, under which he suffered to the last, obliged him to seek health in warmer climates. For many years he was a wanderer upon the continent of Europe; but during all that time he never abandoned the practice of his profession, and many English persons of distinction enjoyed the benefit of his skill and were his patients in the cities where he sojourned. The last of these was the late Duke of Northumberland, whose medical adviser and confidential friend he was for some years. After the Duke's death, he retired from private practice; but, as we have said, his love for his profession never diminished, and he continued in close and friendly intimacy with a large circle of its members, by whom his kindness of heart, comprehensive charity, and never-failing benevolence, were warmly estimated.

Dr. Evanson's literary abilities were very considerable. He was a frequent contributor to the current medical literature of his time. In 1836 he published, in conjunction with his early and never forgotten friend Dr. Maunsell, a *Practical Treatise upon the Management and Diseases of Children*, which was at once recognised as a standard work, was reprinted in America, translated into German, and rapidly passed through five editions. He did not, however, confine his labours within professional limits. As he said in a very recent letter to an old companion, he had early formed a habit of rhyming, and never abandoned it up to the close of his life. So lately as 1868, he published a poem under the title of *Nature and Art*, with a number of "occasional verses and elegiac stanzas", the latter of which teem with the tenderness and affection which characterised his gentle nature. The motto which he selected for the title-page of this book was indeed the key of his whole life:

"He prayeth best who loveth best  
All things, both great and small;  
For the dear God who loveth us,  
He made and loveth all."

Many of our associates had the good fortune to share in the last public act of Dr. Evanson's life, when he presided at the splendid entertainment given by the medical men of Torquay to the members of the British Medical Association who attended the annual meeting at Plymouth in August last. On that memorable occasion, Dr. Evanson was unanimously chosen by his brethren at Torquay as the most fitting person to take the chair; and all who had the happiness of being present can bear testimony to the highly efficient manner in which he discharged the duties of his office. Although evidently suffering and weakened by the disease that was preying upon him, it seemed as if his former vigour and eloquence, for which he was always remarkable, had returned for the occasion, and he spoke with the energy of youth and the elegant diction of a Christian philosopher and poet. His bright, genial, social, warm-hearted character, never showed more clearly than

it did then, placed as he was at the head of a brilliant assembly of the *élite* of the profession, among whom were his ardent admirers, and one at least of his oldest and most loving friends. We have reason to know that the success of that day was most gratifying to that amiable and good man; and it would seem as if Providence had afforded him that opportunity of taking leave of a profession in which he had so long laboured and which he so well loved.

LANGSTON PARKER, F.R.C.S., BIRMINGHAM.

It is with much regret that we announce the death of this eminent practitioner, which took place from bronchitis, on Friday, the 27th ult., in the 67th year of his age, at his residence, Paradise Street, Birmingham. Mr. Parker was born in that town in 1803, and there commenced his professional education; he thence proceeded to London (St. Bartholomew's), concluding his curriculum by a visit to the hospitals of Paris. His membership of the Royal College of Surgeons dates from 1828, and two years later he commenced practice in his native town, as successor to his father. The active character of his mind soon led him to engage with ardour in various schemes to promote the scientific and professional education of Birmingham. He was associated with Mr. W. Sands Cox in the establishment of Queen's College, in which, for a quarter of a century, he occupied the chair of Anatomy. His services to Queen's Hospital date from the foundation of that important charity, of which, for a like period, he discharged the duties of Honorary Surgeon. On his retirement from that office he became Consulting Surgeon, which appointment he held to his death. He was also Consulting Surgeon to the Leamington Hospital for Diseases of the Skin. Of the Birmingham Philosophical Institution he was likewise an active promoter, and delivered to its members a remarkable course of lectures "On the Effects of Certain Mental and Bodily States upon the Imagination." These were subsequently reprinted in the *Analyst*, a quarterly journal conducted by W. Holl, F.G.S., and Neville Wood, and are contained in five consecutive numbers, the last appearing in the issue for January 1837. They were greatly admired for their elegance of composition and felicity of illustration; and it is much to be regretted that their author never published them in a substantive form. The contributions of Mr. Parker to medical literature were numerous and important. Of these, one of the earliest was a volume of 300 pages, *The Stomach in its Morbid States, being a Critical Inquiry into the Nature and Treatment of Diseases of that Organ*, 8vo, 1837. This, although called for, never went into a second edition, the author preferring to condense the subject in a smaller work, *Digestion and its Disorders, in reference to Dietetics and Diseases of the Stomach*, 8vo, 1849. We may also mention his paper on *The Nature and Treatment of some Painful Affections of Bone*, published in 1852; his *Course of Lectures on Clinical Surgery*, 1855 (ASSOCIATION MEDICAL JOURNAL); and his elegant monograph on *The Modern Treatment of Cancerous Diseases by Caustics or Enucleation; An Inquiry into the Effects of many new Remedies in Arresting the Progress of Cancer*, being the substance of the Annual Address on Surgery, read by Mr. Parker at the twenty-fourth annual meeting of the British Medical Association in 1856.

But, as it was in the successful treatment of a special class of disorders that the deceased gentleman obtained a more than European reputation, so it is as a Syphilographer that he must rest his claim to be remembered by posterity. His *Clinical Lectures on Infantile Syphilis*, published in 1858; his monograph on *Primary and Secondary Syphilis of the Uterus*, 1859; his papers on *Latent Syphilis*, published in 1863; and *On Some Diseases and Accidents to the Sexual Organs not of a Syphilitic Nature*, which appeared in the *BRITISH MEDICAL JOURNAL* in 1868; his essay on *The Mercurial Vapour Bath*, of which a second and rewritten edition appeared in 1868, and in which he advocates "moist" in preference to "dry" fumigation—all indicate the possession of a large and varied knowledge; while his classical work, *The Modern Treatment of Syphilitic Diseases*, of which he lived to see a fifth edition, embodying the results of thirty years' experience, "entirely rearranged and rewritten" shortly before his death, is a truly practical and comprehensive treatise.

It was not only in the literature of his own country and profession that Mr. Parker was versed: it was difficult to mention a continental work on medicine or surgery which was unknown to him. He was deeply read in fiction, and took to the last an absorbing interest in the drama, of which his knowledge was profound and critical. In private life few men were more respected; his kindly disposition, genial temperament, and honourable character, endearing him to a large circle of friends, by whom his loss will be long felt. He died "in harness", having been consulted by patients on the evening preceding his death. He was interred on Wednesday last, in the family vault at Aston, whither he was followed by a large concourse of friends, anxious to pay

the last tribute of respect to his memory. He leaves one son, Mr. Adams Parker, a Licentiate in Dental Surgery of the Royal College of Surgeons, engaged in the successful practice of his profession, and holding office in the hospital which his father served so long and so well.

#### ARTHUR KEMPE, F.R.C.S., EXETER.

IT is our painful duty to record the decease of Mr. Arthur Kempe, which took place suddenly, at his residence, Southernhay House, Exeter, on Wednesday, October 25th. Mr. Kempe was the youngest son of the late Rev. John Kempe, for many years the rector of Fowey, Cornwall, at which place Mr. Kempe was born in the year 1813. He received his education at Blundell's School, Tiverton. His professional studies were commenced at the Devon and Exeter Hospital in the year 1832, under the late Mr. Samuel Barnes, one of the most distinguished surgeons of his time, to whom he was apprenticed. He studied subsequently at St. Bartholomew's Hospital, London, where he took a prize for surgery; and eventually settled in Exeter in 1839. Mr. Kempe was thoroughly a man of business, always industrious, and very painstaking; of gentlemanly bearing, and possessing much warmth of feeling and sympathy towards his patients. He soon became a favourite, and his hands became full of work. He was elected early in life one of the Surgeons of the Exeter Incorporation, also of the Exeter Dispensary, and the Lying-in Charity, which offices he held for many years, and eventually relinquished the two former appointments on his election as Surgeon to the Devon and Exeter Hospital in 1854. From this time, he rapidly rose to occupy one of the highest positions as a consulting surgeon; his judgment was good, and he performed his operations with boldness, dexterity, and celerity. Thus, his fame speedily became known through the country, and for many years his opinion was sought and valued by many of the leading families in the county of Devon.

Mr. Kempe was never married. All his energies were thrown into his professional work; and so great was his zeal, that for more than twenty-five years he never took a holiday or rest from the daily routine of his labours. This constant and unwearied attention to his profession, as might be expected, after a time began to tell on Mr. Kempe's health; and for the last four years he complained at times of indigestion, palpitation of the heart, etc. At Christmas last, he became painfully aware that he could not continue his work as heretofore; he therefore determined only to see patients in consultation. This, however, in April, he was compelled to relinquish; and by the counsel of his professional advisers, he went to Italy, subsequently seeking change and retirement in that quiet and health-giving place Chagford. On his return, he seemed in some respects improved. He was able to take his drive daily, and see some of his intimate friends. He resigned his appointment as Surgeon to the Devon and Exeter Hospital in June, and was elected Consulting Surgeon.

Up to a few days previous to his decease, his health had been much as usual; but on Sunday morning, October 22nd, a sudden prostration came on, and Dr. Drake, his physician, found him cold and pulseless, in which condition he remained for some time; he rallied, however, and was about on Monday and Tuesday as usual. On Wednesday morning, on his servant's entering the room, she came in only to hear him draw his last breath.

Mr. Kempe was distinguished during a long life of usefulness by an undeviating regard and consideration for the poor. He was unanimously elected one of the guardians of the poor, which office he filled for some years, and was, on his retirement from public life, the governor of that body, his opinions carrying always great weight in the discussions. He leaves behind him a beautiful memorial of his good works in a chapel attached to the Devon and Exeter Hospital, which he erected at a cost of £1,800. Mr. Kempe made an offer, about two years since, to the Committee of the same institution, to erect and present to them a sanatorium to accommodate thirty patients who were convalescent, having seen himself how valuable such an addition would be to the parent institution; but his offer was refused by the Managing Committee, on the plea of their doubt of the funds to support it being forthcoming. Only a few days before his death, he wrote to the Town Council, offering to erect, in any suitable place, a drinking fountain, which should also carry a lighted clock. This matter was under consideration at the time of his decease.

His remains were interred in a vault in the yard of St. Sidwell's Church, a very large number of his friends attending the funeral as a last tribute of respect to one who had been so highly valued during his life. It falls to the lot of few men to enjoy so fully the confidence of so large a sphere of persons as did Mr. Kempe; his loss is therefore lamented by many. Those who enjoyed the privilege of intimacy with him, feel that they have lost a friend whose place is not easily filled.

#### JAMES FAWCUS, M.D. LOND.

DR. JAMES FAWCUS, Inspector-General of Jails in Lower Bengal, was born in 1833, and died at his mother's house in North Shields, on October 11th, 1871, of pneumonia, supervening on fever caught at Calcutta. In early life he spent some years in the Vale of Keswick, and became well acquainted with the geology, mineralogy, and natural history of the Lake country. He studied at University College, London, and afterwards in Paris and Vienna, visiting also various other seats of medical learning. By his love for his profession, the sweetness of his temper and utter unselfishness of his nature, he won the love and esteem of his teachers and fellow students.

In the spring of 1856 he was appointed assistant-physician to the hospital at Renkioi on the Dardanelles, which was established under the superintendence of Dr. Parkes, in the rear of the hospitals in the Crimea and at Scutari. He also volunteered for the Crimea, and was for some time attached to the hospital of the Light Division at the front.

For his services there he received the thanks of the officers, and afterwards Sir William Codrington procured him the Crimean medal. It was characteristic of him, that he left immediately after the duties were over, that he might not in any way share the merit of his military medical friends. After returning to Renkioi, where he served till the end of the war, he was also appointed assistant-surgeon to the Land Transport Corps, which had at that time over six thousand mules at the Dardanelles and a large number of men. Here, at Abydos, he remained some time. "He discharged," says Dr. Parkes, "both sets of duties with great zeal and very ably. He was at that time only 22 years old, full of vigour, very strikingly handsome, and with a sweet, never-ruffled temper which made him a favourite with all. His service in the East was very pleasant to him, and he enjoyed greatly the active, energetic life he led there."

After studying and travelling on the Continent for about two years, he passed the competitive examination for the Indian Medical Service, in which he took a very good place; and in February 1859 he went to Bengal. He was, on April 22nd, 1859, ordered to China with the 47th Native Infantry, and after being at Canton for a short time was appointed to the charge of Stanley Hospital near Hong-Kong. After a visit of some months to New Zealand he returned to India, and then, by the introduction of Dr. Parkes, first made the acquaintance of Dr. Frederick Mouat, the Inspector-General of Jails in Lower Bengal. Dr. Mouat saw at once what a valuable man he was, and procured for him the civil-surgeoncy of Monghyr. When the Inspector-General went to visit the jail at Monghyr, he saw, to use Dr. Mouat's words, "how valuable Dr. Fawcus's work had been—how important had been his influence in introducing, and very rapidly giving effect to, changes that had the reclamation of the prisoners for their object". By the Inspector-General's recommendation he was soon appointed superintendent of the jail at Alipore, a large jail containing about 2500 prisoners, in a suburb of Calcutta; and at the same time Dr. Fawcus held the assistant-surgeonship of the General Hospital. Dr. Mouat tells stories of his slipping away from a roomful of friends to sit up with a patient, about whom he was anxious, sleeping in the hospital or the jail. In the duties of superintendent he was "wonderfully devoted and got the love of every colleague, subordinate, and prisoner. His interest was in everything that tended to make the prisoners better men".

In 1865 Dr. Fawcus was appointed Deputy Inspector-General of Jails, and since then has frequently had Dr. Mouat's duties when he was away. Throughout Dr. Mouat's able Reports of the immense prison system of Lower Bengal, Dr. Fawcus's name and work is frequently spoken of in the highest terms of praise, and at the close of the Report of 1867 "the Lieutenant-Governor desires to thank Dr. Fawcus for his energetic and intelligent administration of the department during the absence of Dr. Mouat in England".

Dr. Fawcus was for two or three years engaged with Dr. Cunningham in scientific researches into the pathology of cholera; and the Inspector-General, in his Report for 1869, says: "The only really satisfactory information which I have received was from Alipore Jail. There is no reason why medical officers who have not a tithe of the duties and responsibilities of Dr. Fawcus should not investigate the diseases which occur in their jails with the care and minute attention which he devotes to the work." Of Dr. Fawcus's Reports, which show the result of long labour and great numbers of *post mortem* examinations made under circumstances more favourable for arriving at just conclusions (respecting embolism, for example) than any which could have occurred in this country, Dr. Mouat says: "It would be difficult to overrate their interest and importance in the new and right direction which the general inquiry into cholera has now taken." What efforts such labours as these would cost in the exhausting climate of Calcutta, every medical man must know.

On Dr. Monat's retirement in 1870 Dr. Fawcus was appointed Inspector-General, and shortly afterwards went away on a visit to his jails through Orissa and Assam. But his health was now broken. The immense wear and tear of his office, and the unhealthy places which he had to visit and remain in at length told even on his strong frame. He had, with a view of improving the health of Alipore, undertaken some works of drainage in the malarious soil there; and when he began to suffer, as it was ever his way to care nothing about himself, he still went on with his work. Moreover, so much difficulty was anticipated in filling his office that he was pressed by his official superiors to stay longer than was at all right for his health. Again, he thought too little of himself, and did so. He left India in April of this year; and, after spending the summer partly in England, partly in France, he at length, when very weak, caught pneumonia at Melrose and returned to his mother's house to die, preserving his life-long sweetness, patience, and care for the good of others to the last.

Dr. Fawcus has left a widow and young family; who, with very many friends, will long lament his loss.

#### WILLIAM DANIEL MOORE, M.D., DUBLIN.

WE regret to announce the death of Dr. W. D. Moore, which took place on October 28th. The cause of his death was progressive muscular atrophy, with which he had been afflicted since the beginning of 1867. We hope to give a biography of Dr. Moore in our next number.

## THE POOR-LAW MEDICAL SERVICE OF GREAT BRITAIN.

### THE USE OF STIMULANTS IN WORKHOUSE INFIRMARIES.

THE Special Committee of the West Derby Board of Guardians last Wednesday presented their report on the use of stimulants in workhouses. As the result of their inquiries, they point out that their union occupies a very unfavourable position in comparison with other parishes and unions, and recommend a "non-alcoholic treatment" wherever it can be adopted, advising that the medical officers should be required to administer alcoholic liquors with as much care as medicines of a poisonous nature. They give the following return from twenty-two unions and parishes of the consumption of stimulants in their respective workhouses, showing the total population, the yearly cost of stimulants per head, and the death-rate on an average of two years:—

PARISHES AND UNIONS.	Total Population.	Total Deaths.	Cost of Stimulants.	Cost per Head.	Deaths One in
			£ s. d.	s. d.	
West Derby .....	4538	400	1257 6 0	5 6	11

A SUPERANNUATION of £80 a year was last week granted by the West Derby Guardians to Dr. Reid, who has been medical officer of the Bootle district for thirty-two years.

#### POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

A SPECIAL meeting of the Council and Members of the Poor-law Medical Officers' Association will be held at the Medical Club, on Tuesday, November 7th, 1871, at 7 P.M. precisely, when Mr. Corrance, M.P. for East Suffolk, will submit for consideration the Bill which he intends to bring forward next session, "For the better regulation of medical poor relief, and for establishing dispensaries in England and Wales", and on which occasion the sense of the meeting will be taken as to the advisability of incorporating therewith certain sanitary clauses, which have been referred by the Social Science Association to the Joint Committee of that and the British Medical Association. The questions which will be raised do not affect the Poor-law medical officers only, but will be found interesting to medical officers of health and to all social and sanitary reformers.

## MEDICAL NEWS.

### PROVINCIAL MEDICAL SCHOOLS.

THE annual return of the number of gentlemen pursuing their anatomical studies at the eight recognised provincial medical schools has just been made to Dr. Ogle, the recently appointed Government Inspector of these institutions, from which it appears that there are this session 368 medical students, being an increase of eleven over the number of last year, although only two schools show an increase; viz., those of Manchester and Bristol.

	1871.	1870.
Manchester Royal School of Medicine and Surgery .....	111	98
Birmingham Royal School of Medicine and Surgery .....	60	76
Liverpool Infirmary and School of Medicine and Anatomy .....	54	58
Leeds School of Medicine .....	45	46
Bristol Old Park Medical School .....	36	30
Cambridge University School .....	27	—
Newcastle-upon-Tyne College of Medicine .....	25	35
Sheffield Medical Institution .....	10	14

Total 368 357

Since the last report of the number of metropolitan students pursuing their studies this session, a few more have been allowed to register, making a total of 1,491 against 1,317 last year, or an increase of 174, the number of new entries or freshmen being 472.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At the ordinary quarterly meeting of the College, on Thursday, October 26th, the following gentlemen, having passed the required examinations, were admitted members.

Cook, John, M.D. Edin., Upper Wimpole Street  
Glynn, Thomas R., M.B. Lond., Rodney Street, Liverpool  
Payne, Edwin, M.D. St. And., Walton House, Selhurst Road, South Norwood  
Squire, William, Orchard Street, Portman Square

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, October 26th, 1871.

Burgess, Edward Arthur, Bethnal Green Road  
Cane, Leonard, Queen Square, W.C.  
Gatsell, Thomas, East Street, Walworth  
Harris, Thomas Davies, Llanest, Fishguard  
March, Frederick Kimbell, Braumston, near Rugby  
Meredith, William Henry, Netherton, Worcestershire  
Rees, Albert Barnes, Swansea  
Watson, John Willocks, Heigham Hall, Norfolk

The following gentleman also on the same day passed his first professional examination.

Goddard, Charles Cane, Guy's Hospital

#### MEDICAL VACANCIES.

THE following vacancies are announced:—

ALNWICK INFIRMARY—Surgeon.  
ASHTON-UNDER-LYNE UNION—Medical Officer for District No. 10.

AXMINSTER UNION, Devon—Medical Officers for the Colyton and Shute Districts.  
 BRAMLEY UNION, Yorkshire—Medical Officer for the New Wortley District.  
 CARDIGANY UNION—Medical Officer for District No. 3.  
 COUNTY OF WICKLOW INFIRMARY—Apothecary: £27:13:10 per annum.  
 CUMBERLAND INFIRMARY, Carlisle—Assistant to the House-Surgeon.  
 DEAF AND DUMB INSTITUTE, Brighton—Surgeon.  
 DERBY PROVIDENT DISPENSARY—Two Medical Officers.  
 DERBYSHIRE LUNATIC ASYLUM, Mickleover—Resident Medical Superintendent.  
 EAST PRESTON UNION, Sussex—Public Vaccinator for District No. 3.  
 EXETER LYING-IN CHARITY—Surgeon.  
 HAMPSTEAD SMALL-POX HOSPITAL—Assistant Medical Officer and Dispenser.  
 HONITON UNION, Devon—Medical Officer for District No. 8.  
 HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton—Resident Clinical Assistant.  
 HOSPITAL FOR WOMEN, Soho Square—Assistant Physician; Clinical Assistant.  
 KILRUSH UNION, co. Clare—Medical Officer for the Kilkee Dispensary District: £100 per annum.  
 LEEDS GENERAL INFIRMARY—Assistant Resident Medical Officer.  
 LINCOLNSHIRE—Medical Officer for the County Gaol for the parts of Lindsey: £120 per annum.  
 LIVERPOOL INFIRMARY FOR CHILDREN—House-Surgeon: £80 per ann.  
 LONDON FEVER HOSPITAL—Physician.  
 LOUDOUN, Ayrshire—Medical Officers for the Newmilns and Darvel Districts: £30 per annum each.  
 METROPOLITAN DISPENSARY, Fore Street—Surgeon.  
 MIDDLESEX HOSPITAL MEDICAL COLLEGE—Lecturer on Materia Medica.  
 NORTH DEVON INFIRMARY, Barnstaple—House-Surgeon: £100 per annum, board, lodging, etc.  
 NORTH UIST, Inverness-shire—Parochial Medical Officer: at least £200 per ann.  
 OLD KILPATRICK, Dumbartonshire—Medical Officer for the Western District: £25 per annum; and Sanitary Medical Officer: £5 per annum.  
 PADDINGTON, Parish of—Medical Officer and Public Vaccinator for the Eastern District: £120 per annum, and Vaccination and extra fees.  
 PEWSEY UNION, Wilts—Medical Officer for the Pewsey District and the Workhouse.  
 POPLAR HOSPITAL, East India Road—Resident Medical Officer: £80 per annum, rising £10 per annum.  
 ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road—Surgeon.  
 ROYAL SURREY COUNTY HOSPITAL, Guildford—House-Surgeon: £75 per annum, board, residence, and washing.  
 SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY—Assistant House-Surgeon: £65 per annum, apartments, washing, and board.  
 SMETHWICK, Staffordshire—Medical Officer of Health: £25 per annum.  
 SUSSEX COUNTY HOSPITAL, Brighton—Surgeon; Assistant-Surgeon.  
 TEIGNMOUTH, DAWLISH, and NEWTON DISPENSARY and INFIRMARY—House-Surgeon: £50 per annum, and board and lodging.

### MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.*

CAMPELL, W. Macfie, M.B., appointed Senior House-Surgeon to the Liverpool Northern Hospital, *vice* T. D. Chalmers, M.B., resigned.  
 CARTER, Sidney Herbert, M.B., appointed Assistant Medical Superintendent to the Bristol Lunatic Asylum, *vice* J. W. Day, Esq., deceased.  
 JACKSON, Charles, L.K.Q.C.P.Irel., appointed Medical Officer, etc., for the Ballyhaize Dispensary District of the Cavan Union, *vice* Wm. Atkin, L.K.Q.C.P.Irel., resigned.  
 MACMASTER, Andrew, L.R.C.P.Edin., appointed Medical Officer, etc., for the Eastern Division of the Omagh Dispensary District of the Omagh Union, co. Tyrone, *vice* Arthur C. Walker, L.F.P.S.Glasg., resigned.  
 MARRIOTT, C. W., Esq., appointed Surgeon to the Warneford, Leamington, and South Warwickshire Hospital, *vice* J. E. Male, Esq., deceased.  
 O'BRIEN, Daniel, elected Medical Officer for the Ennis Union Workhouse.  
 RUTHERFORD, David J., M.D.Edin., appointed Parochial Medical Officer for Unst, Shetland, *vice* Henry L. Saxby, M.D., resigned.  
 THORPE, G. E. K., Esq., appointed House-Surgeon to the Public Hospital and Dispensary, Sheffield, *vice* Algernon Taylor, Esq., resigned.  
 VASEY, C. Lyon, Esq., appointed Junior House-Surgeon to the Liverpool Northern Hospital, *vice* W. Macfie Campbell, Esq., promoted.

### BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.*

#### DEATHS.

BOWEN, David, Esq., Surgeon, at Newport, Pembrokeshire, on October 22nd.  
 \*EVANSON, R. T., M.D., at Torquay, on October 26th.  
 KEMPE, Arthur, Esq., at Exeter, on October 28th.  
 MOORE, William, M.D., at Dublin, on October 28th.  
 \*PARKER, Langston, Esq., Surgeon, at Birmingham, on October 27th.  
 REED, Thomas, Esq., Surgeon, at Slieveroe, co. Monaghan, aged 63, on Oct. 16th.

DR. MORELL MACKENZIE has been elected Corresponding Member of the Royal Buda-Pesth Society of Physicians. Dr. Prosser James has been elected Corresponding Member of the Academy of Medicine of Lyons. Dr. James has spent a large part of his time in the South of France.

THE GRESHAM LECTURES for the Michaelmas term will be delivered by Dr. Symes Thompson, on November 10th, 11th, and 13th. The subjects will be: the Digestive Organs in Health; the Disorders of Digestion; and Cholera. The lectures will commence each evening at seven o'clock.

### OPERATION DAYS AT THE HOSPITALS.

MONDAY ..... Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
 TUESDAY ..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
 WEDNESDAY... St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
 THURSDAY ... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.  
 FRIDAY ..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.  
 SATURDAY... St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

### MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—Medical Society of London, 8 P.M. Dr. Lichtenberg, "Rhinoplastic Operation—Two Cases, with patients"; Mr. Thomas Bond, "Urethral Rheumatism."  
 TUESDAY.—Pathological Society of London, 8 P.M. The following specimens will be exhibited:—Dr. Moxon, Circumscribed Pleurisy and Pneumonia in a Syphilitic Man; Dr. Moxon, Destruction of Trachea by Syphilis; Dr. Pye Smith, Cystic Disease of the Kidney; Dr. Dickinson, Intracranial Aneurism productive of Sudden Death.  
 WEDNESDAY.—Hunterian Society, 7.30 P.M.: Council Meeting. 8 P.M.: Mr. Bryant, "On Insuperable Constipation and its Treatment."  
 FRIDAY.—Clinical Society of London, 8.30 P.M. Dr. John Murray, "On a Case of Paracentesis Thoracis"; Dr. Anstie, "The continuation of a Case previously reported"; Mr. Christopher Heath, "A Case of Wound of the Intestine during Ovariectomy, with Recovery"; Dr. Ogle, "Notes on the Temperature in Tetanus."

### EXPECTED OPERATIONS AT THE HOSPITALS.

WEST LONDON HOSPITAL, Thursday, November 9th, 3 P.M. External Urethrotomy, by Mr. Teevan.

### NOTICES TO CORRESPONDENTS.

ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

TO PURCHASERS.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with halfpenny stamps for the amount.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

ERRATA.—In Dr. Hitchman's paper on Paralysis of the Insane, at page 495, column 1, line 14, for "impossible", read "possible"; and on column 2, line 22, for "ears", read "arms". The proof was forwarded to Dr. Hitchman; but the envelope containing it was by accident wrongly addressed. We regret that he was thereby deprived of the opportunity of revising his valuable paper.

#### CONSULTATION FEES.

SIR,—I should feel grateful if some members of our Association would inform me what is the usual fee charged by the ordinary medical attendant when he meets another practitioner in consultation. The Shropshire Branch of our Association, in their tariff of medical fees, say "not less than double the usual fee"; but, surely, is not this very inadequate recompense for a consultation extending over an hour and a half? Some practitioners, I know, charge the consultant's usual fee of a guinea. Is this usual? I am, etc., CANTAB.  
 October 24th, 1871.

DR. A. A.—Duly received.

SIR.—Where can I obtain, and what is the price of, the Thimble mentioned by Mr. Lawson Tait at the general meeting of the Birmingham and Midland Counties Branch? I am, etc., JOHN SLEMAN.  
 Gunnislake, Tavistock, October 30th, 1871.

As an L.R.C.P.London, will it be proper for me to put on my door-plate Dr. —? If not, would Mr. —, Physician, be right?

\*. Mr. —, Physician, is, in such a case, technically right.

**NOTICE TO ADVERTISERS.**—Advertisements should be forwarded direct to the Printing-Office, 37, Great Queen Street, W.C., addressed to Mr. F. H. HEATHCOTE, not later than *Thursday*, twelve o'clock.

**ERRATUM.**—In Dr. W. V. Lush's article on "The Duration of Vaccine Prophylaxis," published last week in the *BRITISH MEDICAL JOURNAL*, the age of the child (Case 11) should be four years and nine months, not five years and nine months, as there stated.

#### CHLORAL IN PREGNANCY.

**SIR.**—In reply to a letter in your last edition, from "An Associate," on the action of chloral on the fetus *in utero*, I think he errs in supposing that the death of the fetus was caused by the chloral. He does not really state this; but I conclude it is his opinion from the tone of his letter. I find in my case-book that within this month I have given large doses of chloral to three parturient females, who have been happily delivered of living children. I constantly use chloral in such cases, without any apparent result to the children. Dr. Du Hamel, in the *American Journal of Medical Science*, October 1870, brings forward several cases of its use in child-bearing, and I am not able to find any opposing records. Leamington, Oct. 1871. I am, etc., JAMES THOMPSON, M.D.

#### THE DYTE APPEAL FUND.

**SIR.**—In addition to the £42 already announced as received for the Dyte v. St. Pancras Guardians Appeal Fund, I have to acknowledge, with best thanks, the following subscriptions. In doing so, however, allow me to add that, unless further aid be speedily forthcoming, Dr. Dyte will probably lose some hundreds in the prosecution of his just claims, admitted as such by the Guardians themselves.

Andrew, Dr. James	-	-	£t	1	0

#### REGISTRATION OF DEATH.

**DR. FELCE** presents his compliments to the Editor, and begs to enclose for insertion in the *BRITISH MEDICAL JOURNAL* a letter on a most important matter which he has addressed to the Registrar-General, together with a copy of the reply thereto.

"Sir,—I beg most respectfully to call your attention to a grave defect which exists, at all events in this district, in the system of registering deaths; certain deaths being registered as 'certified,' whereas the persons who 'certify' are not legally qualified medical practitioners. The persons alluded to (three in number) profess to have received degrees from an American University recently, and, indeed, may have done so; but they have certainly not left this country for the purpose, neither do they possess any degree or diploma entitling them to have their names placed upon the *Medical Register*. I am told by the Registrar for the subdistrict of St. Mary, Paddington, that he has 'no instructions to distinguish between men legally qualified and otherwise'; that he depends on his 'local knowledge of men in receiving their certificates'; and that lately, upon a neighbouring druggist coming and telling him he had taken his degree, and was now qualified to practise, he immediately complied with his request, and supplied him with a book of forms of certificates of cause of death; and that he has since received certificates from him, and registered the same. (This is one of the men I refer to, and he possesses no legal qualification.)

"Upon my asking the Registrar if he never consulted the *Medical Register* to ascertain if a person certifying was a registered medical practitioner, I was astonished to find that he did not possess a copy of the book; and that although he had held the office for nearly six years, he had never been supplied with, or instructed to obtain a copy of, the work in question. The practice of registering deaths as certified upon the certificates of such persons as those I have indicated is surely fraught with great danger to the public, and is not likely to increase the accuracy of the *Register*; circumstances which will, I trust, lead to the adoption of some remedy for the evil of which I complain, the more especially as the members of the medical profession have at all times given their willing and gratuitous aid to the perfecting of this part of the work of the department over which you preside.

I have the honour to be, sir, your most obedient servant,

"STAMFORD FRICK, M.R.C.P.E., etc.

"12, Chippenham Road, W., October 26th, 1871."

"General Register Office, Somerset House, October 30th, 1871.

"Sir,—I have to thank you for calling my attention to the fact that Mr. Aveling ascribes causes of death written by unqualified practitioners, treating them as genuine, and writing under them on the register books 'certified.' I have this day written to him on the subject. Her Majesty's Government have gratuitously disseminated amongst medical practitioners and registrars the latest nomenclature of diseases in several languages; but they do not authorise the expense of annually providing registrars with the *Medical Register*; consequently they have a difficulty in informing practitioners falsely claiming to be qualified, that what they say is untrue.

"Causes of death written by some unqualified practitioners may be held to be more accurate than some of the strange statements as to the fatal disease made by informants who legally qualified medical practitioners have not been in attendance. I have the honour to be, sir, your faithful servant,

"GEORGE GRAHAM, Registrar-General.

"S. Felce, Esq., 12, Chippenham Road."

#### MEDICAL ETIQUETTE.

**SIR.**—As my attention has only been this day drawn to Mr. C. Royston's letter, regarding my alleged want of professional etiquette towards him, in your last week's impression, I must beg that your readers will suspend their verdict until they hear both sides. In great haste, I am, etc.,

Nov. 2, 1871.

DELAMARK FREEMAN.

#### PUNCTURE OF THE INTESTINE IN TYMPANITES.

**SIR.**—If Mr. J. Hancock Wathen will take the trouble to turn up the literature of the subject, he will find that puncture of the intestine for the relief of flatulence, even amongst human patients, is no novelty. I have known of it for many years; and I find in my note-book an elaborate history of a case where I made several punctures into the intestines each day for six consecutive days, always with great relief, and the dates are from the 18th to the 24th of March, 1868. This case I published soon afterwards, but cannot at present find a reference to it. Thus, if there is any credit in priority at all, it belongs to me rather than either to Dr. Davey or my friend Mr. Teale. I am, etc.,

7, Waterloo Street, Birmingham, November 1871.

LAWSON TAIT.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The *Liverpool Albion*, Oct. 30th; The *Eastern Morning News* and *Hull Advertiser*, Oct. 28th; The *Newcastle Daily Chronicle*, Oct. 28th; The *American Register*, Paris, Oct. 21st; The *Dudley Herald* and *Wednesbury Borough News*, Oct. 28th; The *Newcastle Daily Journal*, Oct. 28th; The *Bristol Daily Post*, Oct. 24th; The *Argyllshire Herald*, Oct. 28th; etc.

#### COMMUNICATIONS, LETTERS, ETC., have been received from:—

Sir William Jenner, Balmoral; Dr. Priestley, London; Mr. Husband, York; Dr. T. E. Beatty, Dublin; Dr. Smart, Penge; Dr. Dalby, London; Dr. Patrick Jamieson, Peterhead; Dr. A. Wahlteuch, Manchester; Dr. Hitchman, Mickleover; Mr. J. S. Ferris, Uxbridge; Miss Thomas, Newport, Pembrokeshire; Mr. T. H. Bartleet, Birmingham; Dr. Sheen, Cardiff; Dr. Shapter, Exeter; Dr. R. Hibbert Taylor, Liverpool; Dr. G. Buchanan, Glasgow; Dr. Shettle, Reading; The Secretary of the Royal Medical and Chirurgical Society; Mr. A. B. George, Whitechurch; Mr. J. E. Wood, Rochdale; Dr. Elliot, Carlisle; Mr. J. E. Cornish, Manchester; Mr. R. Scarlett, Thornbury; Messrs. Cowan and Sons, Barnes; A Member; Mr. T. Taylor, Birmingham; Dr. Julius Althaus, London; Dr. Alfred Meadows, London; Dr. Jukes Styrap, Shrewsbury; M.D.; The Secretary of the Clinical Society; Dr. George Johnson, London; The Secretary of the Hunterian Society; Mr. Christopher Heath, London; Mr. C. H. Roper, Exeter; An Associate, Exeter; Mr. B. Wilson, Manchester; Dr. Wolfe, Glasgow; Mr. Carter, Richmond, Yorkshire; Dr. Trollope, St. Leonard's-on-Sea; Mr. J. Sleman, Gunislake; Mr. C. W. ## CLINICAL LECTURE

ON A

## CASE OF EXTREME CIRRHOSIS OF THE LIVER IN EARLY LIFE.

By W. B. CHEADLE, M.D., F.R.C.P.,

Senior Assistant-Physician to St. Mary's Hospital, and Assistant Physician to the Hospital for Sick Children.

*Progressive Emaciation and Debility in a Boy, aged 18.—Absence of any Drain to account for it.—Slight Enlargement of Liver and Spleen.—Gradual Aggravation of all Symptoms.—Ascites.—Wild Delirium.—Partial Paralysis.—Death by Coma.—Post Mortem Examination.—Remarks.*

FREDERICK B., whom you will remember as an out-patient under my care, and subsequently in the Albert Ward, first came to me five months ago, complaining of gradual wasting and increasing debility, accompanied by a constant dull aching pain across the loins. He was a tall, ill-made lad, eighteen years of age, so emaciated that each rib stood out distinctly; the bony framework of the thorax seemed encased in skin alone. What struck one most, next to the loss of flesh, was the strange, dull look and manner of the boy. It was not the effect of mere languor and weakness; his intellectual faculties worked with difficulty. He answered questions intelligently, but very slowly, after an interval, as if it took him some time to comprehend what was said to him. Partly from himself, but chiefly from his mother who accompanied him, I learnt that he had suffered from large abscesses in the back five years previously; and that a year ago his feet had swelled a little, the swelling, however, quickly disappearing on his going away into the country. His principal complaint was of pain in the loins, which had troubled him constantly for the last two years. This had become worse latterly, and he had wasted rapidly. A careful examination of the chest disclosed no morbid signs of any kind. The abdomen was found considerably distended by flatus; no fluid could be detected there. There was slightly increased dullness over the region of the liver, and still more over the spleen, but no distinct tumour could be made out. The distension of the abdomen, however, prevented satisfactory examination in this respect. There was no tenderness anywhere. The urine was examined and found free from albumen, of normal specific gravity, and lithatic; under the microscope, it showed no casts or abnormal deposits of any kind. The boy was affirmed by his mother to be exceedingly industrious and steady, and the mainstay of the family. He had had no cough or expectoration, or diarrhoea, or acute disease—in a word, there had been no drain on the economy which could account for the extreme wasting. The tongue was clean, the pulse quiet, the skin cool, and the appetite moderately good. It was clear, at any rate, that the emaciation was due to defective supply, not to excessive consumption. The fault was that the tissues were not built up, not that they were too rapidly destroyed. The only deviation from the normal condition which could be detected in any organ was the slight enlargement of the liver and spleen; and the inference was that the interruption to nutrition was due to some fault there. The history of lumbar abscesses and prolonged suppuration pointed to amyloid infiltration as the most probable morbid condition, and the slow progress of the disease, the malnutrition without loss of appetite or marked cachectic look, and the tympanitis, all tended to give support to this conclusion; while, on the other hand, cirrhosis and malignant disease seemed almost excluded by the age of the patient, and the general symptoms and history of the case.

The treatment adopted was the administration of cod-liver oil, and iodide of potassium with steel. In spite of medicine and nourishing diet, however, the patient gradually became more emaciated, and at the end of three months' time, he staggered in his walk, and was more vacant and dull. The belly had become more distended, the superficial veins very conspicuous, and fluctuation was distinctly perceptible in the flanks. The spleen was now greatly enlarged, but no increase of dullness or hardness could be detected in the hepatic region. The urine had been constantly examined, but was always found of normal specific gravity, free from albumen or sugar. No casts or abnormal bodies of

any kind could be seen under the microscope. At this stage, being quite unfit to attend longer as an out-patient, the boy was admitted into the hospital under the care of Dr. Sieveking. A few days after his admission, he twice passed a considerable quantity of blood with the urine, but this did not recur, and the urine remained clear, showing under the microscope only a few blood-cells and crystals of oxalate of lime. Three weeks later, he lay helplessly in bed, constantly moaning, and frequently moving the left arm and the head with a succession of spasmodic jerks. He occasionally answered questions correctly, but very slowly, and usually merely replied "yes, sir," "yes, sir," "yes, sir," which he would go on repeating again and again many times. He complained, however, of pain in the left hypochondrium, where was the large splenic tumour, and of excessive thirst. Then he went on, "Mayn't I get up, sir?" "Mayn't I get up, sir?" over and over again, quite regardless of the reply. The tongue had become dry and very red, and coated with brown fur in the centre, the pulse faster (118), and he passed his feces under him, but his appetite still remained good, and he took food freely. The signs of obstruction to the portal circulation now became more marked, the abdomen being tightly distended with fluid, the superficial veins swollen and tortuous, and the lower extremities highly oedematous. The skeleton framework of the thorax and upper extremities, reduced to the last stage of emaciation, showed in strange contrast to the huge swollen body and legs. There was no trace of jaundice at any time. A thick crop of acne appeared on the face and remained throughout.

During the next three weeks all the symptoms became intensified. The patient no longer answered questions, but seemed dimly to comprehend them, and pointed to the right side of his head as if he had pain there. He was constantly muttering, moaning, and calling out, and jerking his head and left arm; his tongue became perfectly dry and brown; sordes accumulated on the lips and teeth. At length he became so wildly delirious that his shrieks and groans disturbed patients even in the next ward, and he was removed into a separate room in a secluded part of the hospital. A few days later, he was lying on his back, unconscious, moaning faintly, the right side paralysed, and the left arm and leg moving with slight spasmodic jerks. The pupils were widely dilated, and insensible to light. This condition deepened until he died comatose a day or two afterwards.

At the *post mortem* examination, the liver was found in a state of the most extreme cirrhosis, contracted, small, and its surface studded over with projections from the size of a No. 4 shot to a marble. The prominent tubercles were soft, consisting of the proper liver-substance more or less altered, the shrunken part between being whitish, semi-translucent, and almost cartilaginous in appearance. On section, the cut surface exhibited a curious spotted look, small islands of yellowish-coloured liver-substance implanted in a mass of whitish glistening tissue, which formed the great bulk of the organ. When examined first under the microscope, the liver-cells were seen to be fatty, and loaded with bile-pigment. A thin section, hardened in chromic acid, showed a very advanced condition of cirrhosis; the fibrous tissue was seen passing in broad massive bands between the compressed lobules, or groups of lobules, while from these larger bands branched smaller ones, spreading into the lobules, and forming areolæ of various sizes. Some of those enclosed by the broadest bands contained numerous cells; others in the finer portion of the network one or two only; and others, again, the mere granular *débris* of cells. The spleen was enormously enlarged, congested, and hard, but free from any morbid deposit. The kidneys were congested, and the capsules rather adherent, but otherwise healthy. There was an unusual quantity of dark pigment over the surface of the parietal peritoneum about the pubic region. The pancreas was dark-coloured, and unusually hard. The bladder was greatly congested near the urethral orifice, probably marking the site of the former hæmorrhage. The abdominal cavity was full of reddish serum free from lymph or pus. The base of the right lung was in a state of red hepatisation, and the left congested. There was no tubercle anywhere. A few minute echymoses were observed under the arachnoid, which was slightly opaque. But there was no other lesion of the brain, and no trace of amyloid changes in any organ.

REMARKS.—The interest of this case lies chiefly in the obscurity in which it was involved during life, and in the fact that so extreme a degree of cirrhosis was developed at such an early age; but there are several points in addition which illustrate with unusual clearness the pathology of interstitial hepatitis, and especially as to the mode in which death is produced. The mystery which enveloped the exciting cause was eventually cleared up. The mother confessed that her son took regularly a considerable quantity of drink when in work, and especially gin. It appeared, from her statement, that the labourers in the brick-fields share the popular delusion, and believe that a large quantity of stimulant is necessary to enable them to encounter the fatigue and damp

incident to heavy work amongst the wet clay. Accordingly, it has become the recognised custom for each man to put aside a certain proportion of his wages every week for the purchase of this necessary; gin being the favourite liquor, taken, as a rule, without any dilution. Hence, after all, the case turned out to be one of genuine alcoholic cirrhosis—true gin-drinker's liver; and when these circumstances are known, there is nothing extraordinary in the fact itself that a youth of eighteen should have extreme cirrhosis. The reason why it is so rare in early life is no doubt because spirit-drinking is a vice which is naturally also rare in youth. If the cause were in operation, the effect would be as readily produced upon the liver of a child as upon that of an adult. The case affords further proof that it is not so much the quantity of alcohol imbibed which determines cirrhosis, as its degree of concentration. The experiments of Dr. Percy showed that alcohol poured into the stomach is instantly absorbed, and is found abundantly in the liver in the course of a few seconds; and Dr. Budd pointed out that cirrhosis is usually the result of drinking neat spirits on an empty stomach. We constantly meet with men who imbibe large quantities of wine and beer, and spirits freely diluted, who, although they suffer from other consequences of intemperance, never have cirrhosis. The truth is, I believe, that dilute alcohol, although a fruitful source of general fibroid degeneration and other morbid changes, dependent upon its constant presence and influence in the blood, does not cause genuine cirrhosis of the liver. Wine- and beer-drinkers escape the disease, because the solution of alcohol they take is never above a certain strength. It is stronger alcohol which excites active congestion around the portal vessels in the liver by direct contact, just as it excites congestion of the stomach; the dilution of it to a certain degree removes its irritant character. Now, Sir William Jenner has shewn that mechanical congestion of any organ produces induration of its substance as a regular and constant result; interstitial exudation of lymph takes place, which is converted into fibrous tissue. And I think this proposition might be extended to long-continued chronic congestion of any kind. We see this increase of fibrous tissue as a result of chronic congestion produced by an irritant, and not mechanically, in the case of gout, where the gouty poison causes fibroid degeneration of the kidney, and fibrous thickening round the joints and in the tendons and ligaments. And we may have similar results from the poison of alcohol acting on the liver, the kidneys, and even the lungs. Whether the congestion thus set up gives rise to fibroid growth by causing interstitial effusion of lymph, or whether the presence of vitiated blood in excess stimulates the connective tissue to increased proliferation, is yet uncertain. One point, however, seems to me clear, and that is, that in this case of hepatic cirrhosis, as in cirrhosis of other organs, there is an actual increase of the fibrous element. In the instance before us, the amount of connective tissue was far too great to allow the conclusion that it was merely the aggregate resulting from the compression of the normal fibrous network, by the destruction of the true liver-tissue between the interlobular sheaths which are thus massed together, as suggested by Dr. Lionel Beale. Fresh material must have been added to make up the massive bands pervading the whole structure.

Another feature of interest exhibited by this in common with most cases of cirrhosis was the complete absence of jaundice throughout.

The fact that nearly the whole of the secreting tissue of the liver may be destroyed, and yet no trace of bile appear in the blood, attested as it is by innumerable instances, affords conclusive proof that the colouring matter of the bile, at any rate, is elaborated in the liver, and that the office of that organ is to make it, not merely to eliminate it from the blood in which it pre-exists; otherwise the most intense jaundice would follow the destruction of its active tissue. Jaundice, then, must be a consequence of some error in the chain of physiological action later than the formation of bile in the liver. The bile must first be manufactured; it appears in the blood because it is not disposed of in the normal manner. This may be due to one of two causes; either the passage out by the biliary ducts into the duodenum may be prevented by mechanical obstruction and the bile therefore absorbed into the blood, or bile may be secreted in such excess that a portion of it is absorbed by the hepatic capillaries under the increased pressure. The former we see constantly in operation in the case of tumours pressing upon the ductus choledochus, or in occlusion of the ducts by calculi. The latter is probably the mode by which jaundice is produced by fright and anxiety. A third cause may come into action in some cases, viz., disturbed metamorphosis, or consumption of bile-acids normally absorbed into the blood, either in the liver or in the intestine, and transformed into pigment to be cast out as colouring matter of the urine. This view is forcibly advocated by Frerichs, but can hardly be accepted as established; and there is one circumstance which is sometimes observed in certain diseases of the liver which shews that it is not the sole cause in ordinary cases, viz., that, although nearly the whole

liver-tissue may be destroyed by cirrhosis or malignant disease, and therefore a very small quantity only of bile be formed, yet, if any obstruction to the outflow arise by reason of increased pressure on the ducts from increase of morbid growth, jaundice at once follows. Now, why should jaundice follow the introduction of such a small quantity of bile-acid into the blood in these cases, when it does not follow the introduction of a larger quantity there in the normal condition? We know no reason why full transformation should not take place as well in one case as in the other. But to return to the example before us. A little bile was secreted, as shewn by the yellow staining of the lobules, and the small quantity formed passed out by the ducts, which generally remain sufficiently pervious. If, however, as sometimes occurs in very advanced conditions of the disease, the ducts be compressed by the new connective tissue at their origin at the circumference of the lobules, slight jaundice ensues, provided the quantity of bile formed be sufficient to give a perceptible tinge to the tissues and secretions.

The curious condition of the parietal peritoneum has not, as far as I am aware, been recorded before in the case of cirrhosis. Deposit of pigment, in large quantity, in the liver, spleen, brain, kidneys, and other organs, is met with after death from intermittent fevers. It appears still further to be specially associated with congestion of the spleen. In the present instance, the deposit occurred in connection with the same condition of the spleen. The relation between the two is still obscure—but the fact of the coincidence is worthy of note.

The gradual loss of flesh, progressing to the most extreme emaciation, reached at the time of death, is more easily explicable by physiological laws. *The patient, in fact, died of starvation.* Even in temporary arrest of the function of the liver, as in simple jaundice, there is rapid loss of flesh, and often an intense craving after food. And where there is permanent and extensive destruction of liver-tissue, emaciation is always extreme. This seems to be due to several causes. First, there is the want of bile to mix with food in the intestine, and render certain portions of it fit for absorption and assimilation. Secondly, the nutriment which is absorbed and actually enters the portal veins, passes through the liver with great difficulty or not at all, owing to the obliteration of the lobular capillaries, and can only partially enter the general circulation by means of the few new direct channels developed between the portal and hepatic veins, and the normal pre-existing anastomoses between the portal system and the vena cava. But, perhaps, the most potent cause of all in producing wasting, is the arrest in the formation of glycogen. Whatever the special office performed by the animal sugar in the economy, whether it be burnt up in the lungs, evolve force in the muscles, or be consumed in other tissues, there can be no doubt whatever that the part it plays is one of the highest importance. The simple fact that the largest organ in the body is constantly engaged in preparing it, is a sufficient proof of this. Now, we know, in the case of diabetes, that if the sugar formed by the liver be of imperfect quality, and for this, or for some other reason, be not used up for its proper purpose, the fat of the body is rapidly absorbed to replace it as fuel, or to generate force in some form. And there can be little doubt that, in the same way, when the quantity of sugar is deficient, or when it is absent altogether, the fatty tissues are burnt up in the like manner. This result of the arrest of this function of the liver, and the important bearing which it must have upon the course of diseases such as cirrhosis, have not hitherto, I think, engaged sufficient attention. There were, then, three great causes for the emaciation; viz., the want of bile to digest certain food; the obstruction to transmission of nutriment from the portal vessels to the general circulation; and the non-production of glycogen, with the consequent absorption of fatty tissue to replace it. And we find, accordingly, that, in the present instance, the fat had entirely disappeared, just as it disappears in prolonged starvation.

I have shewn how starvation practically did take place; and I wish to draw your attention to the identity of the symptoms with those observed in cases of starvation from want of food. The dullness of intellect, the indifference, the languor, the staggering gait which accompanied the gradual loss of flesh in the earliest stages, are exactly the symptoms met with in the early stages of privation from food. The delirium, the restless movements, the twitchings of the limbs, the hemiplegia, the paralysis of the sphincter, the brown dry tongue, the weak rapid pulse, and the death by coma at last, correspond with equal fidelity. Nothing was found in the brain after death to account for the cerebral symptoms. They were not due to cholæmia, since there was no bile in the blood, even if the experiments of Frerichs and the history of chronic jaundice did not throw extreme doubt upon the theory that it gives rise to evil effects on the nervous system. The delirium and paralysis, and convulsions, were due to deficient supply of nutriment to the brain and cord; the ultimate cause of death was starvation of the tissues.

## ON MARASMUS AS AN OCCASIONAL CONSEQUENCE OF ENTERIC FEVER.\*

By T. CLIFFORD ALLBUTT, M.A., M.D. Cantab., F.L.S., etc.,  
Physician to the Leeds General Infirmary; Lecturer on Practice of  
Medicine, etc.

WE not uncommonly meet in practice with cases of general wasting which do not tend quickly to death, but which, on the other hand, are almost incurable. We can find no organic disease, but the patient loses flesh and turns sallow, until, when stripped, he seems almost a living skeleton. In this state, he may survive many years, unfit for exertion; eating food and getting no good from it; spending his substance upon physicians, and growing thereby no better, but rather the worse. Such cases of wasted, sallow, feeble frames, without any definite disease, must have occurred in the practice of many or most of us. It was not until several of these cases had presented themselves to me as riddles which had to be given up, that I ventured to guess at a solution which may be true, at any rate, for some of them.

It so happened that, in more than one instance, on writing the notes of the patient's previous history, the symptoms seemed to date from a precedent attack of enteric fever. Up to the onset of this illness, the patient had enjoyed good health; but, after it had passed by, he remained feeble, his convalescence was protracted, and, although perhaps he did regain flesh and strength in some considerable degree, yet in a few months more this new flesh fell again from his bones, and left him wan, wasted, and spiritless. Thus my attention was drawn to the question of the connection between such a marasmus and a precedent attack of enteric fever; and this question once raised, the answer to it does not seem far to seek. I am rather surprised, on turning over the leading treatises on enteric fever, to find that the chance of so severe an abdominal disease permanently affecting nutrition, has not presented itself to the writers; nor do I ever remember to have heard this disease suspected of doing more than temporary mischief. But when we look at the parts affected by this fever, when we remember how severely it falls upon a large part of the absorbent surface of the intestine, and upon the glands of the mesentery, it would seem likely, *a priori*, that in some instances absorption might be permanently interfered with.

I shall now proceed to read short notes of five cases of this kind which have occurred in my practice since my opinions on the subject were formed, and in which careful and particular inquiry was made from the present point of view.

CASE I.—Miss H. R., aged 25, had always enjoyed good health until she had a severe attack of enteric fever about two years ago. Latterly, she was believed to be phthisical, and had consulted many medical men from that point of view. She came to me on May 6th, 1870. She had lost flesh greatly, so that her bones stood out in almost startling relief; the eyes were sunken, and the complexion sallow. She had no night-sweats, and the temperature, at 11.30 A.M., was only 97.6 deg. Fahr. The tongue was clean, and the appetite was fair. Meat agreed best with her, and mutton chops in particular; fatty substances disordered her stomach, and made her "bilious." She was very liable to flatulence, though the abdomen was rather sunken than prominent, and she was much annoyed by loud rumblings in the bowels. She was unable to give much account of the appearance of the motions, but these and the catamenia were regular. This wasting in spite of the ingestion of fair quantities of food had been coming on for about a year, or probably for a longer time. Her convalescence from the fever, in fact, was delusive. Slowly she seemed to improve for about six months, then she remained at a standstill for a while, and, a few months later, the wasting steadily set in. I examined this patient most minutely; during the time she was under my observation, I saw her at home in bed, and left no organ without investigation. Every part, however, seemed quite normal, so far as I could tell. I tried various remedies, including pancreatised fats, but without success; and she left me for another adviser.

CASE II.—On July 8th, 1870, Samuel Jennings came under my care at the Infirmary for a like train of symptoms. He was twelve years of age, of good family history, and himself had excellent health until two years previously. He then suffered from typhoid fever severely; he seemed to make a fair recovery at the time, but had scarcely realised his recovery when he began to fail again in flesh and strength. On admission, he was extremely wasted and sallow. No organic disease could be made out anywhere; his temperature was slightly below the normal, his appetite was fair, and he had no night-sweats. The urine was normal, and the bowels regular. He remained under treatment by

pancreatised oil, ox-gall, and other remedies for a month, when we lost sight of him.

CASE III.—Mr. Lewis C., aged 18, consulted me on October 11th, 1870. In the previous March, he was convalescent from a severe attack of enteric fever, and went to the sea-side, where for a while he recovered strength. In June, however, he was evidently falling off again in both flesh and strength. He gradually became, as he was when I saw him, extremely wasted and sallow, although his appetite remained fair. Meat seemed to agree best with him. Like Case I, he complained much to me of loud rumblings in the belly. The motions were reported to be natural, though somewhat confined; except that he was liable to occasional attacks of diarrhoea. The temperature was natural, or a little under the mark; and he had no night-sweats or cough. The pupils were dilated; the pulse slow and weak. No organic disease was to be discovered in the lungs or in any other organ. Treatment here failed, as in the preceding cases, and I lost sight of the patient.

CASE IV.—Mrs. S., aged 50, had always enjoyed good health, and had passed easily through the change of life eight years before. Three years ago, she had a severe attack of enteric fever, and really never picked up her flesh and strength as before. Latterly, she had lost flesh greatly, and appetite, also, in some degree. Sometimes she loathed all food, but not generally. She ate mutton chops better than anything else. The urine and all the organs were normal; temperature also normal. She was sallow and much wasted. The bowels were rather confined. Mrs. S. is still under my care, but remains in much the same state.

CASE V I include with some hesitation, as the interval between the wasting and the attack of fever was a long one. Mr. Harry T. was brought to me by his father on December 17th, 1870, from a distance; he complained of wasting and loss of strength. His health was good until he had enteric fever, at the age of eleven. He is now eighteen. He apparently recovered from the fever, and remained well for three years. He then began to fall off; and, at the age of fifteen, his health had suffered very seriously, and he became wan and extremely wasted. Of late, his appetite had fallen off in some measure. After any error of diet, however slight, he suffered greatly from flatulence and rumbling in the bowels. He never had diarrhoea. His temperature, urine, and all organs were quite normal.

To these cases, I would add another. A lady, Mrs. L., has been long under my care for extreme marasmus, sallowness, and loss of strength. All her organs are healthy, and her temperature is normal. She has a fair appetite, but can only eat meat with comfort; any error from the plainest meat diet is visited upon her severely with so-called bilious symptoms, and occasional diarrhoea. The bowels are rather confined as a rule, and the motions large and pasty. All this wasting and debility date from a severe attack of diarrhoea, with blood and slime, which she calls dysentery. This attack occurred about ten years previously, when she was under homœopathic treatment. It was many weeks before she recovered; and she seems at that time to have found much benefit from fractional doses of corrosive sublimate. All her organs remain healthy up to the present date, so far as can be made out. Mrs. L.'s symptoms bear a strong resemblance to those observed in the preceding cases.

If we now look at these cases together, we find that they all agree in these points: (1) in wasting, which is not due apparently to febrile action or to organic disease, but—as it would seem—to defective nutrition; and (2) in the history of a previous illness, which fell with severity upon the intestinal canal. It appears, farther, that the innutrition consists rather in the lack of digestive power over fats. There is no tendency to absolute starvation; but, in the subcutaneous tissue, there is an utter absence of fat, and, so far as we can tell, all parts and organs have lost their adipose investment. Stomach or meat digestion, on the other hand, seems fair, and many starchy substances likewise seem to be fairly assimilated. In all cases, light puddings, corn-flour, arrow-root and the like, seem to have been digested, not only with impunity, but with advantage. In the cases where I could examine the stools, I found large pasty evacuations, but no separated fat—no diarrhoea adiposa; so that I assumed that the biliary and pancreatic secretions were duly poured into the intestine, and that they duly emulsified the fats. But the fats, nevertheless, if taken, turned rancid in the intestine, causing so-called biliousness, and, moreover, they failed to find their way into the circulation. It seemed, therefore, likely that the fault lay in the machinery of absorption. That surface of the tube which is devoted to this purpose, suffers greatly from the ulcerative process in enteric fever; and if this be partial in its distribution in the bowel, such cannot be the case at any rate with the associated system of mesenteric tubes and glands, all of which are involved in irritative action, and are likely, in extreme cases, to suffer permanent degeneration in their

\* Read in the Medical Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

texture. If we feed a rat on tallow, and then open the abdomen, we shall see that the whole of the mesenteric system is full of finely separated and emulsified oil-particles on their way into the blood; and this simple experiment will demonstrate to us the probable result of blocking up this system by cicatrization or destroying it by inflammation. The slow and often incomplete convalescences from enteric fever, and the liability of its victims to subsequent disease, such as phthisis, is well known. Tubercle in these patients may arise from absorption of cheesy matter from the mesenteric glands into the blood-current; but catarrhal phthisis, and other like sequelæ, may be due to the imperfect restoration of the fat-collecting machinery. It is to this cause of incomplete convalescence, of marasmus, or of chronic disease as common consequences of enteric fever, that I wish to-day to call the attention of clinical observers. Pathologically, I am not in a position to offer any evidence; but I shall be much indebted to any of my hearers who will secure for me the intestine and mesentery from any case of chronic disease which may seem to have had such an origin as I have ventured to indicate.

## ON CATHETERISM OF THE EUSTACHIAN CANAL.

By R. HIBBERT TAYLOR, M.D.,

Consulting Surgeon to the Eye and Ear Infirmary, Liverpool; and formerly Lecturer on Ophthalmic Medicine and Surgery in the Royal Infirmary School of Medicine.

CATHETERISATION of the Eustachian canal is no new invention, but one which, like many others in medicine and the arts, was known and adopted in former times, fell into disuse, and has been again revived and practised in our own days.

Upwards of a century ago, a postmaster of Versailles, named Guyot, afflicted with deafness, and probably having some knowledge of anatomy, conceived the idea of treating it by the injection of fluids into the faucial orifice of the Eustachian canal. To effect this, he introduced a bent sound through the mouth, and by this means succeeded in at least washing the entrance of the canal, for it is not likely that he could do more by this method of proceeding, and so relieved his deafness. An account of this invention was submitted to the Academy of Sciences in Paris in the year 1724, but it does not appear to have led to any further result.

Twenty years later, an English surgeon named Cleland, who describes himself as "Surgeon to General Wade's Regiment of Horse", revived the practice, and gave it an important modification by introducing the catheter through the nasal passages instead of the mouth. The instrument which he employed, and which is figured in the *Philosophical Transactions* for 1741, p. 848, resembles a small catheter, and has this inconvenience, that it is pierced with lateral eyes at its distal extremity, which would give to any fluid injected through it a direction different from that of the Eustachian canal. Although Cleland describes this instrument and the mode of using it, and a syringe which is to be adapted to it, he does not state that he had used it himself with success. His statement regarding it is as follows. "If, upon trial, the Eustachian canal should be found to be obstructed, the passage is to be lubricated by throwing a little warm water into it by a syringe joined to a flexible silver tube, which is to be introduced through the nose into the oval opening of the duct, at the posterior opening of the nares, towards the arch of the palate. The pipes of the syringe are made small, and of silver, to admit of bending them as occasion offers, and for the most part resemble small catheters."

The surgeons of Montpellier, according to Itard, who wished, on the recommendation of Sauvages, to make use of Cleland's instruments, could not succeed in injecting the canal until they had made some modification in the catheter, probably by substituting a single opening at the extremity for the lateral eyes which Cleland describes. Antoine Petit, in the edition of Palfyn's *Anatomy* which he published in 1753, does not mention either the memoir or the operation of Cleland; and he criticises the instrument of Guyot as being incapable, as he employed it, of reaching the objects which he proposed.

In 1755, Mr. Jonathan Wathen, surgeon in Devonshire Square, London, published in the *Philosophical Transactions* a short memoir entitled "The Method proposed to restore the Hearing when injured from an Obstruction of the Tuba Eustachiana". In this communication, he remarks that Guyot's proposal to pass a catheter into the Eustachian canal by the mouth is impossible of execution, as any one may convince himself who takes the trouble to examine into the matter. "Convinced of this," he says, "M. Petit proposed, and that learned and skilled anatomist Mr. John Douglas demonstrated, the possibility of passing the probe, etc., through the nose into the Eustachian tube;

and this he has continually shown to those who have attended his public lectures; and to him I freely acknowledge myself indebted for the hint by which I was incited to make trial on the living subject of an operation of so much importance to mankind." Wathen made use of a silver pipe of about the size and length of a common probe, to which an ivory syringe was fitted when required. It is somewhat remarkable that Wathen in his paper makes no allusion to Cleland, whose memoir on the same subject was published in the same learned journal only fourteen years previously; but such oversights, whether by accident or intention, are not unknown even in our own times. Wathen appears to have had opportunities of confirming by his own observations those of Tulp, Valsalva, and Boerhaave, regarding deafness induced by enlargements of the tonsils. He had also noticed a form of deafness brought on by cold and congestion of the Eustachian canal; and further, in a *post mortem* examination of a man aged 35, who had been deaf during several years as a sequela of cold, and who died of variola, he could not discover any unhealthy condition of the ears, with the exception of obstructed Eustachian canals, induced by the presence of thickened mucus. Building upon these facts, he attempted to inject the Eustachian canals in cases of deafness generally; and of six persons upon whom the operation was practised, five are said to have received more or less benefit from the treatment. The details of one of the most remarkable are as follows. A. had been deaf for eighteen years, and had also an affection of the sight, which consisted in the appearance of a number of different colours floating continually before his eyes. The deafness was so great that he could hear only one person, with whose voice and appearance he had long been familiar. This patient had been subjected to a variety of treatment, more expensive than efficacious, which had induced salivation and profuse perspiration; but, excepting some slight changes, he had remained in the same condition till February 1st, 1754, when he placed himself under the care of Mr. Wathen. After the first injection made into the Eustachian tube, he heard his own voice, which he was previously unable to do. This injection was followed by four others, at intervals of one or two days. The progress towards amendment continued; and this remarkable phenomenon was induced: when the ear was subjected to sounds as loud as it was accustomed to bear before the deafness commenced, the organ experienced a jarring sensation, a sort of painful grating; and the same thing was observed when the patient spoke. However, he could now hear the voice when moderately elevated, and was able to take part in an ordinary conversation, provided that the room was quiet. It is worthy of remark, that the affection of the sight disappeared after the second injection of the Eustachian tube. This case is certainly remarkable, so far as it goes, considering the long duration and great amount of the deafness. The phenomenon adverted to, with regard to the jarring effect of ordinary sounds upon the restored organ, is one with which all are now familiar who have had frequent occasion to treat diseases of the ear.

The following case, taken from Itard's treatise on *Ear-Diseases*, is both interesting and instructive, although the treatment in this instance was not confined simply to injection of the Eustachian canal.

"Dorothy Paulet, a servant-girl in a farm near Paris, was sent to me by some charitable persons to be treated for deafness, which had reduced her to misery, and rendered her incapable of continuing her service. It was necessary to shout very loud and distinctly into her ears in order to be heard. She had been treated for a long time, and without benefit, by another practitioner. The external meatus was healthy; the membrane of the tympanum did not present any notable change; and the air, when passed into the Eustachian tube in the ordinary manner, entered the ear; for the patient was conscious of a painful sensation within the organ. In this state of things, the diagnosis was very obscure; and the more so, that there was nothing in the patient's constitution or in the history of her antecedents which could throw any light upon the cause of the deafness. It had commenced two years previously, and had continued to make rapid progress. However, it was necessary, as the girl said, either that she should be cured, or else die of hunger. A motive so urgent induced me to undertake, or rather to attempt, a very hazardous treatment. Moxas upon the head, galvanism, cupping upon the shoulders, strong purgatives, an otitis induced by irritating injections, had no other effect than to weaken and still further discourage this poor girl. At length I decided, almost against myself, to try perforation of the membrane of the tympanum; and I commenced with the right ear. The injection made the next day did not pass through; and it was in vain that I flooded the external meatus by means of a tube of the diameter of a writing-quill, to which a syringe was attached. Three days having been passed in these vain attempts, I then tried to press the injection in another direction—viz., from within outwards through the Eustachian canal. This effort succeeded, for at the second sitting the liquid came through the external

meatus. It was only at first a sort of transudation; but the next day the water ran drop by drop, and then in a continued jet from the external ear, to the great delight of Dorothy, who perceived almost immediately that she heard much better. The same means, continued during a fortnight, improved considerably the hearing on this side. The result was still more complete on the left side—where, indeed, the deafness was a little less intense. It was not necessary to inject from the faucial extremity of the Eustachian canal. At the third attempt, the liquid flowed from the internal ear into the nostril; and, to crown our happiness, the wound made in the membrane of the tympanum on that side closed up completely, when the injections were discontinued, after having effected all the good which they could do. To prevent the recurrence of this deafness, I advised the girl to learn to smoke, and to force the tobacco-fumes into the ears by carefully closing the mouth and nostrils."

The following case, also from Itard, shows how the hearing may be improved by the persevering use of injections through the Eustachian canal.

"A lady of Bordeaux, thirty years of age, of lymphatic temperament and very subject to attacks of catarrh, lost her hearing almost entirely, after having suppressed by sea-bathing a leucorrhœal discharge which had existed from puberty. Having been consulted by means of a written statement of her case, I prescribed mild emetics, repeated every fortnight; resinous purgatives; applications of warm water to the region of the uterus; and finally a blister between the shoulders. These means dispelled the deafness entirely, but only for a few months; at the end of which time, although the leucorrhœa, which had been recalled by the treatment, was as abundant as ever, the deafness returned as before, and accompanied with severe symptoms, which, however, varied in degree; and as these disappeared, there were glairy discharge, thickness of the voice, and snuffling. This lady came to Paris to consult me in the spring of 1813. On examining the external meatus, I found it so filled with cerumen that I hoped to restore the hearing by the simple removal of this obstruction. In this, however, I was deceived, for it did not produce even a slight improvement; and the deafness was such, that Mad. — could only hear by means of an ear-trumpet. The treatment which I had advised during the first attack of this ailment had been repeated unavailingly during this relapse, which decided me to have recourse at once to injection of the Eustachian canal. I employed warm water only, which I first injected into the Eustachian canal of the right ear. The liquid passed in; but the deafness, instead of being lessened, was so much increased that the sharpest cries and the loudest noises could scarcely be perceived. I was not much annoyed at this result, with which I was already familiar, and attributed it to reflux into the cavity of the tympanum of the thickened mucus which obstructed the Eustachian canal. By next morning this increase of deafness had spontaneously disappeared, and Mad. — thought that she was even somewhat better—a fact which was no longer doubtful when a second injection had been made. The third produced a still greater change. The sounds of an ordinary voice, provided it was directed towards the concha, were distinctly heard without the aid of a trumpet; and finally, at the end of twelve days of this treatment, the hearing on the right side was completely restored. In order to confirm the cure, I employed about an equal number of injections with sea-water heated to the temperature of an ordinary bath, and forced into the canal in a continuous stream by means of a syringe. I wished next to operate upon the left ear, but encountered an insurmountable difficulty in the narrowness of the left nostril, towards which the septum of the nose was so strongly inclined that it was impossible, after having with difficulty introduced the sound, to pass it onwards so as to place the beak of the instrument in a horizontal position. To escape this difficulty, I proposed to perforate the membrane of the tympanum, and inject the internal ear from without inwards. The patient having consented, the operation caused little pain; but it was not so with the injection, although made with tepid water only. Vertigo came on, with headache and a certain amount of fever. I was obliged to discontinue the injections for six days, although they had only been made twice, and the liquid had not appeared beyond the orifice of the Eustachian canal. When, after the disappearance of these symptoms, I wished to renew the treatment, I perceived that the membrane of the tympanum had healed up; and an injection which I made, in order to assure myself of the fact, left no doubt regarding it, for the water did not penetrate beyond the auditory canal, and did not induce any pain in the ear. This new disappointment made me despair of effecting a cure in this ear; and so I abstained from any further attempt, which, indeed, the patient was little disposed to bear, as the hearing with the right ear was now so complete."

Professor Trötsch of Würzburg, who has written a treatise on diseases of the ear, as commendable for its brevity as for its clearness

and the amount of information which it contains, says that he is in the habit of blowing air through a catheter into the Eustachian canal as a means of diagnosis in certain affections of this tube and of the inner ear; and from the sounds produced during the passage of the air he is able to form some judgment as to the condition of these parts. He employs the same method also as a means of cure, and considers it to be useful in clearing the canal of mucus or any other removable obstruction. He says, further, that he has never observed any injury follow the blowing of air into the cavity of the tympanum, but considers the benefit of the air-bath to be in general of a temporary character. The catheter he regards as useful also as a means of applying other remedial agents to the inner ear, as certain gases; and also for the introduction of wires, to cure by electricity. Trötsch objects to the use of fluids for the purpose of injection into the cavity of the tympanum, as likely to prove injurious; and recommends the employment of air and gases only.

Toynbee does not believe in the utility of the catheter as a means of diagnosis in affections of the inner ear, but recommends a "fad" of his own, in which the patient, closing his mouth and nose, attempts to inflate the Eustachian canal; while the surgeon uses a tube named an "otoscope," one end being inserted into the ear of the patient, and the other into that of the operator. As a means of cure, he thinks with Trötsch that the catheter may be used in clearing out the Eustachian canal; but he conveys a caution to use the remedy with gentleness, as fatal effects have followed the sudden and forcible introduction of a stream of air into the cavity of the tympanum. Toynbee relates a case, occurring in his own practice, in which inflation of the Eustachian canal by means of a catheter, in conjunction with other means, effected the cure of deafness.

Wilde of Dublin, in his treatise on *Diseases of the Ear*, says that he uses the Eustachian catheter as a means of diagnosis when the patient is unable, by closing the mouth and nostrils, to inflate the membrane of the tympanum. He does not believe that washes or vapours, when introduced through the catheter, ever reach the cavity of the tympanum; and as to the treatment of what is termed "nervous deafness" by injections of ether or anything else, he has no faith in it.

As to the mode of introducing air into the Eustachian canal, Trötsch and Wilde employ an "air-press"—a machine in which the air, after being forced into a strong cylinder, is gradually introduced by turning a stopcock into a tube communicating with the catheter, and so into the Eustachian canal. This mode requires the use of a rather complicated apparatus, and, besides, is open to the objection of possibly admitting a strong current of air to flow suddenly into the ear; and, if the point of the catheter slip from the opening of the canal, the air may be driven into the cellular membrane of the throat or directly into the larynx—an accident which is supposed to have happened in one of the fatal cases which occurred in London some years ago.

The cases above recorded as having occurred in the practice of Wathen and Itard, if worthy of credit—and I see no reason why they should be called in question—sufficiently attest the benefit which may in some instances be derived from injection of the Eustachian canal with tepid fluid, and appear to controvert the statement of Wilde that fluids so introduced can never reach the cavity of the ear. They afford, at all events, sufficient grounds for making trial of this mode of treatment in any case in which there is reason to suspect occlusion of the Eustachian, as evidenced by the patient's inability to inflate the membrane of the tympanum. My own experience—which, however, has not been very extensive in catheterism of the canal—would certainly incline me to this decision. I have observed benefit to result in several instances from inflation of the Eustachian by blowing air into it through a catheter. The introduction of the instrument into the faucial orifice of the canal is by no means difficult, requiring, no doubt, the possession of a certain amount of dexterity, which, however, lies within the compass of almost any one to obtain; and, as I think the air is best introduced by applying the mouth to the wide end of the catheter and blowing through it with varying force, all complicated apparatus is thus dispensed with, and the operation is neither alarming to the patient nor unreasonably difficult to the operator. I have not myself tried the injection of water or any other liquid into the Eustachian by means of a catheter; but I see no valid reason why it should not be done, if conducted with caution; and, by means of a moderate sized syringe fitted by its nozzle to the wide extremity of the catheter, it could be effected without difficulty.

In conclusion, I beg to commend the subject to the consideration of my brethren in the profession. It seems to merit their attention; for a mode of treatment which, in the hands of others, has in some instances been productive of such excellent results, may not improbably, in similar cases, prove equally successful in theirs.

## ON THE PATHOLOGICAL AND THERAPEUTICAL RELATIONS OF ASTHMA, ANGINA PECTORIS, AND GASTRALGIA.

By F. E. ANSTIE, M.D., F.R.C.P.,

Senior Assistant-Physician to Westminster Hospital; Lecturer on Medicine in Westminster Hospital School; Physician to the Belgrave Hospital for Children; etc.

DURING the last three or four years my attention has been drawn to an interesting pathological and therapeutical connexion between three nervous affections which are individually reckoned among the anomalies and the difficulties of practical medicine, and which, so far as I know, have not usually been directly associated with each other in the classifications of writers on nervous diseases. I refer to spasmodic asthma, angina pectoris, and gastralgia. It is true that Kneeland some years since indicated the fact that there was some connexion between asthma and angina pectoris; but, so far as I know, no author has distinctly classified these diseases as depending essentially on neurosis of the vagus; and certainly no one has yet advanced the theory that both of them, and also gastralgia (or neuralgia of the gastric nerves), are essentially dependent on neurosis of the vagus which is of central origin, and in a large majority of cases is mainly or entirely due to inherited peculiarities of the central nervous system. Such is the proposition which I now submit to you.

In so short a communication as can alone be received by this Association, it would be impossible to bring forward sufficiently detailed evidence to establish positive proof of this doctrine; nor do I pretend myself to possess such positive proof. It will be sufficient to indicate to the members the chief of those facts which, to my judgment, make the hypothesis exceedingly probable, and certainly worth following up.

The evidence arranges itself under five sections:

1. Inferences from the known physiological functions of the vagus;
2. Evidence of the interchangeability of asthma, angina, and gastralgia, in the same individual;
3. Evidence of the pathological connexion of these neuroses with neuralgia of the fifth nerve;
4. Evidence of the common dependence of asthma, angina, gastralgia, and neuralgia of the fifth, on peculiar inherited neurotic tendencies;
5. Evidence from the similarity of effects produced by certain remedies on all these maladies.

1. As regards the physiology of the vagus, there is no need to deliver a class-room lecture to the present audience. It will be enough to remind you that, besides its other offices, the pneumogastric acts as the great afferent of sensory impressions from the stomach and from the mucous surfaces of the lungs and trachea, and as the main, if not the sole, organ of cardiac sensibility; that its ramifications form an integral part of each of the various nervous plexuses in the cardiac, gastric, and respiratory territories; and that its deep origin is placed within the medulla oblongata, and united by the most intimate connections with the sensory nucleus of the fifth nerve. There are thus *prima facie* reasons for presuming that the three neuroses, asthma, angina, and gastralgia, would all depend upon irritation of the vagus. As regards asthma, there is, I suppose, a pretty general adhesion among the best recent authorities to the theory of irritation of the pneumogastric, which is well expressed by M. Sée of Paris in an article on the Treatment of Asthma in the *Practitioner* for July 1869. As regards the pain of angina, and indeed as regards the sources of cardiac sensibility in general, there has been much dispute; but the facts seem to me to point very clearly to the belief that branches of the vagus, reinforced in the cardiac plexus by other spinal branches which come from the cervical and the uppermost dorsal cord-centres, through the medium of the sympathetic ganglia of the neck, fully account not only for heart-sensibility, but also for the curious transmission of pain in angina to the arm, the chest-wall, and the neck. The chief objection to this view has rested upon the belief that the sympathetic branches must also have a share in the production of the pain; but the idea that the sympathetic is capable of expressing sensations of pain seems to me to rest on an exceedingly doubtful basis, and to be supported chiefly by the apparent analogies of the pain of colic, gall-stone, etc., for which pains there is really a much more probable source in branches of spinal nerves. Everything in recent physiological observation seems to suggest that all the apparent cases of sensation in the sympathetic fibres are really due to branches of spinal nerves that are bound up with them. As regards angina, the only question as to which I feel much doubt is, whether the vagus centre or the cervical and upper

dorsal cord-centres just referred to are most prominently concerned in the origination of the disease; but, at any rate, it seems clear that, from the moment that serious symptoms of angina are set up, the vagus centre must be involved, since this must be the intermediate instrument of the reflex disturbances of respiration which occur during the paroxysms. On the whole, I lean strongly to the idea, which will be found expressed in the pathology chapter of my work on *Neuralgia*, that the irritative process in angina commences in the spinal centres which send branches to the cardiac plexus, and then involves the vagus secondarily, but at a very early period.

2. The second branch of the evidence that connects asthma, angina, and gastralgia, all with the same great nerve, is derived from the singular interchangeability of the three maladies. Kneeland long ago remarked that spasmodic asthma and angina were thus apt to pass the one into the other. For my own part, I can refer to several instances of the connexion between all three diseases, and would sum up the general results of what I have seen in the following terms. 1. Severe and protracted asthma nearly always becomes complicated, after a time, with symptoms which may not amount to what would commonly be called angina, but assuredly belong to the same category; and in not a few instances (I have myself seen three) asthma leads directly into declared and unmistakable angina. 2. Asthma is nearly always associated with gastralgia. It is true that the neuralgic character of the pain is very often overlooked, and it is attributed incorrectly to dyspepsia; but I have frequently had occasion to prove the fallacy of this idea, the only ground for which is, that asthmatic patients will not bear putting a large amount of food in the stomach at once. Asthmatic patients are not commonly dyspeptic in the proper sense of the word; and the epigastric pain, from which they almost all suffer more or less, requires to be dealt with as a part of the general nervous affection. 3. The chronic form of angina is, so far as I am aware, almost invariably associated with more or less gastralgia, which, as in the case of asthma, is continually being mistaken for dyspeptic pain, and treated, with very unfortunate consequences, from a gastric instead of a nervous point of view. Like asthmatics, these patients require to be fed in small meals; but nothing save harm can come of keeping them on a small total supply of nutriment.

3. The next branch of evidence for the essential interconnexion of the three neuroses of which we are speaking is derived from the way in which they are mixed up and complicated with neuralgia of the fifth nerve—a complication which, if it can be shown to occur with a certain special frequency in these diseases, would go far to trace home the *fons et origo mali* to that portion of the medulla oblongata in which the nuclei of the vagus and the fifth are found in intimate connexion with each other. Upon this point the evidence is, in my experience, exceedingly strong, and may be shortly stated thus: that, whereas neuralgia of the trigeminus is a more or less occasional complication or attendant of other neuralgias generally, it is an almost invariable complication of nervous asthma, nervous angina, and gastralgia. Of course it varies greatly in severity. It may amount, and indeed generally does, to nothing but an attack of migraine every month or six weeks; but there it is, nearly always. And, as regards gastralgia, I have seen numerous instances of its interchangeability with facial neuralgia, of which the following is perhaps the most striking. A watchmaker's assistant, aged 43, applied to me at Westminster Hospital, suffering from intermittent attacks of epigastric pain, which came on specially at times when he was exhausted from want of food, and were uncommonly severe and prostrating. After he had been under my care for ten or twelve days, these pains were abruptly superseded by violent neuralgia in the globe of the right eye and in the branches of the ophthalmic division of the right fifth nerve generally. This neuralgia was not merely severe in itself, but it ran on into secondary iritis, with destruction of the eye for visual purposes. This is the most severe case of trigeminal neuralgia complicating gastralgia that I have seen, but I have witnessed plenty of slighter ones; and, on the whole, I believe that true gastralgia, as distinguished from mere dyspeptic stomach-pain, is nearly always attended with a tendency to facial neuralgia in some form and degree.

4. In the next place, the close interconnexion of asthma, angina, and gastralgia, and their common dependence on an affection of the central nervous system, is rendered more probable by the remarkable history of inherited neurosis which the sufferers from them will always be found, upon careful inquiry, to present. This is a branch of investigation which has greatly engaged my attention; and in my work on *Neuralgia*, the results of a good many such inquiries as to the pedigree of neuralgic patients will be found. But I have not had space for everything in that work, and must probably reserve for a separate publication the remarkable facts which come out respecting the hereditary connexion of asthma and angina pectoris. Respecting

gastralgia, it has been, for obvious reasons, impossible to procure evidence of a precise and reliable character; but, as respects asthma and angina pectoris, I will go so far as to say that I believe there hardly ever existed a sufferer from one of these diseases in whose blood-relations, either of the same or previous generations, one or more examples of the other could not be found by proper inquiry; and occasionally one comes across families which seem to have been quite plague-stricken, as it were, alternately with these two maladies. And it is a singular fact that I have twice known these diseases to be the only nervous maladies that could be traced in a large family of two or three generations.

I may here properly introduce the reply to an expression of surprise which some of my audience may have on their lips, at the frequency which I ascribe to angina pectoris, which, on the contrary, has usually been considered a very rare disease. But I have already had the honour to tell this Association (at the meeting in 1868) that observation had convinced me of the error of that opinion, which arose from neglect or misunderstanding of all but the severest and suddenly fatal cases of angina; whereas there are, in fact, a multitude of cases in which the nervous affection—the cardiac neuralgia—which is the only essential portion of the disease, exists in all shades of severity, down to an exceedingly mild and trivial complaint. And my subsequent experience has strongly confirmed me in this belief, which is also expressed by some of the most careful recent writers.

5. The last, and to me personally the most interesting, link in the chain of evidence which connects together the three neuroses, asthma, angina, and gastralgia, is formed by the results of therapeutical experiment. There is one remedy which is supremely effective, where it can be tolerated, in all these three maladies; namely, arsenic. As regards angina, I may say that, since my attention was drawn to arsenic by a remarkable case published by Philipp in 1865, I have had a rather large number of severe cases to treat; but it is within the last twelve months that I have received the most conclusive proof of the power of this drug over the nervous symptoms of angina. Two examples especially illustrate this, the subjects being respectively aged 65 and 75. Each of these gentlemen was free from recognisable organic heart-disease; but there was much probability in both cases that there may have been a certain amount of ossification of the coronary arteries. Be that as it may, in both these cases arsenic, in five-minim doses of Fowler's solution three times a day, relieved the attacks very rapidly, and completely removed them in the course of about a fortnight. There had previously been daily paroxysms in each of these cases; and the elder of the two gentlemen was the more struck with the rapidity and completeness of the relief obtained, inasmuch as he was a medical man, and was, of course, thoroughly well aware of the intractability and the formidable nature of the disease. As regards gastralgia, the efficacy of arsenic was some years ago pointed out by Dr. Leared; and I have had several opportunities of proving the correctness of his statement. But more especially is it an effective remedy in that form of gastralgia which accompanies asthma. I have for many years been accustomed to the use of arsenic in asthma, and had seen great benefits produced by its tonic effect. I had also noticed, without thinking much about it, that the tendency to gastralgia, and also to facial neuralgia, was at the same time remarkably diminished; but at present I cannot regard the coincidence as accidental. In regard to the effects of arsenic upon asthma and angina, it seems proper to refer to the facts, long disputed, but now established as true, respecting arsenic-eating in Styria. It has been ascertained beyond doubt that many natives of that country eat arsenic, with very remarkable benefit to their power of ascending steep mountains. It enables them to do this comparatively without distress to breathing and circulation. There are, however, a considerable number of persons who cannot take arsenic in the doses and for the prolonged period which are necessary to make any permanent impression upon either of the three neuroses of which we have been speaking. These patients suffer such irritation of the stomach or bowels from it, that they cannot continue it. For the relief of such persons, I beg leave again to suggest a remedy that I mentioned in my paper on Visceral Neuralgias in 1868, and which I have since found very useful in spasmodic asthma, as well as in gastralgia and angina: I mean the subcutaneous injection of strychnia in very small doses, from the 1-120th to the 1-80th or the 1-60th of a grain. I would always try the subcutaneous administration before giving the remedy by the stomach, wherever it is possible to do so; but, if this cannot be done, strychnia should be given by the mouth in doses of 1-40th to 1-24th of a grain three times a day. I think there is little doubt that strychnia also has a physiological affinity for the tract of the vagus and the trigeminal nerves; also this is much feebler than that of arsenic; hence I should always recommend that the latter be tried first.

## ABSTRACT OF A CLINICAL LECTURE ON ELEPHANTIASIS GRÆCORUM.

By ROBERT LIVEING, M.D.,

Senior Assistant-Physician to the Middlesex Hospital.

GENTLEMEN,—True leprosy, or elephantiasis Græcorum, is met with in two principal forms: the first is known as tubercular, the second as anæsthetic, leprosy. The latter differs from the former chiefly, but not solely, in the fact that the cutaneous nerves are especially affected, and consequently anæsthesia of the skin forms a prominent feature of the disease. The two forms are, however, not unfrequently (about 15 per cent.) met with in the same individual.

Leprosy is common in the East and West Indies, the Mauritius, Madeira, and other semitropical countries; but it also prevails to a considerable extent in Norway, Denmark, Greenland, and some parts of the Mediterranean coast. Happily at the present time it is unknown as an indigenous disease in Great Britain, though about four hundred years ago it prevailed over the whole of Europe, and these islands were not exempt. Statistics prove that it is oftener met with in males than in females, and that the age between 15 and 30 is that most liable to its attacks. It is certainly rare before puberty.

As to the causes of the disease we know but little; for, though it is confined to certain localities, one is at a loss to discover what malarial or other exciting influence exists in common on the coast of Norway, the Mediterranean, and the West Indies. It is undoubtedly sometimes hereditary, though never contagious.

It is to a case of tubercular leprosy that I propose particularly to draw your attention this afternoon.

Mary Anne Edmunds, aged 45, was admitted into Middlesex Hospital on October 5th, 1871. She stated that she was born of English parents in the West Indies, where she remained during the first twenty years of her life. She then resided in England for four years; subsequently she returned to the West Indies for one year, and at the age of 25 she went to live on the West Coast of Africa, and there remained until two years ago, when she again came to England, and has since lived in London. She has one brother and four sisters, all healthy. Her eldest son died in Africa; her other children, four in number, are all strong and well, and she is not aware that any member of her family has been afflicted with a similar disease.

She suffered from what she calls "climate fever" in the West Indies, but otherwise enjoyed good health, until she went to Africa, where the present disease commenced nearly six years ago. She firmly believes that it was produced by artificial means, some malicious person having rubbed her skin with a poisonous herb, and thus injured her for life. Nothing that we can say to the contrary dispels this extraordinary delusion. She describes the first symptoms as having consisted of vomiting and pain in the abdomen, with a sensation of numbness and tingling in the limbs, especially affecting the hands and feet; these were shortly followed by slight swelling of the upper and lower extremities, with some discoloration of the skin, and six months afterwards the face became similarly affected; at the same time she began to lose her sight, "a skin," as she describes it, gradually growing over her eyes.

Her state of health has changed but little during the last twelve months that I have had her under my observation, and may be briefly described as follows. She is a tall, well-formed woman, but emaciated; the hands, feet, face, and mucous membrane of the mouth and throat, are the parts of the body most seriously affected. The skin of the hands is of a darkish-brown colour, and enormously thickened by tubercular swellings, which are scattered irregularly chiefly on the dorsal aspect of the hand and wrist. The fingers are more uniformly enlarged, and measure in circumference round the middle as follows.

	Right Hand.	Left Hand.
Index finger.....	4½ inches.	4 inches.
Middle finger .....	4 "	3½ "
Ring finger .....	4 "	3½ "
Little finger .....	4 "	3 "

The measurements were made about the middle of each finger. The palms of the hands are comparatively free from disease; on one finger there is a large and painful tubercle, which is now increasing in size, and giving evidence that active changes are going on at this spot. She is quite unable to close the hand or even to bend the distal joints of the fingers. Brown patches of discoloration are scattered over the skin of the fore-arm, some of them reaching as high as the shoulder, while here and there a small hard lump can be felt in the skin. There is entire loss of sensibility at the back of the right wrist over a patch of skin rather larger than a crown-piece; elsewhere the sense of touch is nearly perfect, although a sensation of numbness exists. The feet, like the

hands, are diseased, but in a less degree; they are of a darkish-brown colour, patches of the same hue extending up the leg. The face is frightfully disfigured by the irregular thickening and wrinkling of the cutaneous tissues, which is especially marked about the lips, nose, that part of the cheeks just below the eyes and the forehead, so as to present the well-known leonine expression.

There exist the remains of several scabbed sores and scars on the face and hands; a large one is especially noticeable in the centre of the forehead. Rather more than the lower half of each cornea is opaque; but the pupil may be seen by looking obliquely downwards through the upper part, which remains tolerably clear. The patient can perceive light, but is unable to distinguish objects. The tongue is fissured and indented; the mucous membrane of the fauces, soft palate, and epiglottis, is much thickened, and tuberculated; she speaks in a hoarse whisper, and is troubled with a harsh persistent laryngeal cough, showing that the larynx is seriously involved. The skin of the trunk is tolerably healthy; the senses of taste and smell are not much impaired, and the hearing is perfect. The patient complains of general weakness, loss of appetite, and great difficulty of walking.

A few days ago, a little solution of atropine was dropped into her eyes; this enabled her to distinguish objects, so that she could count the fingers of a hand held up a yard from her face, showing that the loss of sight is due only to the opacity of the cornea.

With the exception of the above-mentioned parts of the body—namely, the upper and lower extremities, the face, eyes, and the upper part of the respiratory and alimentary mucous tracts, we are not aware that any other organs are at present especially affected by the disease.

This I take, gentlemen, to be an almost typical case of elephantiasis Græcorum: an individual, born in the West Indies, healthy until she was upwards of 30 years of age, then attacked with leprosy, ushered in with the usual premonitory symptoms, such as general debility, numbness and tingling in the limbs, followed by swelling and general discolorations of the skin, first of the hands and feet, and subsequently of the face; gradual development of morbid growths in the skin of the same regions; general emaciation and loss of power, especially in the lower extremities; blindness, local anæsthesia, and a diseased state of the mucous membrane of the fauces, exactly similar to that of the hands.

If we could carry on in imagination the history of this unfortunate woman, it would probably be from bad to worse; the mischief gradually extending itself down the larynx and trachea, and thus leading to suffocation; or perhaps an accidental inflammation of the lungs or some other important visceral organ may cut short a life of helpless misery.

I have already said that we know but little of the general pathology of this remarkable disease. The chief predisposing cause is, no doubt, an hereditary taint, which, however, is not applicable to the case before us, inasmuch as our patient was born of healthy English parents. We must look, then, to the exciting causes alone, to account for its appearance. Amongst them, those most generally believed in are malarial poison, fish diet, putrid food, and bad general hygiene; but leprosy sometimes occurs without any of these attendant circumstances; all, no doubt, promote this form of elephantiasis, just as they promote many other maladies, but the real origin of the disease remains yet to be discovered. The disappearance of leprosy from England under improved hygiene merely proves that the disease, like the plague, is nursed and fostered by poverty and filth.

Against the hypothesis that it depends on some malarial poison, we have the fact that it is common in some well-drained and otherwise healthy districts, and that the whole course of the malady, its morbid anatomy, with the growths of new and adventitious tissue, ally it much more closely to such diseases as lupus, cancer, and syphilis, than to ague and tropical intermittent fevers, which we know to be of malarial origin.

We may sum up what is known of its general pathology in three short sentences:—1. It is a widespread malady, though confined to certain districts, which differ much from each other in race, climate, and geographical configuration. 2. It is more or less hereditary. 3. It is a disease of young adult life.

With the medical anatomy of leprosy we are pretty well acquainted. There are two points of reference to this part of my subject which I would particularly impress upon you: the first is, that elephantiasis Græcorum is not simply a disease of the skin, but of the whole system; for, although it is classed in our textbooks amongst cutaneous affections, and that shows itself in the superficial tissues of the hands and face, yet in protracted cases almost all the organs of the body may become involved; moreover, the general constitutional disturbances at the outset, and which are never absent during the whole course, point to the fact that it is not simply a local affection. Secondly, the local evi-

dence of the disease is manifested by distinctly *new growths* invading the healthy tissues of the body. If we make a section of the leprosy tubercle in an advanced stage, and examine this under the microscope, we find that the normal tissue of the true skin is replaced by a new cell-growth, which seems to destroy the connective and fatty tissues, though it is not confined to the district of the true skin, but extends deeply into the subcutaneous layer, the epidermis remaining comparatively unaffected. Besides the corium, the perspiratory and sebaceous glands are destroyed, and the growth of hairs arrested; the nerves are often invaded by the cell-growth, and become atrophied; the cells composing the new tissue are for the most part very small, generally about the size of pus-corpuscles.

One rather characteristic feature of the disease, and which a few months ago we had ample opportunity of observing in our patient, is the formation of open sores, which are sometimes due to a degenerative change and ulceration in a leprosy tubercle, or more commonly to the appearance of bullæ, like those of chronic pemphigus, which burst and leave an unhealthy ulcer, and ultimately a whitish scar. When our patient first came under treatment she was suffering severely from these open sores; but now, under the use of tonics and local applications, she is free from this troublesome complication.

With regard to the treatment of leprosy I am afraid there is little to be said, and that little far from satisfactory. I have had no experience of the late Dr. Beauperthuy's method, said to have been successful in the West Indies, and therefore I have no right to express an opinion on the subject; nevertheless, the nature of the disease must check a too sanguine expectation that any treatment of individual cases is likely to be permanently successful. Improved general hygiene, with moral checks upon intermarriages amongst those affected, is the only plan that will produce permanent and useful results.

## ABSTRACT OF CLINICAL LECTURES ON OPHTHALMOLOGY,

*Delivered at St. Thomas's Hospital, London.*

By R. LIEBREICH, M.D.,

Ophthalmic Surgeon and Lecturer to the Hospital.

### LECTURE IV.—*Atrophy of the Optic Disc.*

GENTLEMEN,—The atrophy of the optic disc may be the consequence of a variety of affections of the retina, of the optic nerve, of the brain, of the spinal cord; and I need scarcely mention how important it is to recognise the nature and the course of the disease which gave rise to the atrophy of the papilla.

To obtain a general survey of the different forms of atrophy, let us look at the cases depicted in my *Atlas*.

These drawings appear so different, that you can scarcely designate the general characters of the atrophy otherwise than vaguely as a diminution of redness in the colour of the papilla, with a smaller diameter of the vessels. You may perhaps be astonished not to hear me speak of a diminished diameter of the papilla itself. This supposed symptom is, indeed, indicated in many handbooks on ophthalmology, but I have very often taken quite exact measures of the diameter of the optic disc in the living eye, as well as in anatomical preparations, and never could find any diminution, in cases even of the most absolute atrophy of the optic nerve. There is, in fact, a loss of substance produced by the disappearance of the nerve-fibres. The mechanical changes caused by this loss are to be found in a plane which passes through the axis of the optic nerve, and you will easily observe this circumstance by the flat, atrophic excavation seen either with the ophthalmoscope or under the microscope in a longitudinal section of the nerve. The plane perpendicular to the axis of the optic nerve, which, with an ophthalmoscope, we distinguish as the optic disc, remains in form and size unchanged even after a complete atrophy of the nerve-fibres.

If the border of the papilla—that is the, hole within the choroid (choroid limit) and the edge formed by the transition of the sclerotic and the nerve-sheath (sclerotic limit)—remain in the same place after the disappearance of the nervous substance surrounded by these limits, it is, *a priori*, necessary to suppose that some new substance vicariously fills up the empty space. This is, indeed, the case, and it is the nature of this new substance which determines chiefly the difference in the aspect of the papilla.

In all cases in which the atrophy of the nerve-fibres is produced without any preceding disturbances in the retina or in the papilla, it is the vitreous body which fills up the excavation. This body, being much more transparent than the nervous substance of the papilla, allows us to distinguish, with much more clearness than in the normal eye, the white

network of the lamina cribrosa, which now appears not only in the centre, but throughout the whole extent of the optic disc. For the same reason, the sclerotic limit and the border of the choroid appear too sharply delineated. If, on the contrary, the atrophy of the optic disc be preceded by an inflammatory process of the retina and the papilla, or the latter alone, the disappearing nerve-fibres are replaced by substance of new formation. This substance is more opaque than the nerve-fibres, and consequently covers the lamina cribrosa, which disappears more or less completely, whilst the contours of the papilla, also more or less covered, appear weaker, undecided, and irregular.

These conditions will furnish you with the most important points on which you will have to rely for your diagnosis, especially if you also consider the state of the blood-vessels. To obtain these observations it is necessary to examine the direct image. In order to be able to examine the direct image without artificial dilatation of the pupil, it is necessary to use a mirror with a sufficiently small and carefully worked hole in the centre. If the hole be nearly as large as the pupil of the patient, it is impossible to throw light enough into his eye. If the margin be irregular, containing little scratches, or if it form a channel instead of a sharp ring, the reflex of light proceeding from this border puzzles the observer by producing entoptic phenomena in his own eye.

A very small part of the mirror only throws light into the pupil—namely, that which immediately surrounds the hole. It is therefore quite useless to use very large mirrors, which are tiresome to the patient, without giving a stronger light to the part of the fundus under observation.

Since I gave these explanations, the diminution of the mirror and its central hole has often been made too great. If the mirror is too small, it cannot well be put against the supraorbital margin, and insufficiently protects the observer against the flame. Too small a hole has two great inconveniences; at first it diminishes the intensity of the light, allowing only too small a pencil of light to pass from the observed to the observer; secondly, it acts as a stenopaic apparatus, and deprives us of our judgment on the refraction of the patient by suppressing the circles of dispersion.

I therefore propose to make the hole not smaller than two millimètres, and the mirror not smaller than three centimètres, and to use in preference a thin silvered glass mirror, the centre of which is not perforated, but only deprived of the silver covering. The focus of the mirror may be of eight or ten inches.

## ON THE PATHOLOGY AND TREATMENT OF INTESTINAL WOUNDS.\*

By T. D. GRIFFITHS, M.B.Lond., Swansea.

THERE is an interesting case of wounded intestine at present under the care of Mr. Andrew Davies at this hospital, of which the following is a brief history.

L. K., a Belgian, aged about 30, was stabbed in the belly on the evening of the 17th of June last. I and Mr. Jabez Thomas of this town were in attendance on him shortly after the occurrence. The patient was found propped up in a chair, violently sick, with his face ghastly pale, and bedewed with perspiration. He was immediately placed on his back on a table in the room, the head being supported on pillows, and the knees flexed and drawn up, when the small intestines were observed to protrude about two feet through a vertical aperture two inches in length, half way between the umbilicus and the pubes, and a little to the left of the middle line. The protruding gut was distended, greatly congested (a large portion of the mesentery corresponding to the protruding intestine being partially strangulated), and wounded in two places, in the transverse direction. The wounds were in the same transverse line, and evidently made by one thrust of a sharp-pointed knife, transfixing the gut; the larger wound admitted the end of my index finger as far as the root of the nail; and the smaller, the point of an ordinary grooved director. The wounds in the intestine presented a peculiar appearance. They resembled fungous excrescences, circular in outline, and of darker colour than the surrounding serous membrane. The lips of the wounds were everted, and the mucous membrane protruded, giving rise to the fungous appearance, and closing the apertures in the intestinal wall. On introducing the end of my index finger into the larger opening, and afterwards the end of the little finger, with the object of reducing the distension, which appeared to me to be caused by flatus, the walls of the intestine, to my surprise, remained in the same distended state, the reverse of what happens in the distended intestines of a dead subject when punctured. After stitching the wounds in the

intestine, it was found necessary to extend the opening in the abdominal wall from half to two-thirds of an inch, to enable the protruding mass to be returned; some difficulty was afterwards experienced in closing it (the intestines seemed to be more than the peritoneal cavity could contain), which was done by three hare-lip pins and one suture; and, to lessen the tension, two or three long strips of plaster were passed over the hip-bones and round the trunk. After taking thirty minims of laudanum, the patient was removed to the hospital.

Mr. Lloyd, the house-surgeon, with Mr. A. Davies's permission, has kindly furnished me with the following notes of the case since admission to the hospital. "Two ounces of brandy were given to the patient on the night of admission; one grain of opium every three hours for the first three days; one grain every four hours from the third to the seventh day; and one grain every night from the tenth day (June 27th) to the present date (July 5th). The patient was put on barley-water and ice for the first four days; on barley-water, ice, milk (from 1½ to 2 pints), and one egg daily from the 4th to the 17th; and, on the 17th day, rice and minced meat were ordered for the first time. The bowels acted after an enema on the tenth day after admission; also on the tenth and twelfth days; and of their own accord on the fourteenth day. The patient suffered from bilious vomiting for the first five days. With the exception of this sickness, he has had no unfavourable symptom. The wound in the abdomen is nearly healed over, and the patient feels comfortable, but is still confined to his bed."

This case suggests three special points, to which I desire to call your attention, and from which some conclusions as regards treatment may be drawn.

1. *The Appearance and Character of the Wounds in the Intestine.*—The wounds presented the appearance of fungous excrescences, produced by the protrusion of the fibrous and mucous layers, thus closing the openings and preventing the escape of the contents of the intestinal canal. On thinking over the subject, it occurred to me that the division of the longitudinal muscular layer, which is exterior to that of the circular muscular fibres, might probably account for this peculiar appearance. To satisfy myself on the subject, I made some experiments on a spaniel dog on July 3rd, being kindly assisted by Dr. John Williams. The animal having been put under the influence of chloroform, the peritoneal cavity was opened, the omentum turned aside, and some coils of the small intestines were drawn out. One cut was made by thrusting a sharp-pointed dissecting knife into the intestinal canal, dividing the coats in a transverse direction, to the extent of three-eighths of an inch; immediately the serous membrane began to retract, and in a few seconds the wound assumed the appearance, as remarked by Dr. Williams, of a stoma; the eversion and the protrusion of the fibrous and mucous layers kept the opening closed, and prevented any escape of the contents. The semi-distended condition of the gut was the same before and after the opening was made. The bowel was next opened half an inch in a longitudinal direction; the edges of the wound in this case remained in apposition, or, rather, were inclined to invert; one lip seemed to turn in more than the other. The latter opening was stitched in the way recommended by Mr. Erichsen, by passing the needle through the serous coat some distance from the edge of the wound, and out through the same near the edge, and afterwards passing the needle under a similar portion of the serous membrane on the opposite side of the wound, so as to bring the two serous surfaces into contact. The transverse opening was not stitched. The gut was returned, and the abdominal wall closed by hare-lip pins. The animal having recovered from the influence of chloroform, was given thirty minims of laudanum; the dose was repeated twice during the day; no anodyne was administered the next day. The dog had been well fed up to the time of the experiment, but only water was allowed afterwards. On the morning of July 5th, the dog was again put under the influence of chloroform, and the peritoneal cavity was opened on the right of the middle line, corresponding to the opening made on the opposite side on the 3rd instant. A coil of the small intestine was opened half an inch in a diagonal line; by this section, the longitudinal and the transverse muscular fibres were divided; the whole thickness of the edges retracted equally—that is, without any eversion or inversion; and the wound gaped, allowing the fluid contents to escape. The experiment over, thirty minims of Scheele's prussic acid were poured down the throat, and breathing ceased in two minutes and a half. A *post mortem* examination was made forty-eight hours after the first operation, to ascertain the condition of the wounds. The longitudinal opening, which had been stitched, was covered with a layer of semitransparent lymph; but over the stitches it was more abundant, and of softer consistence, in appearance resembling thick pus. The transverse wound appeared, upon the whole, healthier

\* The substance of a paper read before the South Wales and Monmouthshire Branch of the British Medical Association, at Swansea, July 5th, 1871.

† The patient has been reported as "convalescent" since the above notes were given.—T. D. G.

than the other; it was also covered with a semitransparent layer of lymph, which extended over the parts in the immediate neighbourhood; there was no evidence of any of the contents of the intestinal canal having escaped through it. On opening the bowel, it was found to contain a quantity of soft substance where the transverse opening had been made, none of which had found its way between the edges of the wound. It is evident from the above observations, that the appearance and character of the wounds depend upon the direction in which they are made. When transverse, the longitudinal muscular fibres, being divided, retract, evert the edges, and pull upon the fibrous and mucous layers, and thus cause the fungous appearance already described, and fill the opening, and prevent any of the contents of the intestinal canal from passing through. When the wound is longitudinal—that is, parallel to the longitudinal muscular fibres—the transverse muscular fibres are divided, and, by their retraction, keep the edges in apposition, being partly inverted. And when the longitudinal and transverse muscular fibres are both divided, as they must be when the wound is in a diagonal direction, the edges retract and the wound gapes, allowing a free exit to the intestinal contents.

These remarks are only applicable to wounds of the intestines not exceeding half or three quarters of an inch in length.

2. *Distension of the Wounded Intestine.*—It is evident from the history of L. K.'s case, and that of the dog, that, although only partly filled with food undergoing digestion, the intestinal canal may retain a distended appearance before and after it is opened. The peristaltic action observed in the intestines consists of an alternate dilatation and contraction, as well as elongation and shortening of the successive portions of their coat. The dilatation and shortening are produced by the longitudinal, and the contraction and elongation by the circular muscular fibres; the two muscles are antagonistic in their action, and hence the explanation of the dilated or partially distended appearance after the intestinal canal is opened in the living subject. The partial strangulation of the protruding gut and its mesentery may possibly account for the excessive distension observed in L. K.'s case.

3. *The Mode of Stitching the Wounds of the Intestines.*—The method recommended by Mr. Erichsen, and which was adopted in the dog's case, may be objected to on the ground that it materially diminishes the calibre of the intestinal canal, in case of a longitudinal wound, by the folding in of the coat in bringing the serous surfaces into contact; and in case of a transverse wound, the gut is bent by the folding in of the wall on one side, and a transverse projecting ridge is formed in the interior of the knuckle thus formed; all these conditions would obviously render the patient liable to constipation, colic, and intestinal obstruction. The plan that commends itself most to my mind is the interrupted suture. The needle should be passed down through the whole thickness of the intestinal coat, about one-eighth of an inch from the edge on one side of the wound and up on the opposite side. The silk should be tied tolerably tight, so that the soft part included in it may ulcerate more readily, to allow the stitch to drop into the intestinal canal. By this method the wound is closed, the edges are kept in apposition without interfering with the calibre of the gut, and the sutures are removed in the course of a few days.

The continuous suture, and the ligature passed round so as to include the edges of the wound, are methods which, for obvious reasons, need only be mentioned to be condemned.

From the foregoing arguments it may be fairly concluded, that longitudinal and transverse wounds of the intestines not exceeding half or two-thirds of an inch in length need not be stitched, their edges being kept in apposition by the action of the muscular coats—nay, more, that stitching in these cases is a meddlesome interference with nature, which is capable of repairing the breach without the surgeon's aid; and that the only wound which requires stitching is that which is gaping, and is diagonal in direction to the transverse and longitudinal muscular fibres.

## THE TRAINING, QUALIFICATIONS, AND DUTIES, OF NUISANCE-INSPECTORS.\*

By DAVID DAVIES, M.R.C.S.,

Inspector of Health for Bristol.

No medical officer of health can be ubiquitous; nor can he by himself, however small the district under his superintendence, be thoroughly and always acquainted with the condition of every place in his district—a knowledge which is absolutely necessary for the due performance of the duties of his office. To be always possessed of this knowledge, he must

be assisted by a number of non-medical assistants, who are commonly called "nuisance-inspectors", with whom he should be in personal communication at least once daily. As the success of every health-officer must depend to a considerable extent on the character of his assistants, I will endeavour to describe in brief outline what that character should be, as it appears to me from personal experience.

A nuisance-inspector should be free from all organic disease. He should have passed through small-pox, or have been well vaccinated and also revaccinated, before he commences his duties. He ought also to have passed through scarlet fever, measles, and maculated typhus; and it would be an additional recommendation if he has suffered from a well-marked attack of enteric fever, as I find that one attack of even this disease is to a considerable extent protective from future attacks. He should be largely endued with good health and the natural courage arising from good digestive powers; and, above all, he must possess that "something", indescribable in language, and upon the possession of which we as Englishmen pride ourselves, which impels us under adverse circumstances to do our duty irrespectively of the probable result.

This may be considered a high standard for the mere raw material of a nuisance-inspector, and possibly too high to be found every day or in every place; but I can venture to state that the watch committees of our large towns have always within their knowledge many such characters, whom, however, they are loth and tardy to recommend for promotion, for the simple reason that they do not wish to lose their services as thief-catchers. I may here add that the only literary qualifications requisite, are ability to speak the vernacular language of the district with fluency, and to enter on their journals in intelligible language the most prominent points of their daily occupation.

Such a man having been found, and appointed to office, his special training commences. He must not think that the burden of his duties consists in making himself disagreeable to everybody; in racing after every stray pig or half-starved donkey that may have found (very inappropriately, I confess) lodging in our crowded cities; or that he is to waste his time in listening to the querulous statements of rich old maiden ladies who think they perceived "a smell", as on their way to church on Sunday they passed a street inhabited by poor people, who may have been at the time cooking their potatoes and herrings for a late breakfast. He must not be the handle by which one neighbour can revenge himself on another on account of some petty quarrel between the wives or the children. He must, if taken from the police-force, once and for ever forget that he was a thief-catcher; he must shut his eyes to all that in his former vocation would have roused his inmost spirit, and by so doing he will acquire the utmost confidence of the people among whom his duties chiefly lie; he must learn to believe that the sole object of his duties is to aid in prolonging the lives of the people, regardless of how those lives may be spent. I feel strongly that the duties of a police-officer are totally incompatible with those of a nuisance-inspector. I could substantiate my assertion by facts, but time forbids.

If taken from the police on the recommendation of the Watch Committee, the nuisance-inspector will have learned not to believe all he hears, and at the same time to treat with civility every person making a statement to him. But he must go further than this; as he is no longer a policeman, he should try to prove himself a friend to every one in his district. He should have a great deal of human nature in him; he should acquire the confidence and respect of the clergyman of the parish and of the dissenting ministers; he should be on terms of intimate friendship with the Scripture-reader and the city missionary (most valuable and productive sources of information); he ought to be acquainted with the relieving officers of his district; and, when opportunity offers, he should endeavour to acquire the confidence and good will of members of our own profession practising in his district. They have it in their power to aid him beyond all others when they have the good will to do so. He should make himself acquainted with the owners of all the small tenements in his district, and with their character. His eye should watch every doctor's carriage, every closed shutter, every funeral procession. In friendly conversation with the people, he should find out all that is going on; and in his daily interview with the medical officer, he should report all he has learned and take his advice on it.

He will find on his appointment that he is deficient in many points of special knowledge. He should acquire at least a smattering of natural philosophy. He should thoroughly understand the construction of a good eject or gas-trap; the management of a heat disinfecting apparatus; the nature and application of disinfectants. He ought also (as I think) to be acquainted with the rough outlines and the mode of propagation of the principal zymotics. I am afraid I am treading on tender ground here; but I cannot call any man a nuisance-inspector without this knowledge, as the chief and most dangerous nuisances are the zymotics. This knowledge is easily communicated where there is

\* Read before the Public Medicine Section at the Annual Meeting of the British Medical Association in Plymouth, August, 1871.

a medical officer of health. To illustrate the necessity of this, I may say that I have often, when cases of fever have prevailed in a quarter not accessible to me, or deaths from it have been ambiguously reported in old-world nosology, ascertained through the inspectors, to my own satisfaction, what the disease was—whether typhus or enteric fever; diphtheria or scarlet fever; small-pox, erysipelas, or measles; Asiatic cholera or diarrhoea; and upon such conclusions I have taken my measures. It would certainly interest the profession to learn how these trained detectives can tell the name of the culprit by the style of the mischief done, although they have never seen the patient. For instance, the duration of the disease, with the presence or absence of diarrhoea, with other points ascertained in quiet gossip with a neighbour, will enable them to distinguish between maculated typhus and enteric fever. The character of the locality, the absence of infection, the age of the patient, the duration of disease, with minor points easily ascertained, will often point to “tubercular meningitis” and not to “typhus”, which may appear as the cause of death on the return made to the Registrar-General. My measures have always been taken according to my own conviction on the reports of the inspectors when the case was not accessible to my own inspection, or reported to me by a member of the medical profession.

The inspectors should be well paid, so as to be able to live generously, and so become less liable to be affected by any of their unpleasant and dangerous duties. They should not be expected to do any menial work, but each should be allowed to have at his command two labourers for the immediate removal of minor nuisances not requiring constructive work, for whitewashing courts and alleys and for the application of disinfectants.

The district under the charge of each inspector should not be too extensive. The extent might vary according to the character of the locality. Where the population is poor and the district contains many courts and allies, a population of 20,000 would give ample work to an able man; for fashionable localities, with well-to-do residents, it might be extended indefinitely.

The nuisance-inspector should be thoroughly acquainted with all the sewers and drains, so as to be able to give advice for remedying any defect in the connecting drains. He should walk through the whole of his district daily; and twice a week at least, either through himself or the men at his command, inspect every privy in the courts and alleys easily accessible. These privies should be disinfected each time they are inspected.

Although not expected to do any menial work in a general way, he must be prepared, in case of a sudden outbreak of Asiatic cholera, to take disinfectants in his own hands; in the absence of his men, to visit the affected premises; and, under the guidance of the medical officer, not to leave them until every particle of the choleraic poison has been destroyed.

To sum up his duties, they are as follows:—To see that there is no escape of sewer-gas in any part of his district; to see that the surface of the ground surrounding houses is hard and impermeable to water; to see that there is no unnecessary accumulation of dirt in any place within his district; to find out and report every case of infectious disease to the medical officer; to take his instructions on every case and see them carried out; to give instructions and to superintend the men at his command for doing menial work; to enter on his journal daily a summary of every day's work.

I have not dwelt on the large amount of unnecessary trouble given to the nuisance-inspectors by timid old ladies and sometimes timid old gentlemen who have in their walks passed a garden with some rotten cabbages in it, or have seen a dead cat or dog where such should not have been found, or have smelt a little ammonia from their neighbour's stable. These complaints being of an æsthetic rather than of a sanitary import, I have paid but little attention to them.

There are also other duties imposed on nuisance-inspectors by their employers—such as finding out the addresses of parties to be summoned and serving notices on them, inspecting the watering of the streets and the scavenging, checking the water used for street-watering, etc.; but with these duties I have had nothing to do. Such duties should not be too numerous; and, in my opinion, it would be better to employ a special officer for some of these, so as to leave the nuisance-inspectors free to perform only sanitary work.

I have thus attempted to sketch out in faint outline what a nuisance-inspector ought to be. With men more or less like the pattern I have drawn, it has been my good fortune to work for six years. Without them, I could have done but little. They are my *antennæ*, by whom I can probe the most hidden arcana of a large city. Many of the measures recommended by and attributed to me were originally suggested by them.

In concluding, I may say that on one or two occasions, under the panic of a threatening epidemic, other bodies and private associations

have sent out amateur inspectors. These, with the zeal of new recruits, have reported imaginary nuisances by hundreds, and have so done much more harm than good by calling away the trained men to confute their reports. There have been some exceptions to this; but, on the whole, amateur nuisance-inspecting is like some other amateur work—very indifferent in character, and often injurious. The duties of a nuisance-inspector are to an able man simple enough, but they must be learned.

Nuisance-inspectors are indispensable assistants to health-officers—qualified members of our profession—but still only assistants. Unless guided, supported, and assisted, by the experience and influence of medical officers who can command the respect of the public, they will fall easy victims to the thousand and one theories of self-made sanitarians who abound among the unoccupied and affluent residents of our large cities, who have been the victims and supporters of all the mischief-producing theories which, like a blight, have blown over scientific medicine.

In conclusion, let me tender a sincere apology for the meagre and imperfect character of this paper, which was written only at the earnest, and, I may say, importunate, entreaty of our respected chairman, who is one of the most devoted votaries of Hygieia.

## ANOMALOUS SYMPTOMS IN A CASE OF MORPHIA-POISONING.

By JOHN SPENCER FERRIS, M.B.Lond., etc., Uxbridge.

DR. GUY, in his book on *Forensic Medicine*, after stating that the symptoms of morphia-poisoning are those of opium and its preparations, relates two or three anomalous cases in which tetanic spasms were prominent symptoms, and throws out a suggestion that the three grains of acetate of morphia that Palmer gave Cook were the real cause of the latter's death, and not strychnia, as was generally supposed. On this ground, and on the similarity of the symptoms to those of strychnia-poisoning, I think the following case important.

Sarah V., aged 60, cook, who was just recovering from a severe attack of bronchitis, took at 2 P.M., March 19th, twenty-five drops of a solution of muriate of morphia for a bad cough and diarrhoea. She was then left alone; but at 4 P.M. she rang the bell. The nurse went up and found her lying on her bed bathed in perspiration; the face was swollen, and the eyeballs protruding; both sides of her mouth were twitching; the arms were bent, and moved backwards and forwards convulsively. In a moment the movements ceased, and she complained of great pain in the chest, and could not take a long breath. She said she could not see anybody or anything. After a time, the convulsive movements in the arms and face returned. She had great pain in the back and partial opisthotonos, with delirium, and fainted several times, so that she was thought to be dead. A large quantity of warm water was given her, and she was very sick at 5.30 P.M. I saw her at 6 P.M. I found her complaining of great pain in the chest, principally in the middle of the sternum; the breathing was short and quick, and she sighed often; she also had pain in the bowels. Her legs were twitched up, and she begged that they might be held as she could not keep them quiet, and said it felt as if there were worms in them. She had also pain and twittings all down her spine. The pupils were very much contracted, not being so large as a pin's head, and she saw red and black spots floating before the eyes. The pulse was about 60. She had no disposition to sleep; the cough had entirely ceased since taking the morphia, though incessant before. All the pains and convulsions then left her, and she was quite easy for two or three minutes, when they returned again; the nurse told me that, ever since she was taken, there had been distinct intervals between the paroxysms. The patient afterwards told me that she first felt the effects about half-an-hour after taking the morphia; that the first symptom was violent pain in the chest and inability to take a deep breath, and then pain in the bowels; and that she never had any disposition to sleep, and she could always open and shut her mouth freely, and therefore had nothing like locked jaw. I gave her sal volatile, brandy and water, and strong tea, which she swallowed without difficulty. Warmth was also applied to the bowels and chest. The convulsive movements and pains gradually left her; and when I quitted her house at 9 P.M., she was only complaining of slight sickness and pain in the head. She could not see distinctly, though the pupils were still much more contracted than usual. The twenty-five drops of morphia were dropped out of a four-ounce bottle, labelled “Solution of Muriate of Morphia, ten to sixty drops per dose,” obtained from a chemist in Reading, so that I cannot exactly tell the strength, more especially as these were almost the last drops in the bottle, and very probably there was some undissolved alkaloid in them. How is it a chemist, now that the Phar-

macy Act has come into operation, dares to sell to an unprofessional person four ounces of morphia solution? I may say that fourteen years ago, when she broke her leg, she had tetanus. On March 20th, at 10 A.M., she had been easy all the night and had no twitches, but slept only about an hour. Pulse 60. The pupils were still contracted. She said that her legs and arms felt as if they were alive, and as if they were going to jump up. She complained of a stiff neck, and of being "sore all over". She had passed but a very little urine with great difficulty. The tongue was foul. The bowels had not been open. There was no cough. On the 21st, she was much better, and had none of the feelings of which she complained on the previous day in her limbs. The cough had returned. The pupils were normally dilated, and her eyesight was as good as ever; in fact, she seemed to have no relic of the morphia-poisoning.

## CLINICAL MEMORANDA.

### MR. ELLIS'S MODE OF VACCINATING.\*

I HAVE had favourable experience of the plan of vaccination advocated by Mr. Robert Ellis, of Chelsea, in January 1871. It seems to me, indeed, that its value in revaccinations can scarcely be overrated, as it proves more certain than any other plan. Thirteen cases in which I have adopted it have all "taken" decidedly, although eleven of them had, during the previous few weeks, been operated on repeatedly by myself or others, both with lymph from ivory points, and with fresh lymph direct from arm to arm, without any effect. I would suggest it should be recognised and established generally in the profession, as the most eligible mode of revaccinating; for although too troublesome (requiring two interviews with the patient) for common use, it offers under certain circumstances—as in persons about to go abroad, or compelled to submit to exposure to small-pox infection—advantages, in its certainty of effect, apparently unattainable by other methods. The very unsatisfactory observation "not taken", and the equally unsatisfactory inference of "not susceptible", often made after other modes of operation, may hereby be rendered almost obsolete.

Mr. Ellis's plan consists simply of applying, with a very small brush, to some spots on the arm, enough acetum cantharidis to cause in each place a blister about the size of a pea to have risen by the next day. This vesicle is to be punctured (at top), and the fluid having been pressed out, an armed ivory vaccine point is to be inserted, and left there for a few minutes. As large and energetic pocks result, two (or at most three) will suffice. It is essential to success to first procure a good little blister; therefore, to ensure the action of the acetum cantharidis, it is well to previously free the skin from its natural greasiness by a thorough washing. Some ether on a dossil of rag is very effectual to this end.

GEORGE F. HODGSON, Brighton.

### VARIOLA CONFLUENS AFTER RECENT REVACCINATION.

I HAVE just attended the following case of variola confluenta, which proved fatal on the morning of the fifth day of the eruption, in a young man who had been very recently revaccinated.

George B., aged 22, A.B., of H.M. ship *Narcissus*, was seen by me first on Sunday afternoon (29th ult.) at Cawsand; he was staying with his relatives there, having been granted leave of absence for a few days. I found him very feverish, with severe lumbar pains, sickness and extreme prostration. On inquiry, I learnt that he began to feel ill only on the previous Friday evening, and, attributing his symptoms to a feverish cold, he did not seek advice before. He was immediately ordered to bed, and placed under treatment. The following day, the symptoms continued unabated, although he had had some sleep during the night. On a careful examination of his skin, no efflorescence or eruption was detected, except on his left arm, where I saw the remains of a bull-sized recent vaccine pustule, with falling scabs. The next morning (31st ult.) his body was covered with a deep purple erythematous rash, in crescentic patches, very dense on the lower extremities; this in the course of the day was covered with imperfectly developed pustules, all running into each other, except a few on the wrists and the back of the hands. The pocks on the face were small, thick, and very confluent, the skin being very livid, but not much swollen; on the day previous to my patient's death it was of a very dark hue.

The local typhoid symptoms, attendant on this condition, rapidly increased; deglutition becoming very difficult, from the fauces, velum, etc., being extensively affected, and he sank early on Saturday, the 4th instant. There were no hemorrhages or diarrhoea.

It was ascertained that George B., had been revaccinated, with some of his shipmates, on Oct. 20th, and, as stated above, one large pustule was the result.

EDWIN J. WORTH, M.R.C.S. Eng., etc.,  
West Anderton, Millbrook.

### CASE OF MULTIPLE MALIGNANT TUMOURS.

I BRIEFLY record an unusual case of multiple malignant tumours. The patient was a gentleman, aged 60, who had led an active and temperate life, and who had retired from business to the country four years ago. With the exception of occasional attacks of dyspepsia, he had enjoyed good health till the close of last year. He then began to suffer from loss of appetite and nausea, with a thickly furred tongue, and great pain over the region of the sternum; and he complained of what he termed "blind boils" on the back. On examination, I found a subcutaneous tumour, about the size of a hazel-nut, presenting all the character of scirrhus, below the second rib near its junction with the sternum. On the back were several dense well-defined cutaneous tumours, in different stages of development, and varying in size from a threepenny-piece to a half-crown. These were of a bluish colour, due to the presence of numerous minute veins converging towards the centre of the tumours. On the largest of them a crop of vesicles appeared, which gradually enlarged and coalesced; slight oozing of blood occurred, and ultimately the tumour greatly resembled a large ripe mulberry. On the forehead, also, was a conical tumour about half an inch in height. The growth of these tumours was slow; but pain, which had been very great from the beginning, became excruciating about the month of May. The constitutional symptoms also increased in severity about this time, and Mr. Bickersteth of Liverpool visited the patient with me. On passing the hand over the skin, a great number of small tumours could now be felt, which, however, were confined to the trunk, none appearing on the extremities. Death, from sheer exhaustion, took place in the beginning of August.

Treatment was, of course, chiefly palliative, by the local application of extract of belladonna, and various other anodynes, and by the hypodermic injection of acetate of morphia—at first a quarter of a grain, gradually increased to one grain or more twice daily. If the effect of this happened to pass off too soon, the patient's sufferings were very great. Mechanical appliances were also required to protect the tumours from friction, even of the patient's night-dress. A *post mortem* examination was not obtained, but there were no symptoms indicative of the development of tumours in the internal organs.

GEORGE HILL, M.D. Edin.

The Elms, Hooton, Chester, November 1st, 1871.

## THERAPEUTIC MEMORANDA.

### ABDOMINAL PUNCTURE IN TYMPANITES.

IN the latest issue of the JOURNAL, I find that, besides myself, there are several claimants for priority in the practice of paracentesis of the intestine in tympany. Mr. Lawson Tait of Birmingham thinks it belongs to himself rather than to Dr. Davey or Mr. Teale. On reference to my communication of the same date, it will be found to belong to neither. The quotation mentioned by Dr. Littleton in the same issue, from the lecture of the late Mr. Teale, given before the Provincial Medical and Surgical Association in 1845, shows clearly that we are all so far late in the field that priority of performance cannot be claimed by any of us. But perhaps some of us may lay claim to an advance onward from the single operation, to press and employ it as not only a desirable, but a judicious operation. I cannot find that Mr. Teale did more than mention the practice favourably; certainly from that time down to the reading of the paper in March 1868, has the plan been received by the profession as a legitimate operation. In the remarks in the paper just mentioned, I did not much more than state the cases and the results; but before this, in my classes, I had, as occasions occurred, laid down the advantages of the operation; and at one of the Association district meetings, had narrated the cases and recommended paracentesis. But, in point, Mr. Thomas Smith (see *Transactions of the Clinical Society for 1869*), in describing a case where the treatment was adopted, after alluding to my cases, enlarges upon the question, and, without insisting strongly upon the operation, believes that one day it will be of more extended application. Dr. Allbutt's (of Leeds) case was brought out in the *Practitioner* the following month. Then Mr. Wathen, in the paper which has brought forth such interesting correspondence, from totally independent sources, urges its value and instances five more cases.

\* Note read at a meeting of the West Sussex District, held at Worthing.

I am not in possession of the dates to show when the Paris paper was read; but it was somewhere about the time of Mr. Wathen's paper. As twenty cases were quoted, it is clear that Mr. Wathen's four out of five are to be added, as also is that described in the last number by Mr. G. D. Brown of Ealing.

But what is the practical inference to be gained from the appearance of so many independent claimants? Is it not that each one is a separate testimony in favour of a plan which, to say the least, removes one of the most distressing accompaniments of abdominal diseases, thus rendering the later moments of life endurable, and probably, as now many instances show, removing a source of much danger which the increasing pressure of the gas produces.

At present, we can say that, in cases of extreme tympany after failure of other remedies, it is highly desirable to tap the intestines. But, perhaps, when we know more of the operation, we shall find the risk of extravasation less than supposed, and then we may say that, in such cases, the operation is not only highly desirable, but necessary.

J. BRAXTON HICKS, M.D. Lond., F.R.S.

9, St. Thomas Street, S.E.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

#### ST. THOMAS'S HOSPITAL.

##### CLINICAL REPORT OF CASES UNDER THE CARE OF DR. MURCHISON.

In the course of a visit to the wards with Dr. Murchison on October 30th, we noted the following points of interest in connection with cases under his care.

*General Gout: Unsuccessful Treatment by Veratrum Viride.*—The subject of the affection was a beer-drinking carman, 53 years of age, who had frequently suffered from the disease before. When admitted for the present attack, the hand was chiefly affected. He was ordered veratrum viride, with alkali, under which treatment the symptoms became aggravated. Colchicum in an alkaline mixture was then prescribed, and after the first dose the patient began and has continued to improve. His diet has been, during the treatment, beef-tea and milk.

*Obstinate Ascites treated successfully by Elaterium.*—The patient, a careworn but temperate man, had been admitted with all the symptoms of portal obstruction, the cause of which appeared to be somewhat obscure. It was uncertain whether the ascites was due to cirrhosis of the liver or to malignant disease, but it was most probably the latter. From the large amount of fluid which was present in the abdomen, it was found impossible to make out accurately the size of the liver; but, so far as the examination went, this organ appeared to be enlarged, and this enlargement, as well as the tenderness over this region which had been present from the day of admission, was on the increase. He was treated, in the first place, with a pill containing squill, digitalis, and blue pill, under which the ascites increased. He was then ordered iron and digitalis, and afterwards copaiba for a week, but with no better result. Elaterium was prescribed on two occasions during the following week, the copaiba being continued; and the result was that the circumference of the abdomen at once diminished from thirty-six to thirty-three inches, and his breathing was greatly relieved. The patient had not been ordered the purgative previously, as he had at first been suffering from diarrhoea; and Dr. Murchison remarked that the elaterium could not safely be repeated frequently, because of the weakening effect on the patient. He would now return to the iron and digitalis, and would repeat the elaterium occasionally, if the ascites increased.

*Syphilitic Right Hemiplegia, with Aphasia and Agraphia, followed by Paraplegia.*—The patient, a painter, 29 years of age, had been seized with right hemiplegia and aphasia six years ago. The power in the leg began to return before that of the arm, as is generally the case in hemiplegia. The use of the lower limb had, four months after the attack, so far recovered as to enable him to return to his employment, but the arm had, to a considerably less extent, regained its power, and was still wasted. His speech remained little changed for the better. Early in June, while at work, he suddenly lost the use and feeling of his legs, and fell down. With the paraplegia he had retention of urine—a common occurrence in this affection—but this symptom lasted only for a few days. He was now considerably improved, but more so in the left than the right leg. Dr. Murchison pointed out that the patient presented not only an example of aphasia, the loss of the power of expressing his ideas and words by articulate language, but also

agraphia, in so far as in writing he omitted verbs and substituted pronouns in their place. There was no reason to suspect embolism, and no cardiac disease was present; but the patient had suffered from syphilis some years before. From the character and history of the attack, Dr. Murchison looked upon the case as syphilitic, and accordingly had prescribed iodide of potassium, which the man was taking with benefit to the extent of a drachm daily, in combination with tincture of ergot.

*Incurable Disease of Knee-joint: Phthisis: Question of Operation.*—Physicians are frequently consulted by surgeons in cases of disease which require operative interference, but in which the patient presents symptoms of pulmonary consumption. It becomes often a matter of difficulty to decide whether the benefit likely to ensue from removal of the surgical disease, which is affecting the health of the patient, will in any degree outweigh the risk of increased pulmonary mischief. Such a case was brought under Dr. Murchison's notice by a surgical colleague, and the patient was now in the ward. The patient was the subject of painful swelling of the knee, without sinuses. He had a history of rather copious hæmoptysis, and presented a decidedly phthisical aspect. Moreover, there was dulness on percussion, with moist sounds over the apex of the left lung; and he perspired freely at night. Although the pulse was slow and the temperature normal, at least during the day, Dr. Murchison still considered that, so long as the active mischief was going on in the left lung, it would not be expedient to operate for the disease of the knee-joint. A small blister, two by three inches, was accordingly ordered to be applied under the left clavicle; and cod-liver oil was prescribed in addition.

*Acute Rheumatism treated successfully by Veratrum Viride.*—The effect of veratrum viride in diminishing the temperature, pulse, and pain in acute rheumatism, was well shown in the case of a girl aged 14, who was admitted suffering from this disease, with pericarditis. The remedy was given in the form of tincture, ten minims three times a day; but with no improvement until it was taken every four hours, when the pulse, temperature, and pains became at once reduced. Slight sickness after a few days began to accompany the employment of the drug—a not infrequent occurrence; but this at once ceased on diminishing the amount taken.

*Chronic Rheumatoid Arthritis.*—A marked example of this affection was presented in a woman aged 42, who five years previously had been seized with an acute and very painful and general affection of the joints, which, although less severe in its character, had never since ceased to afflict her. The displacement of the joints, characteristic of the disease, was well marked in her hands and knees. Since her admission, she had lost the pain in the joints, and could now move them more freely, under treatment by iodide of iron internally, and tincture of iodine externally. The wasted muscles of the limbs were now ordered to be rubbed with liniment.

*Pyæmia following Pregnancy.*—A case presenting many symptoms common to typhoid fever and pyæmia, rendering the diagnosis obscure, had just been admitted into the ward. The patient was a woman, aged 29, who had been delivered on the morning of October 6th of a seven months' child. She lay on her back, pale, rather emaciated, and with an expression of anxiety on her countenance. Her mind was perfectly clear; she was somewhat nervous, and her respiration was hurried and irregular. She was said to wander sometimes at night. She had had rigors and a good deal of pain in the right leg, referred chiefly to the knee and ankle, there being also tenderness in the leg between these two joints. These symptoms in the leg were still present, and there was distinct puffiness around the knee. The temperature was 104, and the skin was dry. There were a few small petechiæ on the chest, face, and arms, but they presented no specific character. The pulse was 108. The apex of the heart was imperceptible; the transverse dulness measured three inches; and over the cardiac region a systolic murmur was heard distinctly at the base and apex, and pericardial friction over the third left costal cartilage. The physical signs of the lungs anteriorly were good; the back was not examined. The tongue presented the appearance not unlike that found in typhoid fever—dry, brown, and with a tendency to fissure. The abdomen was not tender, but somewhat distended. The bowels had not been opened for two days; but subsequently to admission there was diarrhoea, with light-coloured motions. Dr. Murchison remarked that until the history of this case was completely obtained, it would be difficult to form a certain diagnosis; but the pain and tenderness of the joints, the rigors, the pericarditis, the endocarditis, and the fact of the woman being taken ill suddenly one week after her confinement, were all in favour of puerperal rather than enteric fever. Pericarditis and endocarditis were complications almost unknown in enteric fever. The pain in the right lower limb might suggest thrombosis of the femoral vein; but the absence of oedema, and of tenderness or hardness along the vein, the

fact that the pain was chiefly in the joints, and perhaps the fact of the right limb being affected and not the left, pointed rather to purulent deposit in the joints. He believed that the case would turn out to be an example of blood-poisoning connected with the uterus. Dr. Murchison ordered the patient a quinine and acid mixture and a dose of opium at night; but remarked that, before long, there would be an opportunity of testing the diagnosis.

### UNIVERSITY COLLEGE HOSPITAL.

OPERATIONS, WEDNESDAY, NOVEMBER 1ST, 1871.

*Extraction of Large Calculus: Unforeseen Tumours of the Prostate.*—A man named Walklate, aged 66, was brought into the operating theatre to have a large stone removed, which sometimes completely prevented his passing urine, and was the source of constant annoyance and disturbance to him. The symptoms of stone were first observed by him six years ago. Mr. Erichsen, in performing the ordinary operation of lithotomy, met with several difficulties which were quite unforeseen. The bladder lay so deep in the wound made by his knife that he could not get his finger into it. He passed a pair of forceps, however, easily enough, and seized the stone; but with a considerable amount of force he could not extract it. He tried a larger pair of forceps, but failed also with them. He passed the first pair again, and brought away what he at first thought was a piece of the prostate gland, but which proved on examination to be an enchondromatous tumour growing from the gland. The stone came after it, but required great force in its extraction. It measured in circumference  $5\frac{1}{2}$  inches, and weighed  $3\frac{3}{4}$  ounces. It was irregular on the surface, evidently phosphatic, greyish, and slightly yellow. The prostatic tumour was an inch and a half in diameter—about one-third, or more nearly one-half, of the size of the stone. In the operation, there was comparatively very little hæmorrhage. Mr. Erichsen particularly called attention to the passing of the forceps along the upper side of the staff, which was left in the bladder, when the finger could not reach the viscus. After the bladder had been syringed out, the patient was removed.

*Scirrhus Nodules.*—After several other operations, Mr. Heath extracted a number of scirrhus nodules from a man's head and face. The patient had previously had the hand amputated, and subsequently a part of the arm on account of scirrhus ulcer. Two years ago, these scirrhus nodules appeared, and it was thought desirable to remove them before they acquired great size.

### NEWCASTLE-ON-TYNE SMALL-POX AND FEVER HOSPITAL.

CORYMBO-CRYSTALLINE SMALL-POX IN AN UNVACCINATED SUBJECT: CATALEPTIC COMPLICATIONS: DEATH.

FOR the report of this case, we are indebted to Mr. H. E. Armstrong, the Resident Medical Officer.

M. A. C., a woman aged 24, having a child four months old, was admitted on August 12th. She had had small-pox nine days; the eruption was vascular and almost confluent on the face, less so on the arms, and discrete, but close, on the trunk and lower limbs. She had been delirious the previous night, till about 11 A.M. on the day of admission, when she fell into a state of profound stupor. At 8 P.M., the stupor continuing, she was lying on the left side, saliva flowing from her mouth. The respirations were 24; the temperature 100. The arms remained in whatever position they were placed; and, on placing the thermometer in the axilla and drawing the fore-arm over the chest, there was a slight spontaneous pressure of the arm against the ribs. She could not be roused; but at times coughed or swallowed saliva. While being watched by the house-surgeon, she turned suddenly on the back, and a slight movement of the ribs became apparent during respiration. She then became perfectly rigid; so that her whole body could be lifted on the bed by the left leg, which she had extended. This rigidity passed off in two minutes. In five minutes afterwards, she opened her mouth widely by convulsive jerks, causing bleeding of the upper lip. The tongue was retracted; the lower lip quivering, the upper one rigid. Shortly afterwards, she sprang out of bed, calling for her husband. At 10.30 P.M., she had the use of her limbs, and was rational, though somewhat confused. She said that during the attack just described she had been quite conscious, and remembered being lifted by the leg. She had felt no pain, except when her mouth was widely opened. She said that in the morning she had felt herself "going wrong," and found that she had no power to speak or move. She denied being subject to hysteria.

On August 13th, she had slept tolerably well; but complained of sore throat and stiffness of the mouth. There was a copious flow of thin saliva. Pulse 120; temperature (in the morning) 100; respirations 24, tranquil. She took food and medicine up to 1 P.M., when she again fell into stupor. Her right arm was noticed at 3 P.M. to be extended, and it remained in this position four hours. Pulse 120, rather feeble; temperature (evening) 100.5; respirations 24.

August 14th.—About 2.30 A.M., she rose from bed, calling out that she was the Holy Ghost, and could save every one. She was very loud, and greatly disturbed the rest of the patients. At 4 A.M., she was in a religious fervour, and for a quarter of an hour kept repeating a formula of praise to the Holy Ghost. Gradually her utterance became more rapid and less distinct, till finally her voice was inaudible, and the movement of the lips was alone perceptible. During this ecstasy, the salivary discharge caused some interruption to the above ejaculation. On the nurse remarking this, the patient made an obscene reply, and again resumed her formula. At 8 A.M., she had become filthy in her language, and spat at those about her. She made hideous faces, and uttered horrid imprecations, songs, a "jig-tune," and shuffled (as though she would dance) with the feet, which had been strapped down. She refused all food. Half a glass of brandy with water was syringed into the stomach by the nostril; and a quarter of a grain of acetate of morphia, with sulphuric ether, was ordered to be given by the nostril every hour until sleep was procured. Beef-tea and milk were also ordered to be given by the nostril. At 3.30 P.M., she had slept for three hours; waking, took willingly half a pint of milk. Pulse 128; pupils dilated.

August 15th.—She had been shouting during the night, and still required restraint. She had rubbed her cheeks against the pillow; her face was raw and bloody. Pulse 132, feeble; pupils normal.

August 16th.—She had been quiet all night, requiring the morphia mixture only once. At 9.30 A.M., she was lying quite still. Respirations 16, tolerably full; pulse small, almost imperceptible. Viscid saliva worked out at the mouth. The patient did not show any sign of intelligence.

August 17th.—She recognised those about her; and complained of cramps in the legs and back. The bowels were open. The pulse was imperceptible at the wrist, neck, or temple. As the patient lay supine, the heart-beat is not to be felt by the hand; with the stethoscope, a faint sound (apparently diastolic) was audible, 128 per minute. She had since the previous day taken food. At 7.30 P.M., she died.

At the necropsy, twenty-four hours after death, rigor mortis had passed off. The under surface of the body was hypostatically discoloured. The brain was small and soft, having the superficial veins somewhat distended. There was no appearance of variolous eruption on the brain, cord, or membranes.

REMARKS.—When the patient was first seen, the eruption was noted as somewhat corymbose, irregular patches appearing on the arms. There were also some petechial vesicles about the shoulders. These latter have been observed as a very unfavourable, and generally fatal, sign during the present epidemic. They have been more often met with in adults than in the young; and few persons that had them recovered. They are, for the most part, flat and broad—the edges only appearing above the surface of the surrounding skin—and are of a bluish-white hue. Removal of the upper wall of a petechial pock discloses a cell, containing sometimes a little fluid, generally none. The interior of the cell is of a pinkish-white colour at its circumference. In the centre of its base is a little dark blue prominence, apparently a tuft of loaded venous blood-vessels. The larger these tufts, the broader and more blue the pock, and the more malignant the case.

At a later period of this case (tenth day), the eruption on the hands and arms was pearly and globular. This condition corresponds to the crystalline small-pox of Mead and Friend, and has proved fatal in every instance in this hospital.

In this form of variola, the pocks are distended by clear fluid, and are very prominent, the central depression being absent; in some instances, even replaced by a distinct circular elevation superadded to the apex of the vesicle. The contents may turn milky, but do not suppurate. Dissection shows a dark spot or tuft of blood-vessels in the centre of the base of the pock, resembling that of a petechial vesicle. The most frequent seat of petechial vesicles is on the lower limbs; whereas the crystalline pocks have generally been most copious on the upper. The petechial vesicle has been frequently observed; the crystalline small-pox has been comparatively rare. The two kinds have been almost equally fatal; but whilst death has in the former been due to other causes, coma or some allied condition has invariably preceded the mortal termination of the crystalline small-pox.

The case under notice is chiefly interesting for the nature and sequence of the nervous complications. Catalepsy, with waxy mobility

and afterwards rigidity of limbs and continuance of consciousness, followed by ecstasy passing into obscene delirium, are of themselves of rare occurrence in the same individual; and their appearance during an attack of small-pox is probably unique.

## REVIEWS AND NOTICES.

INTRODUCTORY NOTES ON LYING-IN INSTITUTIONS, ETC. By FLORENCE NIGHTINGALE. London. Longmans, Green, and Co. 1871.

It is certainly a very remarkable thing, and not creditable to obstetrics as a science, that in 1871 the normal or ordinary, or every-day death-rate of lying-in women is not pretty well or approximately settled. When, during last year, the great discussion on Maternity Hospitals flourished in Dublin, every one must have felt the want of this piece of knowledge. Indeed, from want of it, the labours of the disputants were almost nugatory. Plenty was said, and plenty is known, of the high tides of mortality; a little was known, and much was said, of the low tides of mortality; almost nothing was known, and almost nothing was said, of the average tide. There was no standard of comparison by which to measure.

When Dr. Matthews Duncan took up the subject, he placed this point as the first to be settled, the first chapter of the work to be done. Now Miss NIGHTINGALE enters the same field, in the valuable little book before us, and starts with the following words. "The first step to be taken in the discussion is to inquire, What is the real normal death-rate of lying-in women? And having ascertained this to the extent which existing data may enable us to do, we must compare this death-rate with the rates occurring in establishments into which parturition cases are received in numbers." Had these two authors written so and been listened to when the discussion on the value of hospitals began, we should have been far advanced towards settling these disputes, and, besides, we should have been spared a deal of pointless, useless, and occasionally acrimonious talk.

The natural and simple plan of arriving at the normal death-rate of lying-in women, is to consult the reports of the Registrar-General. In Norway, it is given as 1 in 135; in Paris, 1 in 160; in St. Petersburg, 1 in 149; in Dublin, 1 in 114; in England and Wales, 1 in 189; in Edinburgh, 1 in 162; in Prussia, 1 in 108. But these data have never been regarded, within the obstetrical department of the profession, with any confidence. No doubt they have a certain value; but their value for the purposes of Miss Nightingale's book has never been admitted by the obstetrical world, and never asserted even by Registrars-General themselves. Several authors have given good reasons for doubting the accuracy of the registers, and the reasons have been invariably evidences that the registers made the mortality of women within four weeks after childbirth and during it, less than it really was. But, so far as we know, Dr. Duncan is the only author who states that he has searched the public records, scrutinising them so as to search out all the deaths during and within four weeks after childbirth. This he did for 1855 in Edinburgh and Glasgow; and he found a mortality of 1 in 107. Tarnier probably did something of the kind for the twelfth arrondissement of Paris, a poor district, and deduced a mortality of 1 in 322; a result sufficient of itself to show the inefficacy of the search, even if it had not been put out of court as fallacious by such authorities as Dubois and Danyau, who said that there was no such luck for lying-in women in the healthy and comfortable parts of that great city.

If, then, the public registers are not to be trusted, as Barnes and McClintock and others have shown, what is to be done? Every available source of information is to be sought and scrutinised; rejected or received as of some value. The authors who have attempted to do this are Le Fort and Matthews Duncan, in their respective works on Maternity Hospitals. But we fear there can be no doubt that Le Fort did not scrutinise all and reject some. He accepted all; and in doing so he has made his results of little value. To accumulate figures whose *primâ facie* aspect is false, and without giving the slightest reason for crediting or discrediting them, is not a good mode of procedure. Le Fort made the normal death-rate of lying-in women 1 in 212; that is, lower even than the death-rate of any Registrar-General. That cannot be accepted. Dr. Matthews Duncan, on the other hand, took only the data that appeared to him to be credible, as he says; rejecting those which were highly improbable or utterly incredible; and his conclusion

is, that the normal death-rate is about 1 in 120. There appears to us no way of evading the evidence which this gentleman has afforded. It is, as he says, very unsatisfactory; but it is the best that has hitherto been adduced. It is, to some extent, based on his views as to credibility; and this element in the decision should be eliminated as soon as possible. By all means, let us have facts.

Now comes the redoubtable Florence Nightingale, a host in herself; a historic medical woman, to use one of her own phrases; a great woman truly, and yet a woman; for we think we can perceive her sex even in her way of settling this knotty point, what she calls "the first step to be taken in the discussion." Women have much to do with our first steps.

Our authoress settles this first step in a very free and easy—we might say perfunctory—manner. After all the Le Fort and Matthews Duncan books and the many-toned Dublin discussions and various arrays of figures, she, without reasons given, assumes a sublime simplicity, and throws herself into the arms of Dr. Farr, the well-known English statistician, accepting, without reserve, his latest yearly result—5.1 per 1,000, or 1 in 196. Fractions at this stage of the question are over-refinement. Now, we recommend all who are interested in this great question to turn to the statements of Dr. Farr, in the fourth part (on "Developmental Diseases") of his letter to the Registrar-General of England on the causes of death in England in 1867. (*Thirtieth Annual Report*, 1869, p. 222). In this paper the reader will find that Farr does not agree exactly with Miss Nightingale. Farr gives the mortality as 1 in 200, not 1 in 196. But he adds that it varies in different years from 1 in 164 to 1 in 238; and this within recent times: an amount of variation which, considering the vastness of the figures, almost demonstrates a great amount of error, or untrustworthiness of the whole data. Dr. Farr has not entered critically on the subject of the normal death-rate of lying-in women. We are sure that, when he does, we shall have something valuable bearing on the discussion in which Miss Nightingale has joined. Her normal death-rate is not Dr. Farr's. It is simply the accidental death-rate of 1867. But Miss Nightingale shows farther want of due consideration. It is distinctly seen in the following passage taken from her judicial summing up. "In estimating (says she) the probable accuracy of statistical data in which there may be both excesses and deficiencies, sources of error are diminished by largeness in the numbers employed in striking averages." Now, the data she employs are no doubt large, and this condition adds enormously to their value, if we could get the proper key to their sources of error. Miss Nightingale has, however, quite misconceived the value of the largeness of the numbers here. It has a great value—is, indeed, invaluable, for the making of good averages. But here there is a special difficulty in attaching value to the average, for there are no excesses; there are only deficiencies, and these are certainly large deficiencies, as any one who consults the writings here referred to can indisputably prove. Miss Nightingale evidently thinks that the common rule is here good, that excesses balance deficiencies, and truth comes as the result. But there are here no excesses. Almost no deaths are entered as after childbirth, while there are many such. Many deaths after childbirth are not entered as such, intentionally or through want of care, or ignorance of what is desirable. There are numerous deficiencies. We happen to have a large acquaintance with obstetrical practice and with obstetricians, and we believe that enlightened obstetrical opinion guides us to regard 1 in 100 as much nearer the normal mortality than the English registered mortality for 1867, 1 in 196, adopted by Miss Nightingale as the normal.

But the weakest argument, yet one highly creditable to the kind womanly heart, which our authoress advances against Dr. Matthews Duncan's estimate, is the following purely sentimental one, yet ingeniously urged as if it were a logical thunderbolt. "On considering these figures" (says she), "the first impression they convey is not that either the Registrar-General or Le Fort is wrong. But it is a very painful impression of another kind altogether. One feels disposed to ask whether it can be true that, in the hands of educated accoucheurs, the inevitable fate of women undergoing, not a diseased, but an entirely natural condition, at home, is that one out of every 128 must die? If the facts are correct, then one cannot help feeling that they present a very strong *primâ facie* case for inquiry, with the view of devising a remedy for such a state of things." To which good remark we respond sympathetically, with all our heart. But this does not alter the facts.

We take leave of Miss Nightingale's work, recommending it to our readers. It is everywhere well worthy of careful perusal; and the hints which it throws out as to hospital construction and management demand the most careful consideration.

It is interesting to observe that, after all her studies and experience, this great lady does not utterly condemn maternity hospitals.

THE Subscriptions to the Association for the year 1871 became due in advance on January 1st. All which are not already paid, should be forwarded to the General Secretary, Mr. T. Watkin Williams, 13, New Hall Street, Birmingham; or to the Secretaries of Branches.

## BRITISH MEDICAL JOURNAL.

SATURDAY, NOVEMBER 11TH, 1871.

### THE HAMPSTEAD INQUIRY.

ALTHOUGH this inquiry has now ended, it may be some time before the decision of the Local Government Board can be made known on the points at issue. When it is published, it will still, of necessity, leave untouched many of the points which are of the largest public and professional interest. The absurd length of the inquiry will, we hope, act as a caution to the Local Government Board not again to involve themselves in a method of procedure which implies a tedious, costly, and unnecessary waste of public time and money. Mr. Henley and Dr. Buchanan were two highly qualified inquirers; and might with ease have settled the matter to their own satisfaction, and that of everyone else, by freeing themselves from what was after all little more than a parody of judicial form. It was not a trial; for there was neither judge nor jury present, nor judicial summing up. The able speeches made were little else than appeals to the public imagination; and a large part of the evidence was of the same character. Had the two commissioners felt authorised to adopt the more apparent and simple procedure of proceeding themselves to the hospital, reading over the depositions, and summoning such of the witnesses as seemed necessary to throw light on the facts, in order to submit their statements to scrutiny, the whole matter might have been disposed of in fewer days than it occupied weeks. As it is, the repetitions of the first part of the case so disgusted the public mind, and the tediousness with which the case was spun out so wearied public attention, that the latter part of the evidence received comparatively little attention, and very false and injurious impressions have prevailed.

The first set of witnesses included a long list of patients who had complaints to make of the meat, the milk, of the use of restraint, and of want of linen. To hear their evidence, one would have believed that the meat supplied was simply scandalous and uneatable; that the general dietaries were wholly insufficient; that there was no shadow of proper hospital arrangement or administration; that the wards were "not fit to be inhabited by a dog." In short, so black a picture of a hospital interior was never before traced. It is not a little surprising that Messrs. Greaves, Kynaston, and Aikman, should have thought fit to give to such statements an implied support, by producing them as part of their case. They must have known well how utterly faithless and unjust was such a sketch of this really admirable hospital. Their own evidence fell far short of it; and amongst the many causes of regret which the retrospect of this case must afford them, this injustice to which they have been parties can hardly be the least poignant.

Of their own course we find it difficult to say anything which shall be just, without being too severe to please us, when we consider that they are very young men, and that a stern judgment on a public error of so grave a kind might affect mischievously the prospects of their professional career. At the

very outset of their case, it was plain that they had erred very grievously in not laying any complaints which they had to make as to matters affecting the comfort and welfare of their patients before the Committee of Managers at the hospital, while the patients were still there, and while they themselves were still in active function, and capable of rendering service to those whom they represent to have suffered from neglect. The case is the stronger, in that not only did the Managers hold weekly meetings in the building in which the medical officers were lodged, but several of them were medical men, and they spent a large amount of time, sometimes many hours a day, at the hospital. If the medical officers entertained a mysterious dread of Mr. Wyatt, they need have been under no such apprehension as to Dr. Brewer; or, if they had a fear of unbosoming themselves to Dr. Brewer, they had frequent opportunities of stating their opinions, wishes, and fears, to Surgeon-Major Bostock—a man so widely and favourably known in professional circles in London, that it seems unnecessary to mention that he is not only one of the most experienced of voluntary hospital managers, but one of the most amiable and courteous of men. Failing these, there remained Dr. Jarvis, a type of polished and amiable courtesy, and Mr. Harvey, whose aspect is certainly in no way terrific. It is to us, therefore, nothing less than incomprehensible that these three gentlemen—if they really entertained the belief that their patients were suffering for the want of anything whatever, during their long period of office, and if they thought that the Medical Superintendent, Dr. Grieve, was averse to giving a just effect to their wishes—did not at any time, by word or sign, invoke for the benefit of their patients the assistance of the Managers, whose officers they were, and whom they knew to be responsible for the proper conduct of the place. It was abundantly evident that they knew of their power to invoke such aid, and of the proper means of doing so, by a brief note on the back of their daily reports, or by any other written report, supposing that they were too bashful to speak a word to the individual Managers. They even stated, in their communications to the *Times*, that they had made such reports: that statement, however, proved, at the inquiry, to be virtually incorrect. The few reports which they had made were of trivial matters, and bore no relation either to general insufficiency of dietary, to defective quality of food, to insufficiency of nurses, to the use of restraint, or to any of the grave matters which, after being called upon to resign, they charged against the administration in their letters to the daily press.

This being so, they would stand self-accused of a neglect of duty, of a violation of medical responsibility, in not exerting themselves to do justice to their patients, so grave, if these charges had been proved, that we cannot but congratulate them hardly less warmly than the public that the mass of evidence produced by the Managers showed beyond question that, read in any general sense as a description of the state of things in the Hampstead Hospital, their charges were groundless. They impaled themselves on the horns of a distressing dilemma; but we are disposed to think that they will suffer less in general estimation by the wound inflicted by this particular horn. As a matter of fact, their own admissions in cross-examination so weakened their prior statements, that it left little for the Managers to justify. Their letter was written in August, but they admitted that their complaints referred chiefly to a period which ended in June. Their complaints as to insufficiency of dietary lost all significance when they were found to be unable

to state the dietary of which they complained, and could not deny it to be one of the most liberal in existence in any hospital. Their objections to restraint, which they had set forth publicly as having been used generally in the hospital, they subsequently applied to the cases of delirious and violent patients, showing a manifest ignorance of the ordinary and necessary modes of restraining delirious persons.

As to the number of nurses, Mr. Kynaston displayed an ignorance alike of the actual proportion of nurses employed at this and at any other hospital. Mr. Greaves thought, next day, it should be one for each seven patients, as at Guy's. This was the number actually employed, when it was not one for every five or six patients.

As to the occurrences at particular dates; whether the milk-supply was on any particular day deficient; whether, by additional exertion, the Managers could have completely overcome in March the enormous difficulties with which they contended, and have supplied a fuller quantum of linen to the convalescent wards—the Commissioners must decide. All other special points we leave also untouched.

On the question whether the Hampstead Hospital, which received five thousand patients in seven months, was a good and well-conducted hospital, the evidence was completely reassuring. Dr. Bridges stated that, at eight different visits of inspection, he had found the hospital always in exceedingly good order; the wards clean and tidy; the linen of the patients as clean as was possible under the circumstances of the case; the food abundant and of good quality; and the nurses sufficient. He felt confident that the Managers discharged their duties with promptitude and energy. He had gone through the wards in company with Dr. Grieve and Mr. Greaves. Mr. J. Netten Radcliffe described the wards as excellent. His own opinion was one of unmixed admiration at the condition of those wards—particularly in February, when patients were admitted in immense numbers, and the difficulties of the Managers could only be known to one like himself. He had the same opinion as to the state of the patients and that of their linen.

Mr. Ernest Hart gave a detailed account of the result of a minute inspection on the 6th of February, and produced the notes taken at the time. The hospital had excellent general accommodation; had the great advantage of being entirely on the ground floor; had from 1,800 to 2,000 cubic feet of air for each patient, 120 square feet of floor-space for each bed, and a window between each two beds. The nurses in each ward had a nurse-room with proper cooking apparatus. Each ward had a ward-scully with hot and cold water laid on, and a bath of excellent construction. There were reception-rooms, also, with hot and cold water, and each fixed basin in the ward lavatories had hot and cold water, and a sink. There was a detached mortuary, and detached disinfecting apparatus. He found the food excellent. The beef-tea was so good that, not having had his lunch, he finished a basin of it. The bread was the Aërated Bread Company's, and was exceedingly good. The dietary was more liberal than any that he was acquainted with. The cleanliness of the wards was admirable; the linen on the beds was exceedingly clean, and the general state of the linen very good. A stain on a sheet, which appeared to be a blood-stain, was from carbolised oil, and would not wash out. The nursing in the hospital was singularly in accordance with Miss Nightingale's plan. The proportion of one nurse to

seven patients was liberal, considering the large number of convalescent inmates. He believed that the balance of medical opinion was in favour of tying down delirious patients with a folded sheet where restraint was necessary. The mortality at Hampstead was identical with that of other well-managed institutions. In all his experience, there was no hospital in this country that had admitted or had had to deal with so large a number of patients in the time, or in double the time. This hospital treated a larger number of patients in eight months than St. Bartholomew's in twelve months; and these were not equally distributed through the time, but the bulk of them were in the centre of the time. He believed everything was done that could be done by the authorities. The hospital was in every respect a model hospital; but as to the medical treatment, of course he knew nothing. He had heard nothing in this inquiry that shook his confidence in the managers.

Dr. C. A. Gordon, C.B., deputy inspector of hospitals in the army medical department, said that he was one of the commissioners appointed by the Government to observe and report on the French army. He had visited this hospital, and examined it as a non-official person would do. He formed a most favourable opinion of the cleanliness of the wards, the linen, nursing, and dietary, and could certainly say that great care was taken of the sick patients. The convalescents appeared extremely cheerful and contented. He would say that the hospital was a picture of discipline and efficiency.

Dr. John Murray stated that he had had considerable experience in hospital management, was a visiting physician of the Middlesex and Children's Hospitals, and acted as hospital reporter for the BRITISH MEDICAL JOURNAL. Whenever complaints of official mismanagement were made, he visited the hospitals before reporting upon them. He was frequently obliged to report unfavourably. He had had experience of the hospitals of France, North Germany, Switzerland, Austria, and North Italy, and had studied in Paris, Vienna, and Berlin. On seeing the letter in the *Times* he went to Hampstead Hospital, and went over it with Dr. Grieve. He questioned every nurse, servant, and assistant whom he met. He had paid many previous visits to the hospital. His opinion before these charges were brought was, and still was, that this was one of the best managed hospitals he had ever seen. In the history of hospitals, he believed no case was recorded where such perfect accommodation was afforded at such limited notice. He convinced himself that there was no ground for saying that the nursing was inefficient. The food appeared to be abundant and good.

Mr. Perry, of the Guards' Hospital, gave similar evidence.

This evidence really sets at rest all doubts as to the general state of things in the Hampstead Hospital, and leaves little more to be said. We have already expressed the opinion that, had a visiting physician been appointed in addition to the resident staff, it would have been impossible for anything to have occurred which could have given a colour to these charges. We now repeat that opinion. But we add the expression of deep regret that charges so exaggerated were ever brought forward; and that young members of our own profession should have been the means of disturbing mischievously and groundlessly the public mind, and of throwing a most unmerited odium on the managers of this great public charity, among whom were some most distinguished and self-sacrificing members of the profession to which they belong. The services rendered by this hospital have been great beyond precedent. They were ren-

dered under circumstances of extraordinary difficulty, and it would be hard to praise too highly the skill, humanity, courage, and devotion, which the managers of the Asylum Board showed in the discharge of a most arduous and protracted responsibility.

### PROPOSED BILL ON POOR-LAW MEDICAL RELIEF.

ON Tuesday night, a meeting was held at the Medical Club in Spring Gardens, convened by the Poor-law Medical Officers' Association, to consider a Bill which Mr. Corrance proposes to introduce into Parliament at the opening of the next session, for the purpose of practically placing the system of medical Poor-law relief in England and Wales on the basis of the Irish system. Dr. Joseph Rogers occupied the chair. There were present Mr. Corrance, M.P., Mr. Fairlie Clarke, Dr. Thomas, Dr. Welch, the Rev. Mr. Kitto, Mr. Safford, Dr. Stallard, Mr. Benson Baker, and many other gentlemen interested in such questions.

Letters were read from Mr. W. H. Smith, M.P., who deeply regretted his inability to be present; from Dr. Lush, M.P., who said that he felt so much confidence in Mr. Corrance and Dr. Rogers, in respect to their practical views on the subject of amending the Poor-law medical relief system, that he could promise to support the proposed Bill; and a third from Mr. John Holms, M.P., who also deeply regretted he could not attend.

The Chairman stated that a letter had also been received from Dr. Rumsey, who had been consulted with regard to the proposed Bill; and that gentleman had given the promoters of it the benefit of his practical experience. The scheme which was about to be proposed required that a case should be made out showing its necessity. In the first place, it was about to be proposed that some other authority than the Local Government Board should have the direction of the medical relief in England and Wales; and to prove the necessity for this, he enumerated statistics showing that the central authority did not even carry out its own orders so as to check the very great evil of giving most extensive districts—districts of vast area and large populations—to one medical officer. This evil, he said, was largely on the increase under the present authority of the Local Government Board; and districts extending to distances exceeding seven miles from the medical officer's house, with populations of more than fifteen thousand persons, were very numerous. All this was contrary to the Local Government Board's own regulations; and there were fully a third of all the appointments contrary to the Board's general orders. He then entered into other statistics to prove that where medical relief was at its lowest, there pauperism was at its highest; and he deduced from these figures that it would be advantageous to the country at large to have a different system with different administration.

Mr. Corrance, M.P., stated that for two months he had been working at the Bill, and had received much aid from the practical experience of gentlemen in the medical profession. The measure he proposed would not by any means be complete, or all that some gentlemen desired, but still it would cover some of the most radical defects of the present system of medical relief in England and Wales, and if he could accomplish that he should be very glad. He then proceeded to read over some of the clauses of the proposed Bill; in most of them, he said, it was similar in character to the Irish measure. He proposed that commissioners should divide the country into dis-

pensary districts; that committees should have the working of each of the districts; that the relief should be given by the issue of tickets, this issue being in the hands of a committee, generally and conjointly, so as to prevent that abuse of the system which was said to prevail in Ireland, where members of the committees, it was declared, gave the tickets to the members of their own families and to their domestic servants. He also proposed to punish persons who obtained relief without being in the position of necessitous persons. In cases of contagious disease, and in other like cases of urgency, the issue of tickets could be made by a relieving officer, but would have to be supervised by the committee within a week of the issue; otherwise, all the tickets were to be issued by the committee.

A lengthened conversational discussion ensued upon the proposals; and this was carried on by the Chairman, Dr. Stallard, Mr. Corrance, Mr. Benson Baker, Mr. Safford, and other gentlemen. In the course of it, recommendations were made in favour of, if possible, encouraging provident habits, or, rather, not discouraging such habits, by rendering medical relief altogether easily to be obtained; and Mr. Benson Baker urged, with considerable force, that the medical service under the Poor-law should, as a State service, be placed on a footing analogous to the Army and Navy Medical Services, inasmuch as there should be a competitive examination for posts, and promotion following ability and service. It was quite as important to the country, he urged, that the population should be under proper medical care, as that the soldiers and sailors should have that attention now so ill bestowed upon our poor population.

Ultimately, Mr. Corrance pointed out that all details could not be entered in the proposed measure; and the proceedings concluded with thanks to him for the Bill, which was approved, and to the Chairman.

This subject will now be taken up at an early date by the Poor-law Committee of our Association.

---

THE Queen's progress towards health has been uninterrupted.

THE yearly average of births in St. Petersburg is 19,000, and that of deaths 24,000. Of the latter, one-half occur in the hospitals.

DR. SHORTT, the Superintendent of Vaccination in Madras, has trained a number of women as vaccinators to attend on native ladies.

---

PROFESSOR HUXLEY is delivering an elementary course of lectures on Physiology at the London Institution to a crowded audience, on Mondays, at four o'clock.

---

WE direct attention to an important communication which appears to-day from a member of the Joint Committee of the British Medical and Social Science Associations concerning the reform of our sanitary system.

---

MR. DONALD DALRYMPLE, M.P., who has gone to America with a view to the examination of Transatlantic Asylums for Inebriates, has, we are sorry to learn, been attacked by intermittent fever.

---

MR. ANTONIO BINI, an Italian surgeon, aged 55, was found dead in bed on Saturday last at his lodgings near Leicester Square, having, in consequence of pecuniary difficulties, poisoned himself with strychnine.

---

THE sanitary cordon established at Iasskend, near the Arsenal, Constantinople, has been removed, and the English engineers who dwell there are at liberty to quit the infected neighbourhood. The cholera is decreasing in virulence.

PROFESSOR PARTRIDGE commenced his annual course of lectures on Anatomy to the pupils and Royal Academicians in the new theatre at Burlington House on Monday last, and will continue the same every Monday evening up to December 11th inclusive, at eight o'clock.

It is proposed to give a Course of Lectures on Diseases of the Brain and Spinal Cord at St. George's Hospital, London, this session. They will be delivered by Dr. Lockhart Clarke, F.R.S., and are optional to the students. All third and fourth year's men, however, are urged to attend.

SOME very interesting points of law and some important points of medical science have been raised in the cause of the Dublin trial of Kelly on the charge of shooting Talbot. We entirely abstain from commenting on them pending the decision of the momentous issue of life raised at the trial.

THE new part of the east wing of King's College Hospital is being rapidly completed, and a new handsome railing put round the front, with a gateway. This is a very great improvement to the old bill-poster's hoarding, which has long disfigured the front of one of our finest metropolitan hospitals. It is to be hoped the new wards will be soon occupied by needy and deserving patients, who could otherwise not obtain medical and surgical skill and attendance, and that a neatly laid out piece of ground will grace the front of the hospital.

#### APOTHECARIES' HALL.

At the recent examination for the prizes in Materia Medica and Pharmaceutical Chemistry, the successful candidates were:—1. Thomas Johnson English, of St. George's Hospital, a Gold Medal; 2. Sydney Howard Vines, of Guy's Hospital, a Silver Medal and a Book.

#### SWINDLING DIPLOMAS.

WE narrated last week the steps by which the officers of the College of Surgeons of England were placed upon the track of a traffic in forged diplomas from American Universities, which is now being carried on in London. The pending trial of "Dr. Rosenzweig" in connection with a charge of abortion and murder, has drawn attention in New York to the tricks by which a scandalous institution calling itself the "Eclectic Medical College of Philadelphia" has been and is carrying on a sale of diplomas to unqualified persons. The *New York Tribune* and the *Philadelphia Evening Bulletin* have thoroughly exposed the character of this establishment. There exists in the State a nominal power of law to put down this disgraceful traffic; we heartily hope that it will be enforced.

#### ABDOMINAL PUNCTURE IN TYMPANITES.

THE practice of puncturing the abdomen in cases of extreme tympanitic distension has recently formed the subject of some interesting communications in our pages. Sir Thomas Watson, in the new edition of his *Lectures*, refers to the subject, in connexion with mechanical occlusion of the intestinal tube, in the following terms.

"There is one further expedient which I should recommend in these trying cases, which we know (no matter how) are of necessity fatal. In cattle that are 'blown' by overfeeding on wet clover, a rough procedure, that of piercing the distended bowel with a hay-fork, has often been practised by farmers with complete success. The distress from extreme distension of the intestines by wind is so intense, the craving for relief from that distress so importunate, and the comfort from obtaining it so great, that, were I the subject of such pressing and prolonged torment, I should beg to have the inflated bowel eased by puncture with a fine trochar, even if I might (what is impossible) so lose a day or two of painful life. Since this thought was forced upon me by sufferings that I had personally witnessed, I have been gratified to learn, from a communication made to the Clinical Society by Mr. Thomas Smith, that the same thought, as was natural, had occurred to others before me, and been acted on with all the success of which it was capable; by Dr. Braxton Hicks, as well as by Mr. Smith, in this country; and by more than one physician on the Continent."

Mr. McBride's letter last week explained that it is the *rumen* which is punctured in cattle and not the bowel. We have in hand, besides

the articles already published, an interesting communication on the archæology of the subject.

#### MEDICAL OFFICERS OF THE ROYAL HOUSEHOLD.

SIR CHARLES DILKE is shocked at the large number of gentlemen holding medical appointments in connection with the Royal Household. Addressing his constituents in a speech, he observed that nothing is more singular than the constitution of the medical department. "You would hardly credit," he says, "the number of medical gentlemen who are required for the service of the Household, but I am aware that some of them are unpaid. There are three Physicians in Ordinary, three Physicians Extraordinary, one Sergeant-Surgeon Extraordinary, two Sergeant-Surgeons, three Surgeons Extraordinary, one Physician of the Household, one Surgeon of the Household, one Surgeon-Apothecary, two Chemists of the Establishment in Ordinary, one Surgeon-Oculist, one Surgeon-Dentist, one Dentist in Ordinary, and one other Physician; while the Prince of Wales has for his special benefit three Honorary Physicians, two Physicians in Ordinary, two Surgeons in Ordinary, one Surgeon Extraordinary, one Chemist in Ordinary, or more—making thirty-two doctors in one family." On further inquiry, he will find, however, that these appointments are almost entirely honorary, and that only work done is paid for, and that at no extravagant rate. We greatly doubt whether he can expect to prove extravagance in the civil list, if his information on other subjects be not more thorough than on this. The title is a public honour, and nothing would be saved to the public funds by withholding this mark of distinction.

#### PROVIDENT DISPENSARIES AND THE CHARITY ORGANISATION SOCIETY.

THE Report of the Medical Committee of the Charity Organisation Society on Provident Dispensaries has just been completed, together with the rules recommended for the management of these institutions; and will be published next week by Mr. Lewis of Gower Street. A conference of hospital authorities will be arranged, in accordance with the suggestions, for an early day in December, when Mr. W. H. Smith, M.P., Mr. Stansfeld, M.P., and others, are expected to take part in the proceedings.

#### MR. CHRISTOPHER HEATH ON CIRCULATION.

MR. HEATH forwards, at the moment of going to press, a copy of an office letter addressed to him by the publisher of the *Lancet*, referring to his recent correspondence on behalf of that journal with our publisher, and "declining to accept the challenge" which Mr. Heath has provoked, "or to furnish such evidence as his letter suggests." The publisher, however, has admitted an agent of Mr. Heath's to a private examination, and that gentleman furnishes a statement, which Mr. Heath also forwards to us, of which the effect is to certify that, judging from a partial examination of particular pages of a book in that office—the sales' book—he concludes that the weekly issue exceeds a number stated as "between four and five thousand." So childish a stratagem we do not remember to have ever seen employed. The particular pages referred to are apparently the registers of Friday's sales: the sales on the days subsequent to that of publication take up possibly a good deal of room, but are counted, of course, by units—being the sales of chance copies. So far as this vague certificate would prove anything, it proves that the circulation of the *Lancet* is under five thousand a week, and nobody can say from this document how much under. Thus the best case that the publisher of the *Lancet* can make out even by the childish piece of mystification resorted to indicates, so far as it shews anything, that the circulation of the *Lancet* is less than that of this JOURNAL, and proves, from such examination of the books as has been permitted, the original statement of our publisher. Really, the least said about so absurd a document as that which Mr. Heath has forwarded to us, the better for him. The contest was originally one between publishers, and in its present shape was not of our seeking. It was commenced by Mr. Heath. *Ab origine*, it was certainly not dignified: it

has now degenerated into the ridiculous. For the managers of the *Lancet* to allow the private agent of their chivalrous *attaché* to inspect the first page of the books, and to shut him out from the succeeding pages, was an act of cruelty greater than to refuse him access to the books altogether. It is to make Mr. Christopher Heath the victim of a transparent artifice, and the mouthpiece of a ridiculous suggestion that the other pages were comparable in any way to the first, which we are quite sure that he would have indignantly rejected if he had allowed himself to think. The challenge of our publisher remains open; and nothing could well be better calculated to support the correctness of his statement than the information as to the smallness of the *Lancet* sales, now furnished by Mr. Heath.

#### THE EDINBURGH UNIVERSITY CLUB.

THE quarterly dinner of this club was held at St. James's Hall Restaurant on Wednesday evening; Dr. Sieveking, Vice-President, in the chair. A general meeting of the members was held previous to the dinner, when a handsome silver "loving cup", subscribed for by the members, was formally presented to the club by Dr. Sieveking. The new property of the club was proved during dinner to possess a practical value of no mean measure. Amongst the guests were Admiral Belcher, Mr. Callender, and others. A number of excellent songs increased the enjoyment of the evening.

#### THE ROYAL HUMANE SOCIETY AND THE LATE DR. CHRISTIAN.

THE Committee of the Royal Humane Society, on the occasion of the lamented death of Dr. Christian, which we had recently to regret, have expressed to his widow, by formal resolution, their deep sense of the loss which the Society has sustained in the death of their late colleague, who, by his scientific knowledge and judgment, has during the last twenty years materially contributed in carrying out the philanthropic objects of the Society, and has, by untiring zeal and promptitude of action at all hours, been the means of restoring many to health who appeared beyond human assistance.

#### CHOCOLATE AND ITS ADULTERATIONS.

IN the *Annales d'Hygiène Publique* for the present month is an article by M. A. Chevallier on the adulterations of chocolate. This article of diet is, he says, the object of numerous adulterations more or less injurious to health. He had long intended to call public attention to the subject; and has now been specially induced to do so by the results of the examination of a number of specimens sold for consumption during the siege, and of which the greater number were chocolate only in name. After giving an account of chocolate, the mode of its preparation, and the various forms in which it is sold either alone or in mixture with medicines, etc., he notices the manner in which chocolate is adulterated. The ingredients used for this purpose are enumerated as follows: 1. Damaged cocoa, and the *débris* of almonds; 2. Starch; 3. The flour of wheat, maize, and of the leguminous plants; 4. Dextrine; 5. Burnt sweet almonds; 6. Gum arabic; 7. Red ochre; 8. Cocoa-shells; 9. Storax, or balsams of Peru or tolu in place of vanilla; 10. Raw sugar and powdered sugar of inferior quality; oils and fats, in place of the cocoa-butter. M. Chevallier expresses the hope that the French Government will take measures for the prevention of the frauds to which he refers; care being at the same time taken to offer no impediment to the means of improving the manufacture of an article of diet in such universal demand.

#### SUITS FOR MALPRACTICE.

IN an able article in *Hammond's Journal of Psychological Medicine*, on the Sphere, Rights, and Obligations of Medical Experts, Dr. James O'Dea of New York discusses the frequency, said to be increasing, of vexatious and ruinous suits brought against members of the medical profession. His observations have a direct bearing on similar cases in this country. We are not aware that they are increasing in frequency here; but, like other anomalies, they have an occasional tendency to

the epidemic character; and the following passage is not without interest for the professions of law and medicine in this country.

"It is said that nine-tenths of the suits for malpractice are founded on the treatment of fractures, amputations, and dislocations; and the habit of bringing them is increasing so much, that honest and capable surgeons have seriously debated the necessity of retiring from a profession whose emoluments are so scanty in comparison with its risks, and in which the hard-earned reputation of almost a lifetime may be demolished in a day. I cannot altogether acquit the legal profession of some share in the production of this feeling of insecurity among medical practitioners. It is their duty, of course, to hear the complaints of their clients; but they should see to it that these complaints are justified by the facts; and they should acquire sufficient knowledge of these facts to enable them to judge whether, even if true, they justify an action which may entail such lamentable results. Have they such knowledge? I fear not. I fear they share to some extent—to too great an extent, indeed—the popular error that whatever deformity results from a fracture is the fault of the surgeon. I think they are not sufficiently aware of the differences in the nature and termination of fractures; that in their nature they are simple and compound; that simple fractures are transverse or oblique; that *oblique fractures are the rule, transverse fractures the exception*; that the transverse get well without deformity, provided the patient obeys instructions; but that the oblique and compound almost invariably, and in spite of the most admirable surgery, leave shortening or other disfigurement; consequently that most fractures only unite at the expense of the length or shapeliness of the limb. These, with other facts of a like character, have been established by Professor Hamilton of this city, who proved, by the results of investigations conducted in a rare and exemplary spirit of candour and impartiality, that 'in fractures of the tibia and fibula, both compound and simple, perfect results are in the proportion of only one to about three of the cases treated; and, in fractures of the femur and clavicle, complete cure results in about one case in five; in fractures of the patella, a perfect cure happens only in one case in six.' Is it not time for the legal profession to have a knowledge of these facts? Is it not a reasonable hope that, with this knowledge in their possession, they will, even apart from moral considerations, lend the weight of their great influence to discountenance ruinous and vexatious conspiracies against medical practitioners?"

## SCOTLAND.

#### THE UNIVERSITY OF EDINBURGH.

ON Friday evening of last week, the students of the University met in the Humanity class-room to nominate gentlemen for the lord rectorship. As usual, the names of a large number of the celebrities and notorieties of the day (the Tichborne claimant included) were brought forward, amidst showers of peas and other customary demonstrations. The nomination of Sir William Sterling-Maxwell appeared to receive most favour with the students.

#### SIR ROBERT CHRISTISON, BART.

THE honour of baronetcy conferred by Commission on Professor Christison of Edinburgh is a just recognition of his well-earned position at the head of the profession in Scotland. Professor Christison already holds the appointment of Honorary Physician to the Queen in Scotland, and is President of the Royal Society of Edinburgh. He has received the honorary doctorate of Oxford, and has been twice President of the Royal College of Physicians of Edinburgh. He has been a Professor of the University of Edinburgh since 1822, and is the author of a work on Poisons, which, although written many years since, is still a standard authority; and of a highly esteemed treatise on *Materia Medica*. Sir Robert Christison is a Crown Member of the General Medical Council, and took a leading part in framing the authorised edition of the *British Pharmacopœia* issued by the Council. Recently, as a mark of especial esteem and respect from his colleagues in the University of Edinburgh and other friends, his bust was sculptured by subscription, and placed in the library of the University—an honour which, we believe, had not before been conferred on any professor during life.

## THE MEDICAL CHARITIES OF IRELAND UNDER THE POOR-LAW.

### II.—THE IRISH DISPENSARY SYSTEM.

THE area and population of the dispensary districts vary considerably, nevertheless the system is found to work with fewer drawbacks than any other system. The area of Ireland is 20,322,643 acres, or 31,754 square miles. This gives on an average 25,403 acres, or about 40 square miles, for each of the 800 dispensary medical officers. The population, taken at 6,000,000, gives 7,500 persons to each medical officer on an average. In cities, the area is much less and the population much greater. In some of the country districts, the area is from 100 to 200 square miles. In Bangor dispensary, county Mayo, the area is 230 square miles, with a population of 9,021 and a valuation of £5,622 : 11. This dispensary has no apothecary and no midwife. The whole of the visiting, prescribing, dispensing, and midwifery, registration and vaccination, is done by the medical officer for a salary of £110 : 8 : 9.

The election of Poor-law medical officer in Ireland is a complicated and unsatisfactory proceeding. The Commissioners require that candidates should possess a qualification in medicine, surgery, and midwifery, and be 23 years of age. If there are half-a-dozen candidates possessing the requisite qualifications, the election will in most instances be decided in favour of that candidate whose politico-religious sentiments are in accordance with the proclivities of the majority of the electors—in other words, the medical officer is not selected on the ground of his being the best physician or surgeon, but in consequence of his political and religious sentiments being reciprocated in that particular district. This of course does not secure the most able man for treatment of the sick poor under the care of the State: in Ireland especially it gives rise to ill-feeling and discontent. This system should be abolished. The entrance into the Poor-law Medical Service should be alone through the portal of competitive examination, as obtains in the army. The number of Poor-law medical officers in Ireland is almost identical with those of the medical service in the army—viz., 1,000. The annual number of vacancies has been estimated at 50 to 70. Two examinations annually, as in the army, would supply a sufficient number of men to fill the vacancies. These appointments would be awarded, both in order of time and value, according to the merits of the candidates. A knowledge of Hygiene and State Medicine should form an important feature in the education and examination of all future candidates for the Poor-law Service. This service should become a branch of the Civil Service, and be paid entirely—not half, as at present—out of the Consolidated Fund, for the reason that disease is not local but national, and not only national but international. It is surely as important that the health of the poor should be as efficiently protected as that of the army. The poor are exposed to every vicissitude of want and sickness: the army is composed of men in the prime of life, and every precaution is taken to maintain their health. If the cure and prevention of disease of the citizens be viewed from a politico-economic point of view, it becomes apparent that an efficient Poor-law medical service is as important as an efficient medical service for our combatant forces. It is important always to bear in mind to what extent pauperism is the result of disease, and to what extent both may be prevented. The service should be remodelled; the entrance should be by examination; there should be increased pay for length of service, promotion, and fixed and certain superannuation. A service without promotion affords no inducement or stimulus for its energetic pursuit.

The duties of the dispensary physician are exceedingly onerous and responsible. At the onset, he is made acquainted with the fact that he has at least thirty masters. The 800 dispensary doctors have close upon 30,000 irresponsible persons who issue orders for their attendance on the poor. The medical officer is constantly at the mercy of guardians, members of dispensary committees, and wardens and relieving officers. Those who issue the tickets, elect and pay the medical officer—hence the importance of not quarrelling with the powers that be, however unjustly they may exercise their prerogative. These 30,000 irresponsible issuers of tickets are further increased by the various members of their families, who also issue tickets. This is irregular and illegal; but it is not politic to fall out even with pseudo-authorities. The result is, as might be expected, that tickets are issued for attendance on persons able to pay for it. This demoralises the recipient, inflicts pecuniary loss on the ratepayer, and plays havoc with the private practice of the medical men in the neighbourhood; and in not a few instances with the dispensary medical officer, who in some cases is the only medical man

for miles round. The indiscriminate and irresponsible issue of dispensary tickets is the *bête noir* of the medical profession in Ireland. In the first instance it presses with unnecessary harshness on the dispensary medical officer, and indirectly on the profession generally.

From a careful inquiry it would appear that there are two causes which have operated in producing this indiscriminate issue of dispensary tickets. The first cause consists in the fact, that hitherto the Irish Commissioners have given no definition to the term "poor person". On careful consideration it will be seen that it is next to impossible to define this term, more especially in cases of sickness, for the reason that there is nothing that produces pauperism so rapidly among the artisan and labouring classes as sickness. The well-to-do artisan earning from £2 to £3 per week, with a family of five or six children, will in many instances, if stricken down with sickness, or disabled from working for four or five weeks, become an inmate of a workhouse, and if he die he leaves his family as a legacy on the rates. The other cause is within the province of the profession of Ireland to rectify—it is that a guinea is asserted to be the doctor's fee in Ireland. It is hardly necessary to state that this is not invariably the case. It is a fiction that is not infrequently used by those who are desirous of showing the supremacy of Irish over English practice. It is in reality a myth. Not a few of those who demand a guinea fee do not object to see for that one fee a patient three or four times—hence, practically, the fee is reduced to five or seven shillings. This system appears to have originated and been supported in large cities by certain members of the profession. It is at once apparent that the senior members of the profession would be consulted by the public rather than the junior, the more especially if the same fee were demanded. This operates unfairly to the younger members of the profession. The latter might, with advantage to the public and profit to themselves, accept a fee of five shillings or seven shillings for each consultation, as obtains on the continent; and the senior members of the profession should insist on receiving a guinea for each consultation. This would at once do away with the pretence that is urged as a reason for the indiscriminate issue of dispensary tickets, that the recipient was unable to pay a pound fee. Those able to pay a moderate fee would have the opportunity of so doing, to the manifest benefit of the dispensary medical officers, pecuniary advantage of the profession, and the relief to the ratepayers generally. The pound fee has been repeatedly used as an argument for the issue of dispensary tickets: this is in the hands of the profession to rectify.

The duties of a dispensary physician are that he shall attend at his dispensary on certain days and certain hours, and that he shall visit at the homes of the patients on whose behalf application is made, or elsewhere, as the case may require, etc. It is necessary that he should be furnished with a ticket signed by some person authorised to grant it; and he must not afford medicine or appliances, except in *urgent cases*, before the ticket has been presented. He must keep and duly enter the relief register. This is a simple duty in rural districts, where the patients average ten or twelve a day; but in London, should this system be introduced, where a hundred and fifty or two hundred patients a day will present themselves, it will practically be found impossible to trace each case, record the prescriptions, re-write them, and give the resultant. If this could be done, it is exceedingly problematical what useful result would be gained. None but those who are practically acquainted with the intricacy of dispensary practice, can understand the difficulty, nay, almost impossibility, of carrying out the details of this duty. Tickets are bought, sold, lent, borrowed, stolen, bartered, and hired to such an extent in cities, that their registry is a farce. The only cases where an accurate registry can be effected is that of the red or visiting tickets; and from them almost exclusively is any important sanitary information to be derived. It is well to bear in mind that the time spent in the endeavour to register these useless cases, is so much time deducted from the diagnosis and treatment of disease. Every particular entered in the register, with the exception of the disease, is, or ought to be, recorded on the ticket. The amount of clerical work imposed on the dispensary physician is as burdensome as it is useless. The dispensary porter should not be appointed unless he were able to write, and then he could keep the register, the medical officer merely adding the disease, and the apothecary filling in the prescription. It must at once be evident that it would be better both for the medical officer and the patients, that the former should follow his legitimate vocation in the diagnosis and the treatment of disease, than waste his time in entering absurd names in a book that it is impossible to keep accurately. The remuneration of the dispensary medical officers in Ireland is totally inadequate, and would be farcical if it were not at times tragical. In cities, it barely pays house-rent and taxes; and in country districts, it little more than pays for the wear and tear and keep of horses, which in most instances are an absolute necessity. It is not a little noteworthy that, wherever the district is poorest, the pay is least, the area greatest,

and the work most arduous. To some of the largest and poorest districts an island is attached, necessitating not only a horse, but a boat.

The average pay of the dispensary physician is £97 *per annum*. There are no fees for operations or for midwifery. The average value of the vaccination appointments is about £7 each, and that of registration about £14. The indiscriminate issue of dispensary tickets has destroyed private practice altogether in some districts, and in all it has very materially injured it. It is true that a ticket may be cancelled at the next meeting of the Dispensary Committee if issued to a person not entitled to it; but the Committee may not meet for weeks or even months; and as soon as the meeting is over, another ticket may be issued to the same person, which will last till the next meeting, so that cancelling is a farce. The number of persons who issue tickets could, with advantage, be greatly reduced, and responsibility should attach to all who do issue them. Tickets for out-door relief are not thus issued. The relieving officer is accountable. It has been suggested that tickets might be introduced with advantage, having a value of 2s. 6d. or 5s., and so on. The dispensing of the prescriptions costs from 4d. to 6d. In county districts where no apothecary is kept, this might be deducted for the cost of the medicines, and the balance be the doctor's fee. This would lead to a more independent feeling amongst the recipients of Poor-law medical relief, be a boon to the medical officer, and a saving to the ratepayers. Every dispensary ticket issued entails a cost for drugs as surely as the half-pound of beef or mutton, though it may not be so immediately apparent. A paid responsible officer to each dispensary district, to issue medical relief tickets, is an urgent necessity.

The condition of the dispensary houses is not always what it ought to be. In Dublin, the dispensaries are fairly adapted for the purpose intended; as a rule, they are convenient, and are provided with waiting room, dispensing department, and consulting room, with house-accommodation for the resident apothecary. High Street Dispensary, however, presents a marked contrast to the others in the city, and merits a passing remark.

It is approached through a narrow, dirty passage. The exterior is grimy, the windows are festooned with ancient dirt; where the glass is absent, boards and rags supply the place, and contribute not a little to the grotesque. On entering the waiting room, one is struck by its damp, barn-like appearance. The atmosphere in the morning is like that which any one who has visited ancient crypts would at once recognise. The consulting room partakes much of the same character. The walls here have been boarded round to the height of some four feet, in order to prevent the plaster from falling off. Above this board, the water-mark, like a tidal wave, is plainly seen. The cellar is unoccupied, and, as usual, refuse has accumulated, and a musty smell arises through the floor, and fills the room. The room above the dispensary is occupied by an amateur guano-manufacturer, under the title of a poultry yard. To the rear of the dispensary is an ashpit, etc., filled with every abomination. The water from the roof of the dispensary percolates through the heap of filth, and slowly finds its way through the cellars into the house of the resident medical officer. The house is, of course, exceedingly damp. "Abandon hope, all ye who enter here", would be an appropriate motto. Rheumatism and bronchitis are the frequent ailments of the residents. It is difficult to get a servant to remain; the one now there has a sepulchral cough, and the last porter died of fever of a typhoid character a short time ago. On lighting a fire in the parlour, a dense fog arises. Some idea of the dampness of the place may be inferred from the fact, that the glass shade suspended over the fanlight in the passage condenses the moisture, and it may be seen constantly dripping, like the dripping well at Knaresborough: this may certainly be ornamental in a wood, but is highly objectionable in a dwelling-house.

In the country districts, the dispensaries are often tumble-down houses, little better than cabins, with very little convenience for the preservation of medicines. The drugs consequently became mouldy and inert. This is the fault of the guardians. The drugs supplied are not always of the best description. This is due to the contract system in operation in Ireland. It has been found that the appointment of apothecaries to dispensaries has not only been of the greatest advantage to the patients, but has proved a saving in the cost of drugs in some instances equal to the cost of the salary of the apothecary.

In connection with the dispensary system, the establishment of "village hospitals" is contemplated, which will doubtless add greatly to the efficient working of the system. In the last report of the Irish Commissioners, attention is directed to this question in the following paragraph.

"It is our opinion that no more effectual way of protecting this country against future invasions of epidemic disease, and of affording in ordinary times effectual medical relief to the sick poor residing at a distance from workhouse hospitals, could be adopted, than by establishing

where it may be necessary what are in England called 'village hospitals,' attached to the dispensaries, and placed under the dispensary medical officer. In other words, we would, if funds were forthcoming, advocate adding to the dispensary, in populous districts remote from workhouse buildings, a village hospital, with at least two wards, one for either sex, and containing five to ten beds in each ward. The additional cost of such an establishment to the union would consist of the salary and maintenance of the nurse superintendent, and a fair addition, if requisite, to the medical officer's salary, together with the necessary furniture and appliances. As regards the cost of the buildings, such auxiliaries to the present system of Poor-law relief might fairly be considered to have a prior claim on whatever part of the surplus of the Irish Church Fund might become hereafter available for such uses. If an advance on security of that fund could at once be obtained, it would be put to immediate use in a considerable number of unions."

The midwives employed are not nearly adequate to the work to be performed. The number is being augmented year by year, but there are only 159 midwives for 1,055 dispensaries. The duties of the midwives are not well defined; and in some instances, it appears to be uncertain whether they are the superiors or inferiors of the medical officers. This not unfrequently leads to unpleasantness and inefficiency. One thing is quite clear, that the midwife is paid for attending midwifery, and that the dispensary medical officer is not paid; but in a simple, protracted, or difficult case, he enjoys the proud privilege of being responsible for the conduct of the case, and the presence of the midwife is not any excuse for leaving until the labour is completed.

The question of superannuation has, after a long fight, arrived at a very unsatisfactory result; it is but permissive, and as religious political sentiments govern the election, so the same is seen in some cases of superannuation. Permissive superannuation in the hands of Guardians has not, and cannot, escape being jobbed. The object of the Act was to enable men to retire who, on account of age or infirmity, were unable any longer to perform their arduous duties to the poor with advantage. The permissive nature of the Act is the great drawback; it ought to be as certain as in the army and navy. About thirty medical officers have availed themselves of this boon; many others would doubtless retire and make room for younger and more energetic men, if they were sure they could obtain their superannuation from their respective boards.

In fine, I cannot conclude this notice of the Irish dispensaries without bearing testimony to the courteous manner in which I was received and informed on everything pertaining to the system, both in Dublin and the surrounding country districts. I could not fail to recognise the professional ability that characterises the dispensary physicians. They have performed every operation in surgery in the cabins of the poor with the best possible results.

From their ranks, the most eminent physicians and surgeons of Dublin have come. Presidents of the Colleges of Physicians and Surgeons, and gynecologists of European reputation, have been dispensary physicians. These men have risen out of the ranks of the Poor-law service in Ireland. It is to be hoped that, under an improved and consolidated system, men of equal abilities may be induced to remain in the service, and rise by a just promotion to equal professional and social eminence.

BENSON BAKER,

*District Medical Officer, Christchurch, Marylebone.*

## SPECIAL CORRESPONDENCE.

### LIVERPOOL.

[FROM OUR OWN CORRESPONDENT.]

*Royal Infirmary School of Medicine.—Vacancies at the Infirmary.*

THE Royal Infirmary Medical School commenced the present session under very encouraging and favourable auspices. Thirty fresh men entered for registration in October, making a total of seventy-one students in actual attendance on the classes—a greater number than has hitherto been reached in the annals of the school. As these numbers (for the accuracy of which we can vouch) do not correspond with the figures published on the authority of the Government Inspector in the JOURNAL of the 4th November, it is necessary to explain that the returns made to the Inspector include those students only who are attending the anatomical classes, not giving a full list of new entries, nor of a considerable number of men actually on the school-books. The report alluded to represents Liverpool to have fewer students this year than in 1870—the fact being that, as already stated, there is a marked increase over the last and every preceding year.

The progress of the school, as shown by the continuous increase of

students during the past few years, indicates the success which has attended the efforts of the lecturers to develop to the utmost the abundant resources for medical teaching which exist in our large provincial towns, and shows at the same time the extent to which the rising generation of medical men appreciate and avail themselves of the facilities and special advantages which properly conducted provincial schools afford to those students who desire to pursue their studies and complete their medical education in their own locality.

The school-premises, originally spacious and commodious, have during the recess been extended by the addition of a separate class-room, fitted up with osteological specimens under the direction of Mr. Banks, the lecturer on anatomy, devoted chiefly to junior students for the purposes of study and special demonstrations; and new and more complete and convenient lavatories have been added to the dissecting-room. Further improvements are in contemplation, comprising the erection of a larger museum, a new library, an additional chemical laboratory, and a class-room for physiological demonstrations—all of which are rendered necessary to meet the growing requirements of the school. The plans for these proposed alterations are already drawn out; and it is hoped that the work may be completed before the commencement of another winter session.

Important changes have recently taken place in the medical staff of the Royal Infirmary. Dr. Inman has resigned, and is succeeded by Dr. Waters, whose experience and acknowledged ability and success as a clinical teacher while physician to the Northern Hospital cannot fail to render his appointment acceptable and valuable both to the infirmary and to the school. Dr. Vose, the senior physician to the Infirmary, has also resigned; and, although we can scarcely grudge him the repose to which nearly thirty years' active service fairly entitles him, we cannot but regret that the hospital should so prematurely suffer the loss of a physician apparently still in full health and vigour, whose gentlemanly bearing and high professional tone well sustained the dignity of his office, and whose unvarying kindness and courtesy and the conscientious discharge of his duties to his patients and to his pupils, will be long and gratefully remembered by a wide circle of friends and *quondam* students.

For the vacancy thus created at the Royal Infirmary three candidates are already in the field: Dr. Glynn, demonstrator of anatomy at the school and physician to the Northern Hospital; Dr. Dickenson, a young physician of much promise, the son of the late Dr. Joseph Dickenson, who held a high position and was very popular as a consulting-physician in the town, and who held for many years the office to which his son now aspires; and Dr. Davidson, lecturer on pathology at the school and assistant-physician to the Children's Infirmary, whose position and merits fairly entitle him to put in a claim. It is anticipated that the struggle will be between the first two candidates. With three such candidates before them, the trustees cannot fail to secure a good man. If Dr. Glynn should be selected, there will remain vacancies for two physicians at the Northern Hospital; and to many disinterested parties it seems that a satisfactory compromise might be made, which would place these three gentlemen in positions to utilise and develop the high professional attainments which they undoubtedly possess.

## REPORTS OF SOCIETIES.

### CLINICAL SOCIETY OF LONDON.

FRIDAY, OCTOBER 27TH, 1871.

WILLIAM W. GULL, M.D., LL.D., President, in the Chair.

MR. HULKE exhibited a blacksmith, from whom, in August 1870, he had removed, in the Middlesex Hospital, by excision and cauterisation, a very large Rodent Cancer of the left side of the face. It had eaten away the whole lower eyelid and part of the upper one; it had also invaded the orbit and destroyed the eyeball, and opened the frontal sinus and nasal passages. The patient returned in August last with two small growths of the size of a threepenny-piece. These were destroyed with zinc-paste, and the whole surface now seemed perfectly healthy. There was now a large hollow, lined with healthy mucous membrane, showing the lower and middle turbinated bones, the openings into the frontal sinuses and nasal passages and the antrum. This chasm could be hidden by a mask. Mr. Hulke said that the danger of operating in these advanced stages was overestimated, and that with care the actual cautery and a chloride of zinc-paste could be safely used, even to the roof of the orbit.

MR. G. LAWSON exhibited a patient from the Middlesex Hospital on whom he had operated successfully for a Rodent Cancerous Ulceration, involving the upper eyelid and extending into the orbit and on to the side

of the nose. On account of the extent of the disease the eye was first excised, and then the whole of the diseased structure was removed with a scalpel. The bleeding having been arrested by the actual cautery, the chloride of zinc-paste, spread on pieces of lint, was freely applied to the cut surface; a layer of cotton-wool was then laid over the parts, and the whole was kept *in situ* by a turn of a bandage round the head. The patient suffered comparatively little from the operation. The pain which she had was relieved by a subcutaneous injection of morphia. Large sloughs soon came away, and portions of the bony walls of the orbit exfoliated, and ultimately the granulating surface of the wound cicatrised. There was now a large gap, showing the upper portion of the nasal cavity and some of the ethmoidal and frontal cells; but the parts were all healthy and cicatrised, and there was reason to hope there would be no recurrence of the cancerous ulceration.—MR. HULKE, in answer to the PRESIDENT, said that the zinc-paste was prepared by mixing the zinc with honey and opium.—In answer to Dr. MOXON as to whether the disease was really cancerous, Mr. HULKE proceeded to describe its minute structure. It was composed chiefly of small round spherical cells like those of rete mucosum without intercellular substance, and, although differing from epithelioma, resembled it so far that he could not draw a sharp line of distinction between the two.—MR. BERKELEY HILL alluded to a case in which the disease had been arrested by nitrate of zinc. The disease had, however, ultimately returned.—MR. HULKE remarked that there might be again and again a recurrence of the disease, but this depended on incomplete destruction of the disease.—DR. SEDGWICK pointed out that the zinc, when used with glycerine, was apt to run, as the glycerine drew much water.—MR. LAWSON observed that a compound of chloride with oxide of zinc formed a powder, and could be applied to little spots if required.—MR. DE MORGAN said that at the Middlesex Hospital it had been found that the chloride of zinc-paste did not run, but formed a very dry surface. He expressed the opinion that we could hardly deny to rodent ulcer what we denied to epithelioma, the difference between the two in gland-affection being perhaps due only to the local condition of the disease, and not depending on the presence or absence of malignancy.—MR. HULKE remarked that the depth to which the zinc was to act could be regulated by the quantity used.

DR. C. THEODORE WILLIAMS related three cases of Phthisis, in which contraction and rapid obliteration of cavities had taken place. The patients were two females and one male, and their respective ages were 15, 53, and 27. They had symptoms of phthisis for periods varying from six to twelve months; the disease being for the most part limited to the upper lobe of one lung, where unequivocal signs of a cavity had appeared. The first was a case of caseous pneumonia, where the cavity became obliterated in two months, and the patient has since remained free from cough for more than one year. In the second case, which, from the great prostration, excessive night-sweats, and aphthous state of the mouth, was regarded as unfavourable, the disease followed pleuropneumonia, and closure of the cavity was complete in three months. In the third case the patient had fistula, followed by scrofulous pneumonia; and a large tinkling cavity, involving the whole upper lobe of the right lung, formed, which became obliterated in two months, cavernous sounds being no longer detected. All three patients were free from family predisposition. They took cod-liver oil, with tonics, and enjoyed a liberal diet. Dr. C. T. Williams remarked that contraction had taken place with unusual rapidity in these cases; and the remarkable feature was, that it gave rise to little or no displacement of the neighbouring organs, and to no marked collapse of the chest. He therefore concluded that the vacuum created by the shrinking of the cavities must have been supplied by an expansion of the lung-tissue round the cicatrix. The obliteration in two months of a cavity sufficiently large to give tinkling sounds was an exceedingly rare occurrence.—DR. HABERSHON expressed a doubt as to the cases narrated being examples of cavities healed up, and pointed out that there was no good reason to believe that they were other than cases of local pneumonia.—DR. C. J. B. WILLIAMS pointed out that in the third case there was metallic tinkling, and therefore a large cavity. He had never seen a case in which the symptoms of obliteration were more manifest.—DR. MOXON expressed himself as dissatisfied with the cases, as the report did not prove the existence of cavities to others. He had often heard cavities in the living subject, but found solid lung after death.—DR. DOUGLAS POWELL had no doubt as to the existence of cavity.—The PRESIDENT was of opinion that we could not make a diagnosis of a foreign cavity in the lung, and alluded to a case of pleuropneumonia with cavernous sound and consonating bronchophony at one spot. The place was marked with nitrate of silver, and after death no cavity was found.—DR. C. J. B. WILLIAMS observed that if the intensity of the sound were appealed to, the listener would be deceived; if the apex was entirely solid and led to the trachea, the sound was obtained as loud as

over the trachea itself; but it was not loudness that produces pectoriloquy, but the character of the sound. Besides, the history of the case was different from that of consolidation.—Dr. THEODORE WILLIAMS, in reply to Dr. HABERSHON and Dr. MOXON, stated that the diagnosis of the existence of a cavity in these patients was confirmed by several examinations made by his colleagues and himself.

#### MEDICAL SOCIETY OF LONDON.

MONDAY, OCTOBER 23RD, 1871.

ANDREW CLARK, M.D., President, in the Chair.

MR. SPENCER WATSON showed a case of Traumatic Dislocation of the Crystalline Lens into the anterior chamber. The lens was extracted through an incision in the sclerotic, at the lower and outer side. The result was good, useful vision being retained four months after the operation. He also showed a case of Congenital Displacement of both Lenses in a child, aged 14. When the pupils were natural in size, the irides were tremulous; and when the eyeball was moved inwards, the pupils became oval, and the plane of the iris near the pupil was obliquely inclined on the inner side, as if from the lens pushing it forwards at that part. There was slight divergent squint, and the child's aspect was peculiar.

Mr. HENRY SMITH related an interesting case of Lithotripsy followed by Lithotomy. The patient was a healthy country gentleman, aged 70. The bladder was healthy and tolerant of the sound, the urethra capacious, and the stone of a size convenient for crushing. The stone was seized without trouble, and crushed in a few seconds. In forty-eight hours, violent inflammation came on, and his life was placed in peril. In ten days, he was free from danger. Lateral lithotomy was performed, and he speedily recovered.—Mr. BRYANT called attention to the extreme importance of a course of sounding. In stricture and stone in the bladder, especially in the latter, the passage of a sound might set up urethral fever. In a case of stone for which lithotripsy was proposed, he sounded several times. On the third occasion, the lithotrite failed to detect the stone, and the operation was postponed. Rigors and much constitutional fever set in, and the patient died on the fifth day. Disease of the kidneys was present.—Mr. SMITH, two years ago, had in King's College Hospital a strong, healthy, agricultural labourer, with a small stone in his bladder. The stone was taken up with a lithotrite, measured, and let fall again, no violence having been done. Severe inflammation ensued, followed by death in ten days.

Mr. SPENCER WATSON showed an apparatus for applying Dry Cold to the Eye. Ordinary India-rubber air-balls were filled with water and placed in a basin containing iced water, and applied to the eye, being changed at intervals.

Mr. JOHN GAY read an abstract of his paper on Hypovenosity of the Lower Limbs. This has already appeared in the JOURNAL.—Mr. DE MÉRIC, Dr. ROUTH, Mr. BRYANT, and Mr. WEEDEN COOKE took part in the discussion.

MONDAY, OCTOBER 30TH, 1871.

ANDREW CLARK, M.D., President, in the Chair.

MR. DE MÉRIC related a case of supposed Fibroid Phthisis following an injury. The patient, a man aged 45, had had some of the lower ribs in the right side broken, near their angles. Some days after the accident (having up to this time apparently gone on well) he had hurried breathing, some pain in the left side of the chest, restlessness, anxiety of countenance, and abundant expectoration. On the eleventh day he was in a typhoid state; the whole left side of the chest was dull on percussion, and no breath-sound could be heard in it. At the end of two months the patient left his bed. About ten weeks after the accident gurgling began to be heard towards the apex of the left lung, and gradually assumed the character of the sound of air passing through a small vomica filled with fluid. The patient died on the nineteenth day after the accident. The right lung was found collapsed, filling about two-thirds of the cavity. It contained several circumscribed tubercular deposits of various sizes. The left lung formed a solid mass of tuberculous solid infiltration, without trace of vessels, air-tubes, or air-cells. There was no suppuration and no vomica. The heart was atrophied. There was no family history of phthisis; but it was difficult to conceive that the infiltration would be so extensive if some previous pathological change had not been present.—Dr. DOUGLAS POWELL could not understand why this was called a case of phthisis; he would consider it one of pneumonia in the grey stage.—The PRESIDENT said that if there were no cavity there was no phthisis. The specimen was an excellent example of the hard form of grey pneumonic consolidation.

Mr. JOHN PENNEFATHER read a paper on the Sense of Hearing.

Experiments with the air-pump had proved that a vacuum surrounding a body rendered it incapable of emitting sonorous vibrations; that sound was produced primarily by the vibration of a sonorous body; but that the composition of that body, and the atmosphere surrounding it, materially affected the radius to which the pulses of sound were transmitted. The pulses of sound were conveyed in undulating waves, which were fully illustrated by casting a substance into the water; the circular undulations gradually expanded until the inceptive force was expended. But, on coming into contact with an unyielding structure, the ripples leaped up and surrounded it, again uniting, but with increased force. Should there be a hollow space in the fixed object, the water rushed in with increased violence; so in the sonorous undulation of sound, as the pulses reached the side of the cranium, they surrounded and rushed into the entrance of the external ear with augmented power. Allusion was then made to the way in which the sonorous vibrations might be directed to a given point by reflectors. Mr. PENNEFATHER traced the comparative anatomy of the organ of hearing, from its first rudimentary structure to its perfect development in the mammalian class, showing what was essential in the organic structure for the true reception of sound, and the perfect realisation of the sense. The manner in which the sonorous waves were transmitted to the internal ear was explained. The author contended that writers on this subject were in error, in supposing that the bones of the head or the air contained in the tympanum had any power of conduction, unless the sonorous body were in actual contact with the cranium. The structure of the internal ear with the rods of Corti was then explained and demonstrated, both by microscopical preparations and plates.—A discussion ensued, in which Dr. ROUTH, Dr. SYMES THOMPSON, and Dr. DALBY took part.

Mr. TEEVAN then showed some instruments.

## ASSOCIATION INTELLIGENCE.

### METROPOLITAN COUNTIES BRANCH.

A SPECIAL General Meeting of this Branch will be held at 37, Soho Square, on Tuesday, November 14th, at 4.30 P.M., to take into consideration certain alterations in the Laws of the Branch, proposed by the Council.

A. P. STEWART, M.D.

ALEXANDER HENRY, M.D. } *Honorary Secretaries.*

London, November 1st, 1871.

### SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEDICAL MEETINGS.

THE next meeting of the members of the above District will be held at the Fountain Hotel, Canterbury, on Thursday, November 23rd, 1871, at 3 o'clock. The Chair will be taken by the President of the Canterbury Medical Society.

Dinner will be provided at 5 o'clock precisely. Charge, 5s., exclusive of wine.

All members of the South Eastern Branch are entitled to attend, and to introduce friends.

Gentlemen who wish to make communications to the meeting, are requested to inform me *at once*, in order that a notice thereof may be included in the circular convening the meeting.

CHARLES PARSONS, M.D., *Honorary Secretary.*

2, St. James's Street, Dover, Nov. 7th, 1871.

### SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT MEDICAL MEETINGS.

THE November meeting of the members of the above District will be held at the Old Ship Hotel, Brighton, on Friday, November 24th, at 3.30 P.M.; Dr. ALFRED HALL in the Chair.

Dinner will be provided at 5.15 P.M. precisely. Charge (not including wine), 5s.

All members of the South Eastern Branch are entitled to attend, and to introduce professional friends.

Gentlemen who propose to stay to dinner, are requested to inform me the day previously.

Gentlemen desirous of making communications to the meeting, will oblige by giving me an early intimation, in order that notice thereof may be included in the circular convening the meeting.

THOMAS TROLLOPE, M.D. Cantab., *Hon. District Secretary.*

35, Marina, St. Leonard's-on-Sea, November 8th, 1871.

## BATH AND BRISTOL BRANCH: ORDINARY MEETING.

The first ordinary meeting of the session was held at the York House, Bath, on Thursday evening, October 26th; CROSBY LEONARD, Esq., President, in the Chair. There were also present thirty-eight members and three visitors.

*New Member.*—J. B. Fry, Esq., of Swindon, was unanimously elected a member of the Association and of the Branch.—Three other members were nominated, and will be balloted for at the next meeting.

*Papers.*—The following papers were read.

1. On the Use of Chloral in Puerperal Convulsions. By J. G. Wayne, M.D. Messrs. Prichard and Leonard made some observations.

2. Notes on Pneumothorax. By H. F. A. Goodridge, M.D. Dr. Budd offered a suggestion.

3. Intraocular Myotomy. By A. Prichard, Esq. This paper elicited much discussion, in which Messrs. Mason, Dobson, Smith, the President, and others, took part.

4. The Employment of Setons in Treatment of Strumous Diseases. By E. Crossman, Esq. Drs. E. L. Fox, Davey, and Spender, discussed this question.

The meeting closed with a vote of thanks to the gentlemen who had read the papers; and a special request that they would send them to the JOURNAL for publication.

## CORRESPONDENCE.

## OFFICERS OF HEALTH AND UNION MEDICAL OFFICERS.

SIR,—Some remarks recently made in a leading article of a medical contemporary, on "Officers of Health and Union Medical Officers," are calculated, as far as the influence of that periodical extends, to promote an entire misconception of the reforms which Mr. Hastings and the "Joint Committee" recommend.

I prefer commenting on that article in the BRITISH MEDICAL JOURNAL, as having many more readers in the provinces, to which alone the plan of the Social Science and the British Medical Associations, and the counter project of the Royal Sanitary Commission, apply. I, therefore, beg the favour of sufficient space to place the question fairly before your numerous readers.

The evidence taken by the Royal Commissioners, as also their Report, are decidedly against the unwise suggestion of your contemporary—to *debar the Poor-law Medical Officer from private practice*. So are all the best authorities on the subject, from the time when this absurd and mischievous suggestion was first put forth by official people, more than thirty years ago. Fortunately, an opinion adverse to it has been pronounced by Mr. Lambert (*Evid.* 4741), whose appointment as Secretary to the Local Government Board is a matter for general congratulation. Mr. Ceely, of Aylesbury, also a high authority on such a question, said in 1844, before the Medical Poor Relief Committee (*Rep.* p. 604):—

"I think that the union of private with public practice is desirable; first, that it is more satisfactory to the poor; secondly, that it is beneficial to them to have the advantage of the long and varied experience of established practitioners; thirdly, that it is beneficial to the rate-payers on the same grounds; it is equally beneficial to the rate-payers also to have the advantage of medical experience gained from an attendance on the poor, more particularly during the prevalence of epidemics, which generally attack the poor early, and in large numbers; and the separation of the appointment from private practice is more expensive, particularly in rural districts, if the districts are of the proper size."

No doubt the reproducer of this objectionable proposal found that the arguments brought forward by the Joint Committee, and adopted by Mr. Hastings, against the union of private practice with the duties of the superior Health Officer, were perfectly unanswerable. The only method of escaping from their conclusions, and at the same time of helping the Sanitary Commission to defeat their well-considered plan, would seem to be to impose Poor-law curative duties on the preventive functionary, and then to debar this compound officer from attendance on the remunerating classes of society.

This *tertium quid*, of course, involves the necessity of reducing the area to be committed to the Health Officer, while considerably extending the area of the medical relief district. Now, if there be one complaint against the present Poor-law Medical System better founded than another, it is that the medical relief districts, in many places, are already

too large for prompt attention to acute cases, and that the lives of the sick and hurt poor are often imperilled, if not sacrificed, owing to their difficulty in obtaining prompt assistance from a distant medical officer.

Ought, then, this serious peril to be largely augmented by a theoretical change, of a most expensive nature? That the cost of the plan would be enormous, is plain; for we may safely assume that no well-qualified medical man, debarred from other sources of professional income, and required to find the means of travelling over an extensive district, could live decently on a salary of less than £500 a-year. Now, if the medical attendants on the poor were reduced in number by one half, the cost of the 1600 who would then be employed in the double capacity would amount to no less than £800,000 *per annum*, in addition to the cost of drugs and dispensaries; for the introduction of the Irish system may now be considered inevitable. Can any one in his senses suppose that Parliament would sanction such a project?

On the other hand, for about half that sum, the plan of the Associations might be carried into effect, with liberal treatment of all the medical agents. The present 3200 district medical officers, performing certain sanitary functions, might receive each, on the average, nearly £100 a year—drugs being provided by the public; and every chief officer of health, debarred from practice, who would be required on that plan, might receive from £800 to £1000 a year.

There can be no doubt as to which of the two projects would be best for the poor, the public, and the medical profession. To reduce the cost of the former extravagant proposal to the amount of our estimate for the latter more reasonable plan, it would be necessary to reduce the number of the proposed compound officers to 800; that is, to dismiss three out of every four of the present district medical officers!

Who that knows anything about the medical care of the poor in provincial districts would suggest so cruel and unjustifiable a scheme?

Now, one of the notions of the writer whom I am criticising is, that the district placed under the care of the Medical Officer of Health "should not be a very extended area." This is a vague expression. But, if it mean that the officer should be enabled by the smallness of his district to carry out a system of domiciliary visitation, sickness, registration, and personal investigation of local causes of disease, and to report thereon—these are precisely the duties which the Joint Committee and Mr. Hastings propose to commit to the present district surgeons, acting as Deputy Health Officers; and they are duties which can be performed, efficiently and thoroughly, only by those who are backed and protected by a superior Health Officer made independent of practice.

They are duties, also, which, being performed by the proposed deputies, would enable the chief officers to undertake, with great advantage to the public, certain duties of a different kind in "a very extended area".

But, to question our opponent more closely, what does he propose as the limit of population to a district under *his* officer of health? We know what those best qualified to form an opinion on this point have said. For instance, Dr. Ballard, who has been deservedly promoted to an inspectorship, and whose practical experience is great, has suggested that a highly qualified officer of health might superintend a population of 200,000. Dr. Lankester is known to have advised ten or twelve such officers, debarred from private practice, for the whole metropolitan area, which would assign nearly 300,000 to each. Dr. Strange of Worcester, one of our oldest sanitary reformers, believes that 250,000 might be properly superintended, even in the counties. Mr. Dyke, the able officer for Merthyr, proposes 100,000 for a country district. Dr. Rumsey has given reasons for an average of 135,000. Dr. W. Budd thinks that a third or even half of a large county might be thoroughly dealt with by an accomplished officer. These are men whose opinions are entitled to some weight, and who might have been expected to influence the decision of the Royal Commission. They all contemplate the *twofold* organisation which the Associations propose. And it is curious to observe how the writer in question avoids all reference to the *two grades*; how he opposes the project of chief health-officers by arguments which properly apply only to district medical officers; and how he would convert the latter into officers of health of a single grade, either by leaving the higher responsibilities and duties unfulfilled, or by committing them to government inspectors, the number of whom would, in that case, have to be vastly increased, involving the necessity for further national expenditure. What those higher duties of the sanitary appointment would be, members of the Joint Committee have sufficiently explained; but I may mention the more obvious: 1. The collection, revision, and compilation, of the returns of sickness and mortality and of their causes, to be made by the registrars, deputy health-officers, and medical charities, in an extensive area; 2. The visitation of hospitals, dispensaries, asylums, and industrial establishments, which might be permitted, if to be performed by an independent officer over a wide district, but would never be tolerated if committed to the small

compound officer proposed in the *Medical Times and Gazette*; 3. Inspection in difficult cases referred to such an officer by the district deputies—e.g., "Nuisances arising from commercial and manufacturing processes of magnitude and involving important interests"; and 4. Advice to county authorities in cattle-murrains, to sea-port authorities in the threatened invasion of pestilences, and generally in grave emergencies affecting the health and safety of large populations. These, among others, are duties which could, with propriety, be committed only to a grade of officers of which your contemporary seems to have no idea. His project might possibly, though not advantageously, be adopted in London, and perhaps a very few other great centres of population; but to propose it for the provinces, containing nearly six-sevenths of the people of England, is merely to afford another instance of the unfitness of persons, influenced only by metropolitan views and associations, and knowing little practically of the country, to judge of what is required for the whole population.

I would notice one more advantage of the project of the Joint Committee; namely, that vacancies in the higher grade might be filled by the most deserving officers of the lower grade in each county. The same hope of promotion which leads to distinction in the army, navy, and civil service, might be beneficially extended to the local government medical staff, and tempt men of mark to enter the civil medical service. An honourable ambition as well as a sense of duty would then encourage skilful and laborious effort.

I am, etc.,

Nov. 2, 1871.

A MEMBER OF THE JOINT COMMITTEE.

#### THE DISCUSSION ON PROLAPSUS AT THE OBSTETRICAL SOCIETY: DECAPITATION VERSUS EVISCERATION.

SIR,—I have been unfortunate in being misunderstood upon both these subjects. In your editorial notice of the discussion on prolapsus uteri on the occasion of Dr. Conrad's excellent paper in the Obstetrical Society, you represent "Dr. Barnes to have asserted that prolapsus never occurred in the multipara." What I said, or at any rate meant to say, was very nearly the reverse. The subject-matter was hypertrophic elongation of the cervix uteri. This, I believe, rarely, if ever, occurs except in women who have borne children. Having stated this as a general fact, I thus proceeded to explain my view as to the mode in which labour acted as the primary cause of prolapsus and hypertrophy. As this will be no doubt fairly reported in your proceedings of Societies, it is unnecessary to repeat it here.

The other point for correction arises out of a note by Mr. F. W. Wright in the *BRITISH MEDICAL JOURNAL* for October 21st, entitled, "Should Evisceration ever be Performed in Arm-Presentations?" Mr. Wright quotes Churchill as condemning decapitation, and goes on to say: "Dr. Barnes, it would appear, gives the preference to evisceration, for he says that 'Sometimes perforation and evisceration are insufficient in themselves, and another step will be necessary in order to complete delivery. This ultimate step is decapitation.'" To stop here would convey an erroneous idea of my views. Mr. Wright ought properly to have completed the last sentence he quotes from my lectures on Obstetric Operations, 2nd edition, p. 217. There is no full stop after "decapitation"; the sentence goes on: "an operation of extreme importance, capable of bringing almost instant relief and safety to the mother." I then quote with full assent the opinions of Drs. Davis and Ramsbotham in favour of decapitation; and devote seven pages and three original illustrations to the description of the operation. The passage imperfectly quoted by Mr. Wright was simply the expression of some clinical experience I had had of the matter. I have been called to cases where, perforation and evisceration having been performed, delivery was still not accomplished. In these cases, I have decapitated and delivered with so much ease and celerity as literally to justify the words, "an operation capable of bringing instant relief and safety to the mother."

However, whilst according a decided preference to decapitation, I do not think that perforation of the chest, and pectoral and abdominal evisceration, should be altogether discarded. Sometimes the neck is very difficult to reach so as to fit the hook, a string, a wire, or other decapitating instrument round it; and sometimes the natural process of spontaneous evolution or doubling up is so advanced that nothing more than perforation of the bulging side of the chest is required to facilitate the completion of the process. Sometimes, with or without perforation, the doubling up of the foetus may be promoted by cutting through the most prominent part of the vertebral column with scissors. The arch being thus broken, the body doubles up easily, or, a leg being seized, delivery, by drawing down the inferior part of the trunk, becomes a simple matter. Since these proceedings are designed in prosecution of

a course in pained, and often successfully carried out, by Nature, it seems to me unwise to condemn them absolutely. "Ni toujours, ni jamais", is an excellent maxim that finds a good application here.

I am, etc.,

ROBERT BARNES.

31, Grosvenor Street, November 4th, 1871.

#### MR. HEATH ON CIRCULATION.

MR. HEATH asks us to publish the following correspondence:—

9, Cavendish Place, Cavendish Square, W.

1st November, 1871.

SIR,—Certain members of the Committee of Council of the British Medical Association, which met yesterday at Birmingham, and before which I brought certain correspondence between myself and the publishers of the *BRITISH MEDICAL JOURNAL*, having expressed doubts as to the circulation of the *Lancet* being larger than that of the journal in question, I shall be much obliged if you will put in my hands evidence to show that the weekly circulation of the *Lancet* far exceeds that of the *BRITISH MEDICAL JOURNAL*, which may be assumed to circulate between four and five thousand copies per week.—Your obedient servant,

CHRISTOPHER HEATH.

The Publisher of the *Lancet*.

The *Lancet* Office, 423 Strand, London, W.C.

November 6, 1871.

DEAR SIR,—As we do not intend to exhibit our books to our contemporaries, or to enter upon a contest which at the best would be a very undignified one, we can neither accept the challenge which has been given, nor furnish such evidence as your letter suggests. For your own private satisfaction, however, the books are open to the inspection of your solicitor, who will at once see that your statements, in reference to the matter, are abundantly borne out by the facts and figures of each week.—I am, dear sir, yours respectfully,

J. CROFT.

C. Heath, Esq.

3, Langham Place, Portland Place, W.

9th November, 1871.

DEAR SIR,—According to your request we have inspected the weekly sale-book of the *Lancet*, at the office of that journal, and find that about seven pages of that book are devoted to each week's sales of the paper.

We have investigated the first page only of six weekly accounts in the present year, selected by ourselves at random, and find that each of such first pages shows sales effected to the publishing firms named therein, to an amount exceeding by several hundreds the number of copies you stated to us as the weekly circulation of the *BRITISH MEDICAL JOURNAL*.

These numbers are, of course, quite irrespective of the copies sold to firms whose names appear in the six remaining pages of such weekly sale accounts.—We are, dear sir, yours very faithfully,

C. Heath, Esq.,

LEATHES AND MAYNARD.

9, Cavendish Place, Cavendish Square.

#### LIP-READING BY THE DEAF AND DUMB.

SIR,—In your interesting article on "The Education of the Deaf and Dumb by Lip-reading and Articulation", several statements occur which call for remark. The system sought to be introduced by Mr. Van Praagh is by no means "new", nor was it "originally English". It had its origin in the writings of Dr. Ausman, a Swiss physician, published A.D. 1692-1700. Contemporary with him was Dr. Wallis, one of the earliest English writers on the subject. Samuel Heinicke founded a school at Leipsic in 1778, taking Ausman's works as his guide; and about the same time schools were established in England and Scotland on the sister method, as taught by Wallis and others.

"The education is commenced at the age of seven, and it extends over a period of seven or eight years." It should have been added that two preparatory years are passed in acquiring the elements of words, making a total of ten years. This is a serious disadvantage, when we consider that the greater part of the deaf and dumb belong to the poorer class, who must early begin to earn their own living. The sign- and finger-talking system requires no time for preparation; and throughout its course knowledge is conveyed much more rapidly than by lip-reading. We should thus suffer a clear loss of two years at the least in adopting the former method.

"It is not found difficult to obtain instructors." To meet with persons able and willing to undertake the arduous task is very difficult indeed. No system can do away with the fact that there are peculiar difficulties to be overcome in educating the deaf; and unless we are content to produce a speaking automaton when we might draw forth a living soul, we must conform our methods to their need, and not to our own convenience. Signs must be used in either system at the commencement; but in both they are wanted less and less as the pupils advance

in language. It remains to judge whether we should really benefit our deaf and dumb by withdrawing from them the means of a full education and giving them a fragmentary one in its room; for fragmentary it must be, to the majority, unless government aid be obtained to support the pupils through a longer term of study, provide a much increased staff of teachers, and uphold a highly expensive boarding-out system. Neither are we convinced that results will repay this greater expenditure. The voices spoken of as "not euphonious" are in reality so harsh and unnatural that teachers of articulating schools confess themselves unable to bear that distressing wear and tear produced by constant association with their pupils. It is, no doubt, a great advantage for the deaf to be able to converse with hearing persons, and those who do acquire this power will most readily find employment. Still, what a man is and has in himself is of more consequence than all his surroundings; and we must remember that only a minority of the deaf can attain to an adequate grasp of language by this means.

The system has received a "full" trial on the continent, with what result the following extract will show. Dr. Gallaudet, President of the Deaf Mute College, Washington, was in 1867 appointed to examine into methods and results, and to report on the state of education in Europe, with the view of adopting what was best for the deaf and dumb. In the course of a most exhaustive inquiry, he visited fourteen of the countries of Europe and forty-four of the principal institutions. He sums up the whole case as follows.

"Nowhere have my own examinations exhibited results sustaining the idea that 50 per cent. of the deaf and dumb can acquire a sufficient fluency in articulation to converse readily with strangers. That from 10 to 20 per cent. can do this, I have no manner of doubt. An additional 40 per cent. may aspire to converse on commonplace subjects with their teachers, family, and intimate friends. But oral language cannot, in the fullest sense of the term, be mastered by a majority of deaf mutes. Its proper position, therefore, in the system of instruction is not as a base or foundation, nor yet as the principal material in the superstructure, but rather as an adornment to certain portions of the building."

It must also be borne in mind that, except in very rare instances, persons accustomed to lip-reading are unable to follow a lecture or sermon, and that they cannot enter into a conversation between two or more persons. I am, etc., TRUTH.

\*\* In the article referred to, for "a few minutes," read in the last line "a few months."

## OBITUARY.

### WILLIAM DANIEL MOORE, M.D., M.R.I.A., DUBLIN.

WILLIAM DANIEL MOORE was born in April 1813 in Dublin, where his father and grandfather had long practised medicine and pharmacy. His father having died when he was very young, he was in 1826 apprenticed to his grandfather, and afterwards to Dr. Johnson, then Professor of Midwifery in the Royal College of Surgeons of Ireland. In 1828, he entered the University of Dublin for a time; but interrupted his university course, and did not resume it until 1840. In May 1833, he became a licentiate of the Apothecaries' Hall of Ireland; and in the following year, a licentiate of the Royal College of Surgeons of Edinburgh. He graduated as A.B. and M.B. of the University of Dublin in 1843, and as M.D. in 1860. In 1837, he became one of the Examiners of the Apothecaries' Hall, and retained the post twenty-three years, being governor in 1843-44. In 1867, he became a licentiate of the King and Queen's College of Physicians. He was admitted to the *ad eundem* degree of M.D. of Oxford in 1862, and to that of Cambridge in 1866.

Dr. Moore was distinguished for his literary abilities, and especially for his knowledge of European languages, which enabled him to make numerous valuable contributions to English and Irish medical literature in the form of translations of articles from the Dutch and Scandinavian languages. He was a constant contributor to the *Dublin Quarterly Journal of Medical Science* during the twelve years (1850-1861) in which the late Dr. Neligan was the editor of that periodical. His translations and reviews extended to books in the French, Italian, Spanish, German, Swedish, Danish, Dutch, and Latin languages, and were continued at times for several years, while his health permitted.

Among his original contributions were papers on the following subjects: "A Peculiar Corrosion of Lead in Pipes from Galvanic Action Developed by the Contact of Organic Matter," read before the Chemical Section of the British Association in 1835; a "Statistical View of the Principal Medicines prescribed in Dublin during the last Sixty Years" (*Dublin Journal of Medical Science*, 1836); "Outline of the History of

Pharmacy in Ireland"; Researches on the Coagulability of Human Milk; the Latent Period of Scarlatina; the Urine of the Crocodile; Unilateral Atrophy of the Face; etc. These were published in the *Dublin Quarterly Journal*; besides which, he contributed various papers to other medical periodicals.

In 1855, he translated, from the Norwegian of Dahl, Heller's *Pathological Chemistry of the Urine*. He also translated for the New Sydenham Society the late Dr. Schroeder van der Kolk's essays on the Spinal Cord and on the Medulla Oblongata, and on Atrophy of the Brain; and also the great work of Donders of Utrecht *On the Anomalies of Accommodation and Refraction of the Eye*.

Dr. Moore's labours in making Scandinavian medical literature known in this country led to his being elected a Fellow of the Swedish Society of Physicians, of the Norwegian Medical Society, and of the Royal Medical Society of Copenhagen.

About the beginning of 1867, the first symptoms of the disease which ultimately caused his death—progressive muscular atrophy—manifested themselves. Slowly he lost strength; and in the beginning of 1870, he ceased to be able to walk. From the end of May of that year, he never left the house, except on one or two occasions when he was carried into the garden for a short time. About three weeks ago, his little remaining strength began to give way more rapidly, and on the night of Saturday, October 28th, he entered calmly and peacefully into rest. To the end, his intellect was clear and vigorous as ever.

### DAVID BOWEN, M.R.C.S.ENG.

MR. DAVID BOWEN died at Newport, Pembrokeshire, on October 22nd, of hydrothorax. He had been ailing for some months; but on the 17th, three days before his death, he drove a distance of six miles to vaccinate. He also went out a little way in his gig the next day. On the morning of Sunday, the 22nd, he prescribed for a patient, and then, after a terrible struggle with his complaint, calmly breathed his last a quarter before midnight. He was much beloved and respected for his great tenderness of heart, his truthfulness and integrity, and was trusted in for his professional skill.

### EVAN CAMERON, M.D.

A YOUNG practitioner of high attainments and bright promise has been suddenly taken from among us. After a distinguished career at Glasgow University, Dr. Cameron practised with much success in Bradford (in connection with Dr. Burnie of that town), and had earned for himself by his winning manners and devoted attention to the duties of his profession, the love and esteem of all who came in contact with him. He bade fair to take a high place among his professional brethren had life been granted him. But he has been taken away in early manhood, and numerous friends now mourn his loss.

In the midst of health and a busy life he was struck down with fever, from which he was slowly recovering, when he went to Newabbey, near Dumfries, to recruit, but a relapse occurred which ended fatally on September 30th.

### EDWARD NEWBOLD, M.R.C.S., OF MACCLESFIELD.

EDWARD NEWBOLD, whose death took place at Worthing on September 8th, was born at Macclesfield in 1811, being the sixth son of Mr. Francis Newbold, a surgeon. As a student, Mr. Newbold first resided at Manchester with Mr. Thorpe; at whose death he was transferred to Mr. Turner. During his residence with the latter gentleman, he was a diligent student at the School of Medicine and the Royal Manchester Infirmary, and gained some honorary prizes. He also studied in London under Sir Astley Cooper and Lawrence. After passing his examinations, he joined for some time in partnership a medical practitioner at Aldborough and Hawkshurst. At the death of his father, Mr. E. Newbold returned to Macclesfield. He there enjoyed for many years a large private practice. More than twenty years he was honorary surgeon to the Dispensary; he was also surgeon to the Union districts, comprising five populous townships; surgeon to several insurance societies, and medical inspector of factories, holding the latter appointment up to the time of his death. Mr. Newbold was well-informed in his profession, and lived a most laborious life; indeed, had he allowed himself that periodical relaxation which is needful to all hard-workers, the insidious disease, which was gradually taking root—apparently without his knowledge—might have been staved off. Last winter symptoms shewed themselves, which caused him to take a physician's advice. Entire rest was ordered, and he retired to Worthing, where, after severe suffering, relieved at times only to give renewed hope that his great natural strength would prevail against the deeply seated malady, he succumbed, to the great regret of his numerous patients, friends, and surviving relatives.

## OSMER KING, F.R.C.S.ENG., GREENWICH.

It is with regret that we have this week to announce the death of this much respected practitioner. Mr. King was descended from an old and respectable family in Surrey. Having chosen the profession of medicine, he entered as a student at Guy's Hospital, and became a Member of the Royal College of Surgeons in 1839, and an Honorary Fellow in 1859. Soon after passing his medical examinations, he commenced practice near Russell Square, and rapidly met with much success. In 1848, he joined as a junior partner the old established firm of Sutton and Sams at Greenwich and Blackheath, and soon became deservedly popular. He afterwards carried on for many years one of the leading practices in the county of Kent. For the last few years, heavy domestic trials and the responsibility and anxiety of his professional work seemed to be fast telling upon his failing health; and two years ago he chose as his junior partner Dr. Ralph Gooding of Blackheath. From this time he became gradually more feeble, and three weeks ago took cold, which was rapidly succeeded by congestion of the lungs, from which he died on October 24th, at Eccleshall in Staffordshire, whither he had retired some months before. His genial smile and kindly manner, his earnest sympathy in the hour of trial and bereavement, and his almost religious devotion to the duties of his profession, can hardly be forgotten during the lifetime of many of his patients; and all must feel that they have lost not only their medical adviser, but also a true friend. Beloved by all who knew him, and always looked up to as an English gentleman and able practitioner, he has departed at the early age of 54, leaving a widow and one son. He was interred in the family grave at Nunhead, on Monday, October 30th.

## UNIVERSITY INTELLIGENCE.

## UNIVERSITY OF CAMBRIDGE.

**THE DEGREE OF B.M.**—The Board of Medical Studies has recommended that the following be added to the requirements prior to the third examination for the degree of Bachelor of Medicine:—"That the candidate be required to produce a certificate of having been clinical clerk for six months at least at a recognised hospital; or of having, subsequently to the completion of his attendance on hospital practice, attended to practical medicine with special charge of patients in a hospital, dispensary, or parochial union, under superintendence of a qualified practitioner, unless he himself be duly qualified. This regulation to come into force in the Easter Term, 1872; and that 'Experimental Physics' be added to the list of courses of lectures in Section 10 of Regulations for Degrees in Medicine."

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen passed their primary examinations in anatomy and physiology, at a meeting of the Court of Examiners, on Nov. 8th; and, when eligible, will be admitted to the pass examination.

Mosses, Henry French Banham, B.A.Cantab., Thomas H. Haslam, H. Selve Bennett, Chas. W. Owen, and Alexander J. Allott (Students of St. Thomas's Hospital); G. Boulton Elliott, W. Allan May, and Adolphus Bevan (of Guy's Hospital); Chas. F. Hutchinson and Frederick J. Sawdon (of the Edinburgh School); Chas. W. Harvey and Ebenezer J. Ramsay (of University College); C. Aylife Lloyd and A. Somers Ivens (of St. Bartholomew's Hospital); Alexander Harbison and Ebenezer E. Sloane (of the Belfast School); Charles E. Piers (of the Dublin School); John C. Brady (of the Charing Cross Hospital); W. Graham Ross (of the Montreal School); James Magill, M.D. Queen's University, Ireland (of the Cork School); James Taylor Hyatt (of the Westminster School); Lawrence W. Spencer (of King's College); and A. Cockburn Collinson (of St. Mary's Hospital).

Ten candidates having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their anatomical and physiological studies for three months.—The pass examination for the diploma of member will commence this day (Friday), and be continued throughout the ensuing week, owing to the large number of candidates.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, November 2nd, 1871.

Batell, Alfred, Polton, Shepton Mallet  
Davies, Arthur Evelyn, Beacon House, near Newbridge  
Lang, John Messier, Uxbridge, Berks.  
Thompson, Henry, Hull

The following gentlemen also on the same day passed their first professional examination.

Emms, Alfred Wilson, Guy's Hospital  
Kenyon, George Simpson, Liverpool School of Medicine  
Townend, Joseph Henry, Guy's Hospital

## MEDICAL VACANCIES.

**THE following vacancies are announced:—**

CARRICKMACROSS UNION, co. Monaghan—Medical Officer for the Raferagh Dispensary District: £80 per annum, and Registration and Vaccination Fees.  
CHORLTON UNION, Lancashire—Assistant Medical Officer for the Workhouse at Withington: £120 per annum, and residence.  
DERBYSHIRE LUNATIC ASYLUM, Mickleover—Superintendent-Physician: £400 per annum, lodgings and rations.  
ENNISCORTHY UNION, co. Wexford—Medical Officer for the Oulart Dispensary District.  
GENERAL HOSPITAL, Birmingham—House-Governor and Secretary.  
HIGHWORTH and SWINDON UNION, Wilts—Medical Officer for District No. 3: £57:10 per annum.  
INFIRMARY FOR CONSUMPTION, &c., Margaret Street, Cavendish Square—Visiting Physician.  
KENT and CANTERBURY HOSPITAL—House Surgeon: £80 per annum, board, lodging, and washing.  
LINCOLNSHIRE—Medical Officer for the County Gaol for the parts of Lindsey: £120 per annum.  
LIVERPOOL ROYAL INFIRMARY—Physician.  
NORTH MAYNE and DELTING, Shetland, Parishes of—Medical Officer.  
REETH UNION, Yorkshire—Medical Officer for the Muker District: £22:10:0 per annum, and extra fees.  
ROYAL FREE HOSPITAL—Junior House-Surgeon.  
ROYAL INFIRMARY, Edinburgh—General Superintendent: £420 per annum, and house rent.  
ST. MARYLEBONE, Parish of—Medical Officer for St. Mary's Registration District: £100 per annum.  
ST. THOMAS'S HOSPITAL—Two Dispensers: £100 and £80 per annum.  
SHEFFIELD PUBLIC HOSPITAL and DISPENSARY—Assistant House-Surgeon: £65 per annum, apartments, washing, and board.  
SOUTH STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton—Physician's Assistant: £100 per ann., with board, washing, and furnished apartments.  
STRATHKINNESS, by St. Andrew's—Medical Officer.  
SUSSEX COUNTY HOSPITAL, Brighton—Surgeon; Assistant-Surgeon.  
TEIGNMOUTH, DAWLISH, and NEWTON DISPENSARY and INFIRMARY—House-Surgeon: £50 per annum, and board and lodging.  
TOXTETH PARK TOWNSHIP—Assistant Medical Officer at the Workhouse: £100 per annum, and allowances.  
VICTORIA HOSPITAL FOR SICK CHILDREN, Chelsea—House-Surgeon.  
YORK—Visiting Physician to the Retreat, the Lawrence House, and the Terrace House Lunatic Asylums.  
YORK PENITENTIARY—Visiting Physician.

## MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.*

\*ANDERSON, J. Ford, M.D., appointed Medical Officer to the Postmen for the Hampstead Division of the Post Office, comprising also the Kilburn District.  
BRODIE, Edward Fitzgerald, L.K.Q.C.P.Irel., appointed Medical Officer, etc., for the Lawrencetown Dispensary District of the Ballinasloe Union, co. Galway, *vice* John Barton, M.B., resigned.  
CLIBBORN, Cuthbert John, M.B., appointed Medical Officer, etc., for the Kilbegan Dispensary District of the Balinglass Union, co. Wicklow, *vice* Robert Dockeryan, L.R.C.S.Irel., deceased.  
\*FLOWER, Thomas, Esq., appointed Medical Officer and Public Vaccinator for the Warminster District Union Workhouse and Corsley District of the Warminster Union, *vice* P. Grubb, Esq., resigned.  
FROST, Dr. E. W., appointed Medical Officer for the Newmarket-on-Fergus Dispensary District of the Ennis Union, *vice* D. Courtenay, L.R.C.S.Irel., resigned.

## BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.*

## DEATH.

PHILLIPS, Edward, Esq., Surgeon, at Bermondsey Street, aged 41, on Oct. 22nd.

**PROSECUTION UNDER THE MEDICAL ACT.**—A person of the name of J. H. Boyd, who called himself "professor", and advertised himself illegally as a medical practitioner, has, at the instance of a chemist, been fined by Sheriff Comrie Thomson, of Aberdeen, £10 in absence, with £2:2 expenses, or forty days imprisonment.

**BEQUESTS, DONATIONS, ETC.**—Miss M. M. H. Davies, of Brompton Square, has bequeathed to the Gloucester County Infirmary, and to the Gloucester Lunatic Asylum, £10,000, three per cent. reduced annuities, each.—The Rev. G. A. Gratwicke, D.D., late Master of Emmanuel College, Oxford, and Canon of Norwich, has bequeathed £100 each to Addenbrooke's Hospital, Cambridge, and the Commissioners for the Sick Poor for Norwich.—Mr. W. J. Myers, of Seaforth, has bequeathed £50 each to the Northern Hospital, Liverpool, and the Hospital for Consumption, etc., Liverpool, and a share of the "residue" to the Liverpool Royal Infirmary.—Mr. J. Pearson has given £100 towards the Chapel Fund of the National Hospital for Consumption, Ventnor.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY** .....Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**TUESDAY** .....Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**WEDNESDAY**..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**THURSDAY**...St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**FRIDAY**.....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.

**SATURDAY**...St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY**.—Medical Society of London, 8 P.M. Dr. Sansom, "A Case of Endocarditis complicating Phthisis"; Dr. Alfred Carpenter, "Two Cases of Muscular Anesthesia, with Remarks."

**TUESDAY**.—Royal Medical and Chirurgical Society, 8.30 P.M. Mr. A. Durham, "On the Operation of Opening the Larynx by Section of the Cartilages for the Removal of Growths and Foreign Bodies."

**THURSDAY**.—Harveian Society of London, 8 P.M. Mr. Berkeley Hill, "Treatment of Surgical Inflammation by Counterirritation."

## NOTICES TO CORRESPONDENTS.

**ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.**

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**TO PURCHASERS**.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with *halfpenny* stamps for the amount.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

**A CONSTANT READER AND SUBSCRIBER**.—The list of vacancies in the JOURNAL is, we believe, more complete than any other which is published. We shall be happy, however, to receive suggestions on the subject.

## HYPODERMIC INJECTION OF MERCURY.

**SIR**.—Can you inform your readers how many drops of the solution of corrosive sublimate were used by Dr. Sigmund in his treatment of syphilis by the hypodermic injection of mercury? In your notice of this subject in the JOURNAL of October 21st (p. 470), the strength of the solution is given, but not the quantity used for each injection.

I am, etc., SYPHILIS.

\* Dr. Sigmund does not state, in the paper from which the article in the JOURNAL was derived, how much was injected on each occasion. From a previous reference, however, to Dr. Sigmund's experiments with subcutaneous injection of mercury, we learn that the quantity varied from ten to fifteen minims—usually being fifteen minims.

## ACTION OF CHLORAL ON THE FŒTUS IN UTERO.

**SIR**.—I have a patient who, having had six premature labours at the seventh month, and six dead children, has just been delivered at the full time of a living child. To this patient, for three days before her confinement, thirty grains of chloral were administered every four hours with scarce one intermission. The chloral certainly did not kill the child in this instance; though, it must be admitted, the case would be a bad one for its administration, if the drug really had any effect for evil on the unborn child.

I am, etc.,

Newport, Isle of Wight, November 1871.

GEORGE DABBS, M.D.

**SIR**.—In answer to an Associate, I can offer one case in which I prescribed half-drachm doses every two hours to Mrs. B., aged 24, eight months gone in her fourth pregnancy. She had her usual symptoms of miscarriage, having never been delivered of a child which lived more than twenty-four hours. After four doses, all pains left her. Since then, she has been delivered of a living child (small), now five weeks old, and apparently healthy. I may add, that five grains of camphor in emulsion did not stay the pains.

I am, etc.,

November 1871.

F. T. L. T.

**DR. ROBERTSON (Glasgow)**.—Next week.

## MEDICAL ETIQUETTE.

We referred recently to a grievance of Dr. Royston against Mr. Delamark Freeman. Mr. Freeman offers now, in a very long communication, various explanations which are to our mind by no means satisfactory. It is a first principle in professional conduct, that patients of a medical brother, whose confidence is acquired while in charge of his practice, are handed back to him.

**NOTICE TO ADVERTISERS**.—Advertisements should be forwarded direct to the Printing-Office, 37, Great Queen Street, W.C., addressed to Mr. F. H. HEATHCOTE, not later than *Thursday*, twelve o'clock.

**MR. WALTER WHITE** (Chew Magna) will find a full report of the meeting in the *Temperance Record* for November 4th (Tweedie, 337, Strand).

## PROFESSIONAL ETIQUETTE.

As the result of a perusal of the correspondence which Mr. Wright of Derby has forwarded to us, we have come to the conclusion that, however just his intentions, he did not display proper courtesy to Mr. Iliffe. Mrs. Tunley's proposition is, that Mr. Wright should see the patient in consultation with Mr. Iliffe; and that is the course which, under the circumstances, we think it would have been proper to adopt. We are not surprised that Mr. Iliffe should feel hurt.

## TEACHING OF THE DEAF AND DUMB.

**SIR**.—In a leading article in the JOURNAL for November 4th, on the Education of the Deaf and Dumb by Lip-reading and Articulation, the concluding sentence is as follows:—"It ought also to be made known that persons who have become deaf after they have talked naturally, may at any age be taught to converse by this method in a few minutes." Such a statement is probably a clerical error, but none the less likely to throw discredit on the system. As the author of the paper you notice, I trust you will allow me space to correct this, and to say that children who have talked naturally, and have become incurably deaf, can be taken in hand at once, with a few months' instruction be prevented from becoming dumb, by teaching them to read from the lips; that adults who are very deaf may be taught lip-reading, and that children who have once spoken and, in consequence of extreme deafness, have become dumb, may be more easily taught than those children who have never heard.

I am, etc., W. B. DALBY.

Grosvenor Street, November 1871.

**DR. E. S. THOMPSON**.—The subject shall receive early attention.

## LEARNING FOR GUARDIANS.

A GUARDIAN of the Dudley Union has been afflicted by observing that guardians and their officers suffer from defects of education, which prevent them from correctly pronouncing or interpreting the names of the diseases to which paupers are liable, and which are catalogued in the returns and certificates of the Poor-law medical officers. To remedy this, he has prepared a Pronouncing Dictionary, of which the prospectus lies before us. It is so full of *naïveté*, that it is worth transcribing.

"All the medical officers of the various Poor-law Unions in the United Kingdom, in giving certificates of the cause of illness of the persons applying for parochial relief, write the name of the disease in Latin, which very often puzzles both the Guardians and their officers: and the writer has known the question run round the Board-room to know what complaint or disease the applicant is suffering from. Besides, very few officers are able to give a correct pronunciation of the medical terms, even after years of practice in their calling."

"To remedy the above, and thereby place the Guardians and their officers on a par with the medical gentlemen of the various Poor-law Unions, is the object the writer has in view in issuing his Pronouncing Dictionary."

## "Specimen of the Work."

ABERRATION, ab-er-á-shun. Partial insanity.  
ACATHARSIA, a-ka-thár'she-a. Impurity of the blood.  
ALBUGO, al-bú-go. A disease of the eye.  
ANASARCA, an-a-sár'-ka. A dropsical disease.  
ANTHRAX, an'-thracks. A carbuncle.  
APESIA, ap-ep'-sin. Defective digestion. See Dyspepsia and Indigestion.  
ARTHRODYNIA, ár-thro-dín'-e-a. Chronic rheumatism.  
ASAPHIA, as-á-fia. A defect of voice.  
ASCITES, as-si'-tes. Dropsy of the belly."

PONTYPRIDD need only apply to the Honorary Secretaries of the Branch covering the district to which he moves.

## DEATH-CERTIFICATES.

**SIR**.—It was only the other day that my attention was drawn to some editorial comments in your paper upon a case in which I had given a death-certificate without having been in attendance upon the patient, or, indeed, having seen him for six months prior to his decease. May I be permitted, though somewhat late in the day, to offer a few remarks upon this case, as I am inclined to think that a fuller acquaintance with the facts will lead you to soften the severity of your strictures?

In your remarks upon the case, you state that Dr. Haddon had attended the man prior to death, and that he was of opinion that death resulted from pyonephrosis; whereas I, who had not seen him for six months, stated that he died of heart-disease. This statement, sir, is incorrect. Dr. Haddon never saw the man alive, and, consequently, was no better able to judge of the cause of death than I was. Arriving when life was extinct, he volunteered the statement, however, that the man had died of heart-disease; he did not state at the time, or at the inquest, that he attributed the death to pyonephrosis; nor can I comprehend when he arrived at this conclusion, or whence you gathered such an idea without involving Dr. Haddon as your informant.

My excuse for granting the certificate is briefly this. I had attended the deceased, and known his family for many years. The poor man suffered from valvular disease of the heart; and it was solely to save him expense that I did not continue my visits up to the date of his death. I heard, from time to time, of his failing health, and was of course prepared to hear any day that he had suddenly expired. This news was at length brought to me, when I did not hesitate to give a certificate of death, as I had been in constant receipt of information as to the man's sinking condition. An inquest was held, for some reason or other, at which, as you correctly state, the coroner, Mr. Price, reflected upon my conduct for granting the certificate; but when I inform you, sir, that no *post mortem* examination was ordered, you will, I think, agree with me in doubting whether Mr. Price or Mr. Haddon, or both together, were better able to arrive at a correct diagnosis than myself, who had been intimately acquainted with the man's history for many years. Under the circumstances, I cannot but regard the use which has been made of this case to exalt Dr. Haddon at my expense, as both illiberal and unjust.

Eccles, November 17, 1871.

I am, etc., RICHARD ROE.

P.S.—Possibly it may strike an ordinary observer as somewhat singular that Dr. Haddon should write to you in London in preference to communicating with me if he should feel himself aggrieved, seeing that we are living almost a stone-throw from one another.

**NOTICES of Births, Marriages, Deaths, and Appointments, intended for insertion in the JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.**

SIR.—Can any of your readers who are Poor-law medical officers inform me whether I am entitled as such an one to charge the extra fee allowed for midwifery cases in my parish when the same attendance is required in cases of miscarriage (under six months)? I am, etc.,  
CUIQUE JUSTITIA.  
London, November 1871.

**EARLY PREGNANCY.**  
SIR.—Under the head of Obstetric Memoranda, in the JOURNAL of October 28th, is a case of early pregnancy by Dr. Haining. In the churchyard of Rock, near here, was a gravestone with these verses,

"Ten years I was a maid,  
One year I was a wife,  
One day I was a mother,  
And then I lost my life."

I was apprenticed here in 1795, where I have been ever since, with the exception of five years in London: and during the course of this long practice, I have attended three parturient mothers under 13 years of age. The mothers and children all did well. I am, etc.,  
THOMAS POPE.  
Clebury Mortimer, November 4th, 1871.

#### MEDICAL CO-OPERATION.

SIR.—I beg to call your attention to the enclosed copy of a circular, which has been recently distributed in this neighbourhood, and which, as you will see, sets forth that a "Society" has been formed, with the object of providing first-rate medical attendance and medicine for on annual payment of ten shillings. The subscriptions are received quarterly or half-yearly, in advance, at the residence of Mr. Delamark Freeman, 20, Talbot Road, whose name, with that of a Secretary alone, appears on the prospectus. By what is, perhaps, merely a coincidence, a man has been engaged during the past few weeks calling upon the residents, including many of my patients, and soliciting them, in the most importunate manner, and much to their annoyance in many instances, to become members of this Society. When taxed with being an agent of Mr. Freeman's, he answered that he was performing his laborious task with purely benevolent motives; that a relative of his had long suffered from a dreadful malady, which, having defied the efforts of all the medical men in Bayswater, was cured with marvellous rapidity by Mr. Freeman; and that he was, therefore, anxious that every sufferer should avail himself of Mr. Freeman's extraordinary skill, more especially since they could do so for the ridiculously small sum of ten shillings a-year, not to speak of the medicine included. Now, sir, in the advertising columns of the papers, we read daily of cases in which wonderful cures have been wrought by means of a single box of pills or ointment; and, as we, of course, believe these to be true, we do not doubt that Mr. Freeman's case may be also authentic; but I, and many of my confrères in this district for whom I speak, deny that this case had been previously treated by us; and we deny, therefore, at least, that it had defied the efforts of all the medical men in Bayswater. Seriously, we think we have a right to demand from Mr. Freeman some account of the constitution of this "society" to which he is urging, and we should also be glad, at the same time, to hear whether the touting to which I have alluded has been carried on with his consent, and, if not, whether he has requested his officious friend to desist from so equivocal a mode of displaying his gratitude.

If Mr. Freeman can give us satisfactory explanations on these points, and if he can clear himself from the grave charges of professional misconduct which Dr. Royston brings against him, I am sure he will receive from the neighbouring practitioners a welcome such as is never refused to new comers in Bayswater. When these conditions are those of professional men and gentlemen. I am, etc.,  
112, Westbourne Grove, Bayswater, W. ALGERNON C. W. NORTON.

(COPY.)

"Bayswater Mutual Medical Aid Society, for securing professional medical and surgical attendance, and the supply of all medicines to the subscribers.—This Society is formed to enable persons, by payment of a small sum, to secure themselves efficient medical and surgical aid in case of illness or accident. All persons residing within the area of three miles of the 'Royal Oak', Bayswater, can become members of this Society. It is not intended that persons who may be suffering from any chronic or inveterate disorder shall participate in the advantages of this Society. Terms of subscription, ten shillings per annum, payable quarterly or half-yearly in advance. Hon. Sec., H. Harris, Esq., Surgeon, Delamark Freeman, 20, Talbot Road, Bayswater, W. Subscriptions will be received between the hours of ten and eleven o'clock in the morning, and from seven to eight in the evening, at 20, Talbot Road.

#### A GREAT MISTAKE IN PREVENTING WASTE OF WATER.

SIR.—In your report of my paper on the prevention of the waste of water by the very simple expedient of providing every house with a limited but liberal supply, you mention two objections that would not, I think, have been urged if I had not been pressed for time when explaining the plan.

Mr. Renshaw objected, because he said water must be supplied in abundance. This is quite true, it should be, and would by any plan be supplied in ample abundance, as much as will be used; it is not abundance, but extravagance, to supply more than is used.

Mr. Charles's thought respecting the storage of water liable to objection on account of the water being so fresh in the tank. But he did not mention this objection, as, simply in the large proportion of the water which I proposed, to supply to each house, and as all right in the pipes themselves, which no one can suppose to be of water, and in which the water can easily be kept as cool as is desirable by communicating from the outside surface, it kept cool.

I thought it unnecessary to mention such a well-known objection. Other objections may be proposed by experiments on simple. "Practical men" will, of course, object to a change, because it is better to believe anything to be practicable unless it is done, and when it is done they say they know it from the fact. For example, one of them had claimed that the little hole proposed to limit the supply to the need of water would not discharge regularly at the pressure would vary; also, that it would very soon be stopped up. There is no objection to the flow being regulated by a little valve or stopcock than the water, provided the quantity per diem is enough, and if the water be filtered, so it ought to be, it will be free for the regulating hole to be obstructed; and if the water be not filtered, it may be as easily filtered before as after it passes the regulating hole; and unless the water be very dirty, it will be a long time before the filter becomes clogged.

I am, etc., P. H. HOLLAND, Medical Inspector.

DR. BROWN (Berwick-on-Tweed).—To the General Secretary, 13, Newhall Street, Birmingham. Dr. Brown should have, and no doubt has, received four circulars asking for his subscriptions, but has probably overlooked them.

#### EXTRACTS FROM A DOCTOR'S DIARY.

I.—On a raw October afternoon, thousands assembled at Blackheath to see, hear, and criticise Mr. Gladstone. Cases of bronchitis, jaundice, and puerperal mania, required attention; but the occasion of delay was exceptionally excusable. From a distance, the scene on the hustings reminded us of executions at the Old Bailey, and the last act of a well known drama, when Calcraft, explaining to Punch the simple arrangement of the noose and gibbet, is immediately strangled, and added to other victims of the fatal club, including Judy, the beadle, and the family medical attendant. On horseback, behind the crowd, in spite of the distance, the cheers, occasional groans and interruptions, above all, now and then, we could catch a few sentences, flowing in fascinating cadence, beautiful in composition, powerful in argument. Through an opera-glass, we notice a deadly pale, earnest face, marked with lines in all directions; a splendid head, uncovered, exposed to the cold for two hours, whilst we are shivering with our hats on; a waistcoat cut low, the chest unprotected. When we considered that the Premier next month will be 62 years of age, the work he has undergone, and the responsibilities of office, it is most extraordinary to estimate the talent, the intellect, the memory, and the physical endurance displayed. We have not read the speech yet; but from those who had good places near, the information is received that Mr. Gladstone never hesitated for an instant, required only statistical references, and his voice at the end remained firm and clear.

II.—Quite recently, a very interesting dinner-party took place at mess. After witnessing the Autumn Manœuvres, the representatives of the foreign governments sat temporarily harmonious at the festive board. One feels inclined to describe the appearance of Russian, Prussian, French, and Portuguese; what the American said, what the Turk did, and how every one paid the greatest deference to Mr. Russell; but, no, excepting Blumenthal. The turtle soup was not allowed to cool, the Roman punch to go untasted, nor the venison lost sight of. All the time attention became riveted on a quiet, slim, gentlemanly man (dressed in plain clothes—the others in uniform), who had played a prominent part in the late war. What could have been passing through his mind, as ever and anon he cast admiring glances at the silver candelabra, the splendid plate, and the bright spoons? *A Berlin!* perhaps. Anyhow, Sedan was somewhat avenged, for the great general drunk the patent head-splitting brown sherry—that morning wine. The port is good, the claret still better, and we silently drank "Vive l'Empereur!" "Vive l'Imperatrice!" "Vive le Prince Impérial!" may they soon hold their own again, and, like John Gilpin, may we be there to see.

III.—Soapy Sponge never travels without Moggs' Cab Fares: we generally sleep with the Registrar-General's Annual under the pillow. From one of the letters that Dr. Farr, *à la Toots*, is in the habit of writing to himself, we learn that gout is becoming more fatal, for the deaths of 351 men and 96 women are recorded; also that "women have hitherto, and we hope will continue to set men good example"; we thought it was the other way, and, like the Turk, whenever there is a row, we inquire who is the lady. The Lord Mayor is requested to take notice that "refined gluttony is as fatal as intoxicating drink." Regarding the symptoms and treatment of gout, consult Garrod and Fuller, or, better still, Mr. Weller, senior, who recommends gin to many a widow with a good loud voice, and a decent notion of using it, as an infallible prescription. Pray accept the assurances of our distinguished consideration, etc.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Shrewsbury Chronicle, Nov. 3rd; The Liverpool Albion, Nov. 6th; The Woolwich Gazette and Greenwich and Deptford Chronicle, Nov. 4th; The Morpeth Chronicle; The Irish Times; The Melbourne Argus; The New York Tribune; etc.

#### COMMUNICATIONS, LETTERS, &c., have been received from:—

Dr. Robt. Barnes, London; Dr. J. Matthews Duncan, Edinburgh; Dr. J. Braxton Hicks, London; Dr. R. Liveing, London; Mr. Teevan, London; Dr. T. Clifford Allbutt, Leeds; Dr. Hitchman, Mickleover; Dr. R. Hibbert Taylor, Liverpool; Dr. Swayne, Bristol; Mr. Prichard, Bristol; Mr. Crossman, Hambrook; Mr. C. Gold, London; Mr. Gardner, Forfar; Dr. G. Hill, Hooton; Mr. A. H. Dolman, Derby; Mr. G. S. Elliston, Ipswich; Mr. Fowler, Bath; Mr. Jebb, London; Pendennis, Leicester; Mr. D. H. Watson, Stockton-on-Tees; Dr. H. Gueneau de Mussy, Paris; Mr. Barnard, London; Dr. J. C. Reid, Newbiggin-by-Sea; The Registrar-General of England; The Secretary of Apothecaries' Hall; The Registrar-General of Ireland; Mr. T. M. ## MEMORABILIA

IN THE

## HISTORY OF THE BRITISH MEDICAL ASSOCIATION.

*Being part of an Address delivered at the Annual Meeting of the Reading Branch.*

BY GEORGE MAY, JUN., ESQ.,

President of the Branch; Surgeon to the Royal Berkshire Hospital; etc.

THE question has often been put to me, Why should I join the Association? What good has it ever done? I propose to devote the time at our disposal to a brief review of what the Association has done for the public and for the profession.

The Provincial Medical and Surgical Association was founded by Dr. Hastings at a meeting of fifty medical men in the Board Room of the Infirmary at Worcester in July 1832. It consisted of 150 members; increased before the end of the year to 310. It was not formed in imitation of the British Association for the Advancement of Science, which had been established the previous year, but arose from the success of the *Midland Medical and Surgical Reporter*. Its objects were—

1. *Social*.—To promote friendly intercourse at the annual meetings.
2. *Ethical*.—To check the spirit of misrule and confusion which actuated the profession, by the influence of public opinion, and by establishing harmony and good feeling.
3. *Scientific*.—To develop the science of medicine by collecting the results of individual experience.

The managing body consisted of a President and a Council, to represent districts, to collect subscriptions, and to decide on the essays to be published.

Before attempting to trace the results due to the Association, it may be useful to regard for a moment the condition of the medical profession at the time of which we speak. Medicine may be regarded as a science, an art, or a trade. The time was long past when Dr. Sangrado could treat his patients with copious draughts of warm water, and call in the barber-surgeon to finish his work by free venesection; or when Gil Blas could give his client the exclusive right to poison his Majesty's subjects by the sale of drugs; or when, in our own country, Dr. Reid was allowed to erect a stage for the sale of drugs, the surgeon in addition being allowed to use music, but both being wisely ordered not to hinder people from coming to the pump. But at this time medicine was something between a trade and an art. Regarded as a mere trade, the practice of physic required but little skill, the qualities best suited for insuring a prosperous career having no necessary connexion with intellect or science. An imposing manner, confident pretension, verbose declamation interlarded with high sounding terms, however unintelligible or unmeaning, unhesitating assurance of cure, condemnation of whatever antecedent practitioners had done—these and various still less worthy arts will suffice to gain a reputation sufficient to satisfy the cupidity of whoever can descend so low as to resort to them. Swift laments—

"Deprived of kind Arbuthnot's aid,  
Who knew his art, but not his trade."

I have recently become possessed of a medical account of this period, in which one shilling is charged for barley and gum, and have seen another sent by a gentleman, once known to most of you, in which sixpence was charged for an oily mixture.

From this condition the profession was just emerging when the Association was founded; and it is curious to notice how completely its founders overlooked the great influence it was destined to exert on what may be called the political aspects of medicine. The first trace of any such action occurred in 1833, when a letter was sent by the Association to Parliament thanking Government for the determination to record the causes of death. In 1835, the Eastern Counties Association was formed, "to watch over the interests of the profession", and from this time we shall be able to trace the efforts of two distinct and often opposing parties in the Association. But for our present purpose it will be more convenient to take an historical view, only tracing any one subject to its conclusion, where it can easily be so dealt with.

1833. *Bristol*.—The annual meeting was noted for its recommendation that joint reports should be made on subjects of medical interest. Hitherto this has not attracted the attention it deserves, chiefly from want of financial support; but it has probably a great future before it. Correspondents were elected to report on the medicine of foreign countries—a field yet unworked by this Association. The offer of a prize

for an essay called forth several valuable contributions. Medical reform was foreshadowed in the following truthful description of the President. "By a forced and unnatural division of offices, the profession has been split into departments. Each department has had assigned to it a separate superintendence, the aim of which has been to advance its interests without reference to the other branches. Government of the profession by separate and independent corporations has been fully tried and utterly failed. We may patiently wait those salutary reforms in medical polity which, sooner or later, an enlightened legislature must accord."

1834. *Birmingham*.—Members residing in large towns were advised to meet for mutual improvement. This was the first indication of the formation of branches, which have since contributed so largely to the success of the Association.

Provident dispensaries were recommended. This subject has recently received special attention; but, although many flourishing dispensaries are scattered through the country, it has not yet been carried out on the scale which its importance deserves.

1835. *Oxford*.—The Medical Benevolent Fund was founded.

1840. An elaborate report on vaccination by Mr. Ceely, costing the Association no less than £700 for illustrations, and which is still recognised as the standard authority on the subject, was followed by the prohibition of inoculation, and led to legislation which is even yet only partially successful in checking the ravages of small-pox. The Physician to the Emperor of Russia joined the Association, and influenced the Russian Government to register the causes of death in that empire.

1842. Life assurance offices prevailed on to pay the fees of the medical referees.

1848. The retrospective addresses delivered at each annual meeting led to the publication of Braithwaite's *Retrospect and Ranking's Abstract*.

1849. A petition to Parliament to check the Sale of Poisons was speedily followed by Lord Carlisle's Bill to regulate the sale of Arsenic.

1864. Failure of Medical Provident Fund.

1866. This year will ever be memorable in the annals of the Association by the death of Sir C. Hastings, its founder, who for five-and-thirty years had devoted himself to promote the best interests of the profession.

*Poor-Law Medical Relief*.—Among the subjects which have prominently engaged the attention of the Association, Poor-law reform deserves special mention. So early as 1836, it was recommended that the parish should pay for drugs. This advice has been followed in many unions to the extent of furnishing cod-liver oil and quinine, and, in large towns, will perhaps shortly lead to the formation of dispensaries, where the poor will obtain the medicines prescribed by the parochial medical officers.

1839. In this year, in consequence of the remonstrances of the Association, the system of tendering for medical Poor-law appointments was abandoned. This practice had led to such results, that we find it officially stated that two hundred and thirty-three Poor-law medical officers were practising without legal qualification.

1870. In this year, the superannuation allowance was extended to Poor-law officers. It must be confessed that the efforts of the Association directly to improve the status of the Poor-law medical officers have hitherto been attended with very partial success; not from any want of zeal, but because the power which competing corporations possessed to facilitate the admission into the profession of imperfectly educated practitioners has enabled the guardians of the poor to dictate their own terms.

*Medical Reform, 1837. Cheltenham*.—Perhaps in no way has the Association done more for the public good than by its efforts to promote medical reform. In 1837, a Committee was appointed to watch the interests of the profession; and it was recorded that the power of granting qualifications was vested in no fewer than seventeen competing corporations, underselling each other like a Dutch auction. The Committee noticed the imperfections and unequal character of existing methods of qualification for medical licences, and the insufficiency and exclusiveness of medical corporations, with want of power to afford protection to the public and the profession against the arts of ignorant pretenders. It urged the importance of the one portal system, and advised that the profession should be represented; that the uniformity of primary qualification should be tested by sufficient examination; that there should be an equal right to practise throughout Her Majesty's dominions. These remonstrances for the time availed little. In 1842, we find that the College of Physicians denied the right of the Association to interfere. The College of Surgeons considered themselves immaculate; and Mr. Guthrie did not see anything to amend.

1846. In this year, registration of practitioners was recommended—a course afterwards carried out by the General Council with marked advantage.

1852. The Royal College of Surgeons was compelled to accept a charter giving Fellows the right to vote—a measure to which the important improvements lately adopted by that body can be distinctly traced.

1858. I need not weary you with the details of the struggle which ensued, and which, after having been carried on several years, ended in the passing of Mr. Cowper's Act granting:—1. Registration of qualified practitioners, with exclusive right to hold medical appointments and to recover remuneration; 2. Reciprocity of practice; 3. A national *Pharmacopæia*; 4. Establishment of a Council with power to exclude from the Register for infamous conduct—a clause which promised to be of very great value. The chief defects of the Act were that it made no adequate provision for uniformity of professional education, and that it failed to give the general practitioner any voice in the selection of the Council. This last provision is well known to have been long regarded by the Association as of great importance; and its omission recently caused the rejection of an otherwise very valuable measure of medical reform. A recommendation made several years since may prove a good compromise; namely, that the General Council should remain unchanged, but that the Councils of each corporation should be elected by the members of each corporation, the right of voting not being restricted to a select few.

*Quackery.*—At the foundation of the Association, there was a spirit of disunion with no recognised standard of authority; and probably in no way has the Association been of so much service as in its indirect effect on the profession. Medical associations must tend insensibly to form a standard of conduct and feeling to which the majority will by inclination happily conform, the few from motives of self-interest.

Our late friend and colleague, Dr. Cowan, was especially noted for his denunciations of all forms of quackery. At Liverpool, in 1839, he had the boldness to attack, and, in spite of the opposition of vested interests, the good fortune to destroy, an institution supported at Liverpool by many of the chief practitioners of that town, and which possessed a stock of no less than £1,500 worth of patent, and therefore secret, nostrums, there being at that time no fewer than six hundred stamped patent medicines; whilst advertisements were daily issued by those holding diplomas, vying with each other in their gross disregard of truth and decency.

In 1849, the President of the Taunton branch was expelled from the Association for consulting with an unqualified practitioner—a warning which has not required to be repeated. The recent defence of such conduct in Ireland shows how greatly the influence of such an Association is needed in that country.

I must not omit to remind you of the public condemnation of the Royal College of Physicians of Edinburgh. To their lasting disgrace, they had proclaimed what they called a year of grace—that is to say, they replenished their coffers by the sale of licences without even the pretence of any investigation, but easily satisfied with the signatures of two medical friends of the candidate for the diploma.

*Homœopathy.*—Perhaps in no single instance has the Association done so much good as in defining the duty of its members towards the practitioners of homœopathy. At the annual meeting held in Brighton in 1851, it passed resolutions condemnatory of the practice of meeting homœopaths in consultation. In 1857, Dr. Horner, a Vice-President of the Association, was unanimously removed from his position on account of his having adopted homœopathy. The Association did not cease reaffirming its opinions, till it became an accepted axiom that under no circumstances could medical men hold professional intercourse with practitioners of homœopathy. The importance of this decision will be estimated at its true value when it is recollected that up to this time some of the leaders of the profession, whilst deriding the practice of homœopathy, had not ceased publicly to proclaim their willingness to consult with homœopaths, setting at defiance the well known rule of medical ethics, that when the opinion of two consultants are irreconcilable, it is the duty of one of them to retire. But from this time (1861) no such conduct has been permitted.

I began by stating that, when the Association was founded, medicine was partly a trade, partly an art. I firmly believe that the trading portion is a thing of the past; that it is now partly an art, but day by day more nearly approaches a science. The apothecary of the past is displaced by the highly educated practitioner of the present. The energy of ignorance, which in times past was frequently so dangerous, is but seldom to be met with. The poor can obtain the highest skill. But in no respect is the advance so great as in the altered tone of professional feeling. To be held up to the reprobation of the profession has become one of the greatest of punishments.

Brief allusion has been made to some of the successes achieved by the Association; others even greater must follow. The one portal system is but a question of time. The proper representation of the

profession depends on the energy with which the struggle against vested interests is carried on.

Do not suppose that in claiming so much for the Association I desire to undervalue the important aid which has been received from the different medical journals; but, as the Association is the only recognised expression of professional feeling, without doubt it deserves the greatest share of the praise, in spite of the opinion expressed in certain quarters, "that its conduct is little else than a disgrace to the professional body of this country; annual meetings, feasting, toasting, guzzling, complimenting, and puffing forming the chief features of that stupidly managed Society, the British Medical Association."

[An interesting pendant to the friendly and complimentary observations here quoted by Mr. May concerning associations such as our own, are contained in some observations of Professor Virchow quoted in a letter which we have received from our able correspondent in Berlin.]

## ABSTRACT OF A CLINICAL LECTURE ON THE MODE OF INVESTIGATING THE DISEASES OF WOMEN.

By ROBERT BARNES, M.D.,

Obstetric Physician, and Lecturer on Midwifery and Diseases of Women and Children, at St. Thomas's Hospital.

GENTLEMEN,—I have now a few general observations to make to you on the mode of investigating the diseases of women. In a former lecture, I told you that we were guided by the subjective sensations of a woman in our first investigations. When a woman complains of aching and pain in a part, we are naturally led to conclude that there is some mischief going on in the seat of pain, although there is no absolute certainty until we examine the organs suffering. In single women, we are chiefly guided by some disturbance of the function of menstruation. In many cases of disturbed menstruation, there exists some morbid condition which it is necessary to investigate. If there be intense pain and leucorrhœal discharge, we get the indication of disease requiring exploration. Discharges especially are significant, and render examination imperative. No woman suffers long from distressed menstruation or a discharge without danger of mischief. By examination, then, you come to a large class of *objective* signs, which, taken in conjunction with the *subjective* signs, throw great light upon the disease. From the two together, you may come to a rational view of the case.

First, then, as to the ovary. The ovary is recognised now as the *primum mobile*, the first cause of menstruation. When menstruation is disturbed we should look to the ovary; although the uterus, being the organ of the discharge, should be looked to also. Still, if there be no ovary, there is no menstruation; if the ovary be diseased, there is likely to be difficult menstruation.

There are diseases, however, having their primary seat in the uterus. The uterus has a certain definite position, size, shape, mobility, or range of motion, sensibility and attachment. All these conditions can be examined by the touch, and any deviations from them must have a cause. There are some other properties of the uterus which we can bring under observation—such as its vascularity, colour, and alterations of surface. The speculum enables us to see the lower part of the uterus and the vagina, and is here of the greatest possible service; but nothing, of course, can enable us to see the ovary.

[Dr. Barnes then referred to a diagram of the uterus and its appendages in the healthy state, and proceeded to show how its position was affected by abnormal conditions.] If there be a large quantity of urine in the bladder, the uterus is thrown backward; if the rectum be loaded, the uterus is pressed forward. Sometimes the uterus is from this latter cause so pressed against the bladder that there is retention of urine. I have known distressing cases of this kind. There are no means of keeping the bladder free until you have washed out the rectum. As to change of size, if the uterus be much enlarged, and the other signs of pregnancy agree, we conclude that the woman is pregnant; but the minor sizes of the uterus are not so easily settled as the result of pregnancy. They may be the result of engorgement, or of mischief coming on after pregnancy, or of tumours, etc. If at the end of three weeks from confinement we find that the uterus is large, we conclude that involution of the uterus has been arrested. The best way to ascertain the bulk of the uterus is to grasp it between the two hands. The sound will also measure the size of the uterus. The change of form chiefly indicates the presence of tumours in the uterus, which, springing out of its walls, alter its shape; or it may indicate a displacement. We ascertain the sensibility of this organ by the touch. Tenderness on pressure may arise from inflammation, or neuralgia, or irritability. There is supposed to be a simply hyperæsthetic condition of the organ, the slightest touch

giving acute pain; the tenderness may also arise from hysteria. In the normal state its sensitiveness is very slight.

There is another sign of great importance in ascertaining the true condition of the uterus—change of density or hardness. The os uteri, in the unimpregnated state, is as hard as the point of the nose: it feels firm, smooth, and hard. If that condition be altered to softness, you may suspect pregnancy; but of course you would not rely upon that sign alone. Another meaning of the softness is increased vascularity, which may arise from a granulating surface, the result of lost epithelium. If that be combined with increased size, patency, and leucorrhœa, we are pretty sure there is inflammation of the cervix uteri. Cancerous growth in the cervix may also help to keep the os open.

The significance of altered mobility is very important. The uterus naturally moves about, and if it do not, you have to consider a number of causes which impede it. A large fibroid tumour will sometimes fix the uterus. Cancer almost invariably alters the mobility of the uterus. Of all things this is the great test of cancer. In the earlier stages, indeed, it affects only the cervix; but when it has invaded the roof of the vagina, the bladder, and rectum, then you get a dense, firm mass, filling the brim of the pelvis, which you cannot move. There are conditions about the os which make this sign still more clear: the history also will guide you. After labour or abortion, you may have inflammation of the pelvic peritoneum; and this is sometimes attended with great effusion of plastic matter, which sets the uterus and surrounding structures fast together. The history will also guide you here. In the case of cancer you can see the disease, and find cancerous bleedings and discharges.

There is another cause of fixed uterus: the pouring out of a quantity of blood behind it—the so-called retro-uterine hæmatocele, a very interesting example of which is now in the hospital. This condition is always accompanied by pelvic peritonitis. This is distinguished by the os uteri being pushed against the symphysis pubis, and the sound passing upwards and forwards towards the umbilicus. This determines the position of the fundus of the uterus, proving that the mass felt behind the os cannot be the body of the uterus. The history and other signs, then, lead to the diagnosis of hæmatocele.

The significance of the several discharges we must consider on another occasion.

## ABSTRACT OF A CLINICAL LECTURE ON A CASE OF CANCRUM ORIS,

AND ON CASES OF EMPYEMA IN YOUNG CHILDREN, TREATED BY PARACENTESIS THORACIS.

*Delivered at King's College Hospital, November 2nd, 1871.*

By W. O. PRIESTLEY, M.D.,

Professor of Midwifery in King's College; Obstetric Physician to King's College Hospital.

*Cancrum Oris.*—I wish to call your attention to some cases which we have had in the Pantia Ralli Ward. The first is one of comparatively rare occurrence, in which the child has died from rapid sloughing of the mouth. This little child, named Elizabeth Sowman, aged two years and seven months, was admitted on October 12th, suffering from marasmus and bronchitis. She was so small and emaciated that she weighed only 9½ lbs., the average weight of children at birth being 7 lbs. She had got a very inadequate supply of nourishment from her mother, and she suffered from convulsions at six months. When she was admitted, the skin hung in folds about the limbs; the joints were very large; the anterior fontanelle was still open. She was very feeble, sleepy, and sometimes fretful, but had no sickness or purging. Abundant small crepitant *râles*, with occasional sibilus, were heard all over the chest; the respiratory sounds were very feeble, and some dulness existed under the left clavicle. The abdomen was tumid, and enlarged glands could be felt.

The child was ordered to be well rubbed with warm olive oil night and morning, after the method recommended by the late Sir James Simpson, who, in making inquiries about the health of the children in wool-factories, found that they were plump, and very seldom affected with the various forms of struma and consumption. He thought this was in consequence of the oily nature of their employment, as in flax-works the workers had the same amount of these complaints as other people, or rather more. He therefore recommended external oil-rubbing as a means of improving the nutrition of emaciated children. This child was put on milk-diet and wine, with a teaspoonful of cod-liver oil three times daily. On the 14th October she remained much in the same state; and, as the bowels were rather confined, she took a drachm of senna-syrup. On October 17th she was very restless; and had much dys-

pnoea, with abundant crepitant *râles* all over the chest. On this day the inside of the lower lip showed for the first time an inflamed circumscribed aphthous patch, to which was applied a lotion of chlorate of potash and borax. Next day the patch had assumed a sloughy appearance, and had spread rapidly; and the child was consequently ordered a full allowance of brandy daily. On October 19th she was much weaker; the sloughing of the lower lip extended; and, as the two front incisors seemed to irritate the slough, they were removed. She was taking her food very well, and was ordered to take, three times daily, three minims of tincture of perchloride of iron, with syrup. On October 20th, the lower lip was perforated by the slough, which kept extending. The edges were black and ragged, and discharged offensively. The bowels now became relaxed; the pulse rose to 168; the temperature was 99.2, and the respirations were 60. She slept very badly, and coughed much. On the 21st, the ulceration presented a large ragged excavation of the lower lip and gums, and a lotion of chloride of zinc, 15 grains to an ounce of water, was ordered. On the 22nd the child grew very weak. The chasm extended to the chin, and measured an inch and a quarter across. On the 23rd she was still worse. On the 24th the whole of the lower lip had sloughed away, and the gums at the root of the teeth were involved in the gangrene. The breathing was very rapid, and crepitation was heard over the whole of the lung-surfaces. The pulse was almost imperceptible, but she yet took food well. Next day she sank suddenly, and died at 9 A.M.

This sloughing of the mouth is suitably called *cancrum oris*, or *gangrenous stomatitis*. There has been a good deal of confusion as to the varieties of stomatitis—so much so that Dr. West has proposed to divide the forms of it, and call only the more of the two milder forms severe *noma*. This term "*noma*" has been applied to all the forms of the disease. It was used by Hippocrates to indicate all ulcerations about the mouth. But as it is no doubt very desirable to simplify the nomenclature of disease, and at the same time have accurate definitions, you may advantageously adopt the terms proposed by Dr. West; viz., *follicular stomatitis*, the simple aphthous ulceration of the mouth; *ulcerative stomatitis*, or *noma*, the somewhat more severe affection in which the aphthous inflammation extends to the gums, covering them with a pulaceous exudation, and producing ulceration round the teeth; *gangrenous stomatitis*, or *cancrum oris*, in which true sphacelus of all the tissues occurs, and the loss of substance is both rapid and irreparable. This last form begins generally on the inside of the mouth: some authorities think in the cellular tissue or deeper structures, and others in the mucous membrane. Be this as it may, in the case before us the ulceration began as an aphthous or ulcerated patch on the mucous membrane inside the lip, thence rapidly sloughed through all the tissues, and gradually destroyed the child from exhaustion. Gangrene of this kind only occurs in very feeble children, and is most common after measles or scarlet fever, particularly measles. Where the child is much debilitated, there may be no antecedent illness.

As to the treatment, although it has been recommended generally to apply strong caustics so soon as the character of the ulcer is seen, it was felt that it would have been a cruelty to do so in this case. The child seemed half dying when brought to the hospital. In Philadelphia Hospital, however, the nitrate of silver in stick was used, and many cases recovered. Some authorities recommend the application of strong nitric or muriatic acid; and there can be no doubt that, if one could stop the gangrenous process and make the wound take on a healthy surface, there might be hope of recovery; but in a feeble child like this, such treatment was impossible. We had to be content with minor measures, and indulge the remote hope that, by soothing applications, the wound would take on healthier action. The poor child, however, died suddenly, and from the first gave little hope of recovery. This form of sloughing generally occurs in cachectic children, and sometimes bores right through one cheek. It is, perhaps, more frequent in the cheek than anywhere else. Occasionally it affects the genitals of both male and female children, and in these cases, as well as those in which it affects their face, if there be any evidence of power, it would be good practice to apply a strong remedy to check it, particularly as escharotics can be applied under chloroform: but one must be guided entirely by the condition of the patient in judging of its propriety. It was surprising to see this child, ill as it was, take its food readily to the last; but such is sometimes the case.

*Pleuritic Effusion: Paracentesis Thoracis.*—The other cases to which I wish to call your attention are instances of effusion of fluid into the pleura, for which paracentesis thoracis has been practised. You are aware that the symptoms of pleurisy are generally ushered in with pain in the chest, hurried respiration, and fever. The coughing often gives intense pain until fluid is poured out into the pleura; but even then a child is feeble and restless, with exacerbations of feverishness; and it cannot lie easily except in some positions.

I must not here enter into the various physical signs indicated by percussion and auscultation. I will merely remind you that commonly one side expands imperfectly in respiration, while the heart is pushed over to the right side from the presence of fluid; and eventually, if the fluid be not absorbed, although it may at first be serous, it is apt later to become purulent. Although this is the common mode of attack, yet I wish to warn you that there are chronic cases of pleurisy in which there are no such antecedent symptoms. Perhaps there is no history of a febrile attack to be traced. We have seen in this hospital a considerable number of cases of copious pleuritic effusion in children, where no distinct history of acute pleurisy could be made out, and its progress had been so insidious that it was unsuspected. Now, supposing that the symptoms do not yield to ordinary remedies, are we justified in tapping the chest and letting out the fluid in young children? In determining this question, it must be remembered that the fluid in these cases often becomes purulent, and then there is a fresh accession of fever, the child becomes hectic, the tongue is redder, and there are probably diarrhoea and sickness. The cavity of the pleura, indeed, then becomes a large abscess, and the child is in grave peril. Two very favourable cases have occurred at an interval of twelve months in this hospital. One case has gone out recently, convalescent. I confess that for some time I viewed unfavourably the operation of paracentesis thoracis in these cases. What I had seen and read of it abroad was by no means encouraging. M. Boyer had not a single favourable result in all his cases. Dupuytren had only two successful cases out of fifty. M. Gendrin did not save one child in twenty! But a paper was published some years ago in the *Guy's Hospital Reports*, in which much better results are recorded; thirteen out of twenty-five recovering, and in some of the fatal cases death taking place from causes apart from the operation. Dr. West has come to think that we may tap the chest more frequently, and that children are possibly lost in consequence of it not being done.

I have now seen several cases where the operation was followed with good results. Here is an example. James Busby, aged 8, was admitted into the Hospital on June 6th, 1870, with pleurisy, becoming worse and worse. He had to be propped up in bed from excessive dyspnoea, and would have sunk unless the operation had been performed. Various measures were had recourse to before the operation—such as blistering, dry cupping, etc. On the 29th of June, the symptoms were extremely urgent; and on the 13th of July, as a last resource, the pleura was tapped by Mr. Wood, at the suggestion of Dr. Playfair. Thirty-six ounces of thick pus were drawn off through a tube under water, immediately after which he breathed more easily, passed a quiet night, and next day was more comfortable than he had been for a month before. The line of dulness was moved back three-fourths of an inch nearer the median line. On the 20th of July, the pleura had filled again, and the boy was apparently as bad as ever. There was considerable bulging in front of the ribs, just below the left nipple. Mr. Wood passed a trocar through the old wound, and drew off nine ounces of pus, which gave him no relief. Next day, the dyspnoea was still greater; the bulging in front was larger, red, and tender, looking like an external abscess, and poultices were applied. On the 24th, he seemed at the point of death from dyspnoea, and the house-surgeon opened the swelling at the most prominent part with a bistoury. Eighteen ounces of pus gushed out, and for a week afterwards the discharge was very profuse, soaking the bed-clothes three or four times daily. Oedema of the feet came on; and on August 7th, both legs and thighs were much swollen, and diarrhoea set in. For this he was treated with opium, catechu, and kino unsuccessfully; and on the 19th, the diarrhoea was so excessive that all food was stopped except raw meat pounded with sugar, and a liberal allowance of brandy. The second left rib was separated from its cartilage, and could be felt moving up and down under the finger. In a few days, the diarrhoea diminished; the boy began to improve and gain flesh. On the 19th, as no discharge took place, a counter-opening was made through the back of the chest, and a drainage-tube was put through from front to back. On September 16th, a smaller tube was substituted; and on October 20th, this was altogether removed. He was then plump, walking about the ward, though still weakly. The left side measured 10½ inches, one inch less than the right, and was tolerably resonant; there was vesicular breathing, with some small crepitation; and the heart had resumed its normal position. On Nov. 4th, he was sent away convalescent. In reference to the narrowness of the chest in this case, it must always be expected to follow to a greater or less degree; and there is little chance of the chest regaining its entire fulness again—it probably remains always partially collapsed, although there is great tendency in nature to repair the injury. Dr. West has suggested a peculiar belt and crutch to be used after treatment in hospital to lessen this deformity, and has seen children improved by its use.

The second child on whom paracentesis thoracis was performed has just left the ward. The notes are as follows. Annie Webb, aged four years, was admitted on the 19th July, with some dulness of the left side of the chest, diarrhoea, and abdominal pain. She had cough, and was restless. The temperature was 103 deg., and the pulse 136. The cough increased; and, on the 23rd, there was dulness over the whole of the left lung, with diminished respiratory and vocal sounds. The left side was slightly larger than the right, and the spinal column was curved from the left. On the 26th, the left side was painted with iodine liniment; but, as this took off the skin, it was not repeated. On the 28th, as she was coughing much, restless, and thirsty, she was given two drachms of cod-liver oil twice daily, two ounces of wine, and an extra pint of beef-tea. Notwithstanding this treatment, the pleuritic effusion increased so much that, on the 6th August, the intercostal spaces were bulging, and the most perceptible heart-impulse was between the sternum and right nipple. On the 16th, the chest was tapped under water, and a tube inserted, through which two ounces of very thick pus flowed. Considerable quantities of pus escaped daily. On the 25th, some purulent material was coughed up, the edges of the wound sloughed, and the tube was withdrawn. On September 2nd, the pleura was syringed out with one part of tincture of iodine to five parts of water. After this, the discharge became less, and great improvement was manifest in the girl's health. On the 30th, she had lost her cough; the wound was rapidly contracting, and very little discharge of pus; the heart was in its normal position, and a considerable quantity of air could enter the left lung. The abdominal pain in this child was very likely to mislead the practitioner, and make him suspect some abdominal affection. It is well to be upon one's guard in this matter. When a child complains of pain in the lower part of the chest or upper part of the abdomen, you need not necessarily suppose that it is suffering from peritonitis or inflammation of the bowels. Examine its chest carefully, especially if it have cough. Most frequently cases of this kind turn out to be pleuritic, and not abdominal. When the chest begins to bulge on one side, there is then no doubt that there is the effusion of pleurisy. I have no doubt, gentlemen, that in this child's case tapping was a very judicious measure; and I feel certain that this operation will come to be the recognised method of treatment in such cases.

## ON INTRAOCULAR MYOTOMY.\*

By AUGUSTIN PRICHARD, F.R.C.S.,

Consulting Surgeon to the Bristol Royal Infirmary and Eye Dispensary,

It has been my desire for some time to bring before you some of the results of this operation on the eye, the method of performing which I will presently describe. We of the elder generation in our student days were taught that the firm grey ring, about an eighth of an inch in width, joining the iris and choroid, and lying a little behind the junction of the cornea and sclerotic, was a ligament, and it was therefore called the ciliary ligament; but it was also added that some older anatomists considered it a ganglion, and others even thought it muscular. It was obvious, however, on minute dissection, without powerful microscopic aid, that it received numerous branches of the ciliary nerves, which ran forward imbedded in the grooves on the inner surface of the sclerotic; and that a few were traceable through its tissue into the iris; and also that some nervous twigs seemed to emanate from loops whose direct continuity with the ciliary nerves it was difficult to trace. These latter, I need scarcely remind you, come from the lenticular ganglion, and consist of branches of the third or motor, the nasal branch of the first division of the fifth, or the sensory parts, and the sympathetic; besides the two long ciliary nerves which leave the fifth nerve before it joins the ganglion, and enter the globe of the eye along with the others; one of these two anastomosing with one of the short ciliary twigs before it pierces the sclerotic, thus, independently of the nervous supply to the lids, conjunctiva, muscles, and other appendages of the eye, forming an extremely complex arrangement of nerves running forward to the ciliary ring. This peculiar structure is now acknowledged to be muscular, composed of non-striated fibre in the human subject, but of striated fibre in some of the lower animals; having its fibres directed principally in two sets, one circular, and the other radiating, but much intermingled; the whole forming so firm a ring that, when there is effusion within the globe of the eye, that is, inside the choroid, the sclerotic itself, dense and inelastic as it is, rather yields than this band, which forms a constricted line round the hardened globe. In those rarer cases where the whole eye, including this band, is distended with fluid, the sight is hopelessly gone.

\* Read before the Bath and Bristol Branch, October 26th, 1871.

The operation to which I allude is the division through a small aperture of these muscles and the areolar tissue and nerves, which together form the so-called ligament; and it is easily performed, without much pain, and not needing chloroform. Mr. Hancock and Mr. Solomon, and some others, have written on the subject; and Mr. Solomon, who seems to have a large experience of it, lays much stress on the difference between division of the longitudinal and radiating fibres of the muscle, and advises a special way of operating, so as to ensure the division across the radiating fibres; and he brings forward some cases of much interest and success, where he has performed his operation for the cure of various defects in the accommodating power of the eye. I am not convinced of the reality of this difference, and believe that, if the whole grey body be cut through, the fibres of all kinds must be divided, and the action of the muscle modified and impeded; and, independently of any effect on the muscular and nervous elements of the organ, the dense unyielding ring can no longer afford the mechanical resistance which it has hitherto given.

Unfavourable results of the operation are extremely rare, the usual local objective consequences being an immediate effusion of blood, sometimes filling the anterior chamber, which, however, is absorbed in a day or two; a slight protrusion of the choroid or even of the hyaloid membrane; a gradual leakage of watery fluid from the chambers; and a dragging of the pupil downwards towards the opening. The other results vary according to the case.

The operation is generally performed with a cataract-knife; but I very much prefer the iris-knife, a little instrument which has undeservedly fallen into disuse. It is a knife about as wide as the blade of a cataract-needle, cutting on one edge only, with a smooth and round back, being tolerably strong for its size. The surgeon stands behind the patient, and, steadying the head and eyelids as in the extraction of cataract, with the knife pointed vertically downwards, its back being towards the globe, lets the point enter the cornea about a line from its lower margin, and pass onwards through the iris close to its ciliary border, into the space between the edge of the lens and the sclerotic; then, by pressing the edge forwards against the sclerotic, and letting the little knife partially cut its way through, the ciliary muscle must be divided. Before the instrument is quite withdrawn, it should be slightly rotated, so as to allow a free escape for the aqueous humour and any blood which may have been effused during the operation, and of any fluid that may be collected at the roots of the ciliary processes and round the ciliary ring.

The cases where this operation will be of service may be stated generally to be those where the sight is dim, the eye unusually tense and hard; in chronic recurrent iritis with effusion; in glaucoma in all stages; and in sclerotic inflammations which are accompanied with increasingly impaired vision and much circumorbital or hemicranial pain: in fact, in those cases where iridectomy is successful. And it is quite different both in a physiological and practical point of view from mere puncture of the cornea or evacuation of the aqueous humour, or tapping through the sclerotic in cases of hydrophthalmia, recommended by Wardrop and others. I am not prepared to say that this proceeding is a complete substitute in all cases for iridectomy; but it has the advantage of being quite safe and simple, and comparatively a slight operation, not requiring chloroform, and productive of little injury to the eye. It gives time for other treatment, and for iridectomy itself, should that measure be advisable. I am quite aware also that some of the highest ophthalmic authorities in London have no opinion of its efficiency; but this I make bold to put down to want of experience, from lack of faith in its merits. I believe also that, in cases where this operation proves entirely useless, iridectomy will prove useless too. I have performed the operation as I have described it a great many times, and the general result is as follows.

In one old gentleman, who was quite blind, there was supuration of the globe; and this, the only untoward consequence I have met with, was due to the patient's imprudence. In many other cases, the result has been negative. In very many instances of progressive disease threatening the sight, the complaint has been checked and a portion of sight saved; and in many others the sight has very much improved, and freedom from pain ensued. It is worthy of remark, that I have never seen a return of glaucomatous disease in an eye thus treated; and also that it is only in bad and unpromising cases, where other treatment proved unavailing, that the operation has been performed.

I must briefly narrate to you some of these cases, in illustration of what I have described.

**CASE I. Glaucoma.**—One of the first cases in which I performed it, was in a poor woman blind for some time with one eye with what used to be called amaurosis. She was under various general and local treatment for it when the other eye became suddenly dim; and she was brought up to the Eye Dispensary almost blind a few years ago. The

pupils were dilated and fixed, but not yellow or glaucomatous in appearance; and she suffered extreme pain in the sides of the head. We tried the treatment usual in such cases—blisters, iodides, and local stimulating applications to the eye; but she grew gradually worse, and it appeared certain that nothing but operation would give her any chance, and that a very poor one. I therefore went down and performed intraocular myotomy in a little back street in the Hotwells, my friend Mr. Leonard kindly giving me his help; and there we left her, without much hope of amendment. We saw nothing of her for some weeks, when she presented herself, but so altered that I did not recognise her as the same person. She could see well; and the change in her showed the difference between the vacant look of a blind person and the active expression in the eyes of one who sees.

**CASE II.**—In an old lady, who was blind except that she could distinguish light from darkness, who was very old, and whose case was very chronic, the operation in both eyes resulted in the restoration of sufficient sight to enable her to go about with comparative comfort.

**CASE III. Subacute Glaucoma.**—A little weakly nervous old lady, of excessive timidity, suffered from glaucoma of the left eye, which had almost destroyed her vision when I saw her. By a sort of ruse we got her to submit to chloroform, to which she was very unsusceptible; and I then removed a piece of iris; and, finding the lens partly opaque, removed that also. She recovered the strength of the eye, but saw barely the light. Two or three years afterwards, the right eye became similarly affected, with much pain in the head and fullness of the vessels. No treatment seemed to touch it, and neither she nor her friends would hear of any operation. At one of my visits, however, I went armed with my little knife, and, partly by stratagem and partly by force of arms, I got hold of her head and made the required puncture before she well knew what was the matter. From that time the pain in the head left her, and the eye soon became strong. The sight remains much as it was just before the operation, and she finds her way about tolerably well. I have no doubt that she would have been blind in a very few days, if the disease had continued unchecked.

**CASE IV. General Ophthalmitis.**—An old lady was advised by her medical man to put herself under my care, as his remedies had failed to relieve her of a very painful and active disease in one eye. When I first saw her, she had pus in the anterior chamber, a partly opaque and rough cornea, long standing iritis, and inflammation of the sclerotic, with intense pain in the eye and half over the head, as severe a case as we often see. I thought, however, that I could cure her by general treatment and local applications; and with tonics and other means she became much better, but in a very short time returned to Clifton as bad, if not more suffering than ever. The sight was hopelessly lost; but she suffered so much pain, that she was precluded from any enjoyment of life, and from performing her duties. I therefore determined to try this operation, and made a free puncture in the way described. She shrieked out at the time, and suffered very great pain for some hours afterwards; but went home in three or four days quite relieved, and has remained well ever since.

**CASE V. Acute Glaucoma.**—A woman, between 50 and 60 years of age, came up from the country with well marked acute glaucoma, a comparatively rare disease, generally affecting both eyes, probably gouty or rheumatic in its origin, known by enlarged fixed oval pupils of a green colour, rapid destruction of the sight, and, as far as we now know, only to be relieved by operation, and, before the date of iridectomy and intraocular myotomy, incurable. The disease had existed five weeks, and had already destroyed the sight, except that in one eye there was a faint perception of light; but this was only occasional. The eyes were very hard and prominent, but not very vascular. The lens looked hazy, and the iris was pressed against the cornea in each eye; and she suffered extreme pain in the head. Her medical attendant in the country had treated her with great activity, and had done all that leeches, blisters, mercurial and other medicines, could do; and they would have relieved her, if any internal remedies would; but the disease held its course. In this case there was every expectation that an operation would remove the pain and check the disease; but I could give her no definite hope of a restoration of the sight, which seemed to be lost. I divided the ciliary ligament freely in each eye, letting out a large quantity of fluid and some blood. She complained of much pain at the time of the operation, and for some days afterwards. On the fifth day, she became easy, and stated that she could see the light and her hand moving; and from this time she gradually and slowly mended, and, when I last saw her, she was quite free from pain, and her eyes were strong. She could see fairly with both eyes; that is, she could find her way about, and see all objects about her tolerably clearly; and the sight was still mending. The pupils had become black, but were still very large and pointed below, being drawn down at the seat of the operation.

I have chosen these five successful cases to show the occasional value of the operation in different states of the eye. I have not yet tried it in corneitis and pannus, but intend to do so. There is no claim to novelty in what I have now brought forward; for I believe that others have done the same, although the mode of performing the operation may not be identical. But I must very briefly speak of this operation in another point of view, in which I think it of much physiological and pathological interest and value, and which, to my knowledge, has not been previously noticed.

In one of my papers, on Extirpation of an Injured Eye for Sympathetic Ophthalmia of the other, I stated that, from examination of the removed eyes, I found that in a large majority of cases the sympathetic ophthalmia occurred where a cut had divided the cornea and iris, and destroyed the lens, and left a hardened and adherent capsule pressing on the ciliary ligament; and that it was the diseased action of the compressed nervous structure of this organ which, through the sympathetic and fifth nerves, led to the development of sympathetic destructive disease of the uninjured eye.

It must be admitted that the nerves passing to the grey ciliary ring control and superintend the nutrition of the anterior part of the eye, for there is no other nervous supply; and the nutrition of the eye is modified, or impaired, or improved, according to the condition of the nerves. The pressure on this ring produces blindness of an incurable kind, if of any moderately long standing without suitable treatment; and it generally leads to similar disease of the other eye; and, as the removal of a diseased eye checks the progress of complaint in the other, so I believe, and am prepared to show by some cases, that division of the muscle in an eye blind from pressure on the nerves will alter and improve the nutrition of the eye operated on, and will check the progress of disease in the other.

**CASE VI. Disordered Nutrition of the Eye altered by Operation.**—In the year 1868, I removed the left eye of a young man who was blind from injury and sympathetic ophthalmia. The remaining eye was at that time affected with the bulging and thinning of the sclerotic coat round the margin of the cornea known as "staphyloma corporis ciliaris", and he could just discern the light. This state became worse; and after a while, merely to relieve the tension and pain, I performed intraocular myotomy, and he went back to the Union, of which he was and is an inmate. When I next saw him, the eye had nearly recovered its usual size and shape; the pupil was closed, and most of the cornea opaque; but there was a firmer and healthier feel about the eye, and the staphyloma had disappeared—a circumstance which I never witnessed before; and he could still see the light. In June of last year (1870), I made an attempt to remove a portion of iris, but only succeeded in removing a portion of membrane which I considered to be the capsule of the lens. In June of this year, he was again under treatment by Mr. Leonard and myself; and we took out a piece of iris through a section in the upper part of the cornea, where alone it was clear, leaving a pupil of considerable size. This young man can now see objects around him, but not very distinctly. The case, however, is a very remarkable one, and proves that the removal of the tension of the eye and relief from the pressure on the nerves by the division of the ciliary muscle have restored the nutrition of the globe to a comparatively healthy state.

I must lastly give one or two cases to illustrate the effects of the operation on the other eye, an effect most remarkable, and at first unexpected, but perfectly true and unmistakable.

**CASE VII.**—In September 1870, a poor man aged 60 came under my care with the following unpromising condition. He had cataract and glaucoma of the left eye, which was hard, congested, and quite sightless; and with the right eye he could not see his way about. He could see sideways, but not straight before him; and the eye was hard and full. After trying various treatment without effect, I divided the muscle in this eye, and much fluid and some blood escaped; and he complained of much pain. Within three days, he had greatly improved, and could see objects all round him; a fortnight after the operation, he could see very much better, and the pupil was drawn down and active; and, what was most remarkable, he drew my attention to the fact that he could see the light with the old glaucomatous left eye; and, upon examination, I found it looking much more healthy; and the pupil, instead of being fixed, was moderately active. Under these circumstances, about a month afterwards I extracted the cataract, and he saw better. About six months after the first operation, he had fair sight in the right eye, in which the pupil was still drawn down; but in the left, where I had removed the cataract, there were evidences of great tension, the iris being pressed backwards by the fluid. I therefore divided the muscle in this eye also, and the patient was relieved. He can see to go about anywhere, and can see objects moderately well; and he is still under treatment.

This interesting case proves to me the following facts; viz., that

intraocular myotomy will check glaucoma in the eye operated on; that it will, by sympathetic action, relieve a similar state of the other eye; that glaucomatous tension of the eye is not removed by removal of the lens; and that the ciliary muscle may be divided with advantage in a tense eye from which a cataract has been extracted. I have been so convinced of the truth of these inferences, that I have not hesitated to advise, and very frequently to perform, this operation on a hopelessly sightless eye, in order to preserve the other.

**CASE VIII.**—A servant, who had lost one eye completely by recurrent iritis, which had resisted all kinds of medical and topical treatment except operation, and had left her with bulging iris, closed pupil, and hard globe, came under my care with a similar condition in a very acute form in the sound eye. Although she had suffered only a few days, her sight had become extremely dim. I used some treatment without much avail, and then divided the muscle in her sightless eye. Much fluid escaped, and the next day she pronounced herself better. She had no bad symptom; and the recently affected eye answered favourably to treatment, so that the sight was entirely restored; and now both the eyes look more healthy than they did before, and she is able to read and to follow her avocation with comfort.

**CASE IX** was that of a middle-aged woman nearly blind in the left eye from slowly progressing glaucomatous disease resisting all treatment. After a time, the right eye began to be similarly affected; and I then divided the muscle in the left, in which she only saw light. The anterior chamber filled with blood at once. It was absorbed in a few days, and within ten days the sight was much improved. The result has been, that she has useful although imperfect sight in the left eye, whilst the right has completely recovered itself and become perfectly strong and well.

It would be useless to multiply cases of this kind, which much resemble one another; but I think I have brought forward enough to prove the great value of this operation.

It will probably be noticed that I have said nothing about the ophthalmoscopic appearances in these cases. I only examined a small number of them, for in most the symptoms of disease and indications for the operation were obvious. It is possible that, by careful examination of the interior of the eye, we might eliminate from our list some cases in which the operation must necessarily be useless; but they would be very few. The seat of the operation is entirely out of sight under any circumstances; and the only condition which would prove that it would be no use to operate, would be evidence of incurable disease in the retina and optic nerve, independent of pressure within the globe, a comparatively rare cause of blindness. There is, however, a fair field open for careful observation in this respect.

In conclusion, for the tedium and length of my paper, which naturally has not the interest for many others that it has for me, I must ask the forbearance of my audience, and lay the whole blame on the importance of the subject.

#### SUCCESSFUL TREATMENT OF CHRONIC HYDROCEPHALUS.

THE case of Jane Johnson reported in the *Standard* as dying at Leigh, in Essex, on September 26th last, between eighteen and nineteen years of age, recalls to my mind a case which I attended in 1848.

Mrs. R. brought a baby, twenty-two months old, into a room where I was engaged with a difficult labour, observing, "There is no cure for this poor little object." The child had been blind six months; its head measured twenty-seven inches in circumference. The cranial bones, not having grown since its birth, were very far separated from each other. Its neck was about the thickness of three fingers, its legs of one; the abdomen was much enlarged. The mother had been told a year previously by two practitioners of much experience, that there was no cure for it. I told her that it might die at any time; but that if it lived I thought it might be cured. The treatment was commenced November 6th, 1848. It consisted of two grains each of hydrargyrum cum creta, powdered rhubarb, and carbonate of soda, or two grains of hydrargyrum cum creta and one of Dover's powder, according to the state of the bowels, with occasional carminatives. The effect was immediate; the most sanguine prognosis was more than realised. In three months, the child could run alone; at three years, he was foremost amongst his playmates, and whilst at school, the first in his class. He is now established as a watchmaker and jeweller in London, and is the support of his aged mother. Two or three years previously, my father-in-law had been consulted for a girl nine years old, who had been long blind, and whose case for two years had been considered hopeless. Similar treatment, with the addition of blisters to the head, was followed by equally happy results.

HENRY UNPLEBY, M.D., Bedale.

## ON PARALYSIS OF THE BLADDER, AND ITS TREATMENT BY THE CONSTANT GALVANIC CURRENT.\*

By JULIUS ALTHAUS, M.D., M.R.C.P.Lond.,  
Physician to the Infirmary for Epilepsy and Paralysis.

It is a well-known fact that, while some diseases of the bladder, such as inflammation and stone, have received a full share of pathological inquiry and therapeutical attention, other affections of the same organ have been unduly neglected, both as far as pathology and treatment are concerned. To this latter class of diseases belongs the affection known as paralysis of the bladder, which is generally, in text-books on the practice of medicine and surgery, and even in special treatises on diseases of the urinary organs, dismissed with a few cursory and superficial remarks; while in practice patients suffering from this disorder are given over to the use of the catheter for the rest of their lives, and only imperfect endeavours are made to cure a very annoying and troublesome complaint, which almost always, if left to itself, exerts a depressing influence upon nutrition and assimilation throughout the system, and likewise causes considerable mental despondency, with all its attendant evils.

The term "paralysis of the bladder" is often loosely applied to cases in which there is difficult micturition, but where the bladder is not really paralysed. Patients in whom this organ has lost its function of acting as a reservoir for the accumulated urine, are said to suffer from incontinence or paralysis of the sphincter of the bladder; and again, cases in which some mechanical obstruction, such as hypertrophied prostate, offers an impediment to the discharge of the urine, are frequently put down as such of paralysis of the bladder. It can, however, be no matter of surprise that pathological terms relating to disordered micturition should have been vague and inaccurate, if we consider that until quite lately the physiology of that important function has been in a most unsatisfactory condition. Only little was known about the mode in which the motor and sentient nervous supply is conveyed to the bladder, and even less about the muscular forces by which the urine is retained in, and expelled from, that viscus. Before, therefore, proceeding to the immediate subject of this paper, I will give you as concisely as possible the results of some very important investigations into the physiology of micturition, which have recently been made by Professor Budge of Greifswald, and with which, although they have been made known in Germany for some years past, I believe the profession in this country are as yet unacquainted.

Budge made his experiments chiefly on dogs, in which the nervous centres and the bladder were laid bare. It being impossible to determine the course of nervous fibrils from the central organs towards the viscus, by means of dissection or chemical or mechanical tests, the only way to arrive at a satisfactory conclusion respecting the origin of its nervous supply was to observe the physiological effects of electrical stimulation. Now it was found that by faradising the cerebral hemispheres, the corpora striata, and thalami optici, no effect was produced on the bladder; nor did any action become perceptible when the cerebellum was faradised. As soon, however, as the pedunculus cerebri and the restiform bodies were touched by the electrodes, the viscus was seen to contract, and urine was voided. Thus it was made evident that nervous fibrils exist at a certain definite point in the upper portion of the cerebro-spinal axis, which have a special relation to the movements of the bladder.

It now became necessary to determine the course which these fibrils take in order to reach the viscus, and which might lead either through the pneumogastric, the sympathetic nerve, or the spinal cord. Both the pneumogastric and sympathetic were divided without altering the phenomena previously observed; but, after section of the cord, faradisation of the parts just mentioned proved ineffectual. Further experiments showed that these motor fibres of the bladder proceed from the pedunculus and the restiform bodies through the anterior columns of the cord to the anterior roots of the third and fourth sacral nerves, and that their function may be excited both by cerebral influence and by reflex action, the latter through the intermediate agency of the posterior roots of the sacral nerves.

Besides the one just mentioned, there is another nervous centre for the bladder in the lower portion of the lumbar cord, faradisation of which causes well-marked movements of the viscus, and the excitability of which, after death, persists longer than that of any other portion of the cord in relation to the bladder. Motor nervous fibres proceed from

this, independently of those first described, through the hypogastric plexus on their way to the bladder.

Another important result of Budge's researches has been, that the muscle hitherto described by anatomists as *sphincter of the bladder*, is really no sphincter at all, physiologically speaking; and that the longitudinal as well as the circular unstriated muscular fibres of the bladder—that is, the muscles known as detrusor urinæ and sphincter vesicæ—serve exclusively for expelling the urine, without having the least effect in closing up the orifice of the viscus. Faradisation of any portion of the bladder causes urine to be voided; and when Budge caused a column of water to flow in an uninterrupted stream out of the bladder, faradisation of the anatomical sphincter had no influence in arresting the flow. This was, however, immediately checked when the electrodes were directed to the membranous portion of the urethra, acting upon the constrictor urethræ and bulbo-cavernosus muscles. The nerves animating these muscles originate in the pedunculus cerebri, and emerge from the cord between the third and fifth sacral nerves, being enclosed in the sheath of the pudendal nerve. The muscles mentioned habitually close the bladder by means of their reflexory tone—a special arrangement to that effect existing between the posterior roots of the third, fourth, and fifth sacral nerves, the lower part of the spinal cord, and the anterior roots of the same sacral nerves.

The female bladder has, likewise, no sphincter, properly speaking; but the constrictor vaginæ takes in females the place of the constrictor urethræ and bulbo-cavernosus muscles in males. It is, therefore, best to drop the term "*sphincter of the bladder*" altogether, and to call the dense mass of unstriated circular fibres near the opening of the urethra into the bladder the "*annulus circularis*".

Being guided by the results of these physiological researches, we can experience little or no difficulty in satisfactorily explaining the phenomena of micturition, both in their normal state and when they are pathologically altered.

1. The urine is *allowed to accumulate* in the bladder by the reflexory tone of the constrictor urethræ and bulbo-cavernosus muscles. When their tone is considerably increased, as is the case during erection, any passage of urine from the bladder becomes impossible; but if it be lost, there will be incontinence—that is to say, the urine will dribble off as fast as it is secreted. This, however, it would be incorrect to call "*paralysis of the bladder*". Artificial incontinence may be produced by section of any of the parts concerned in keeping up the reflexory tone of the urethral muscles. Thus the urine is seen constantly to dribble away in dogs after section of the *anterior* roots of the three sacral nerves previously mentioned, whereby the *motor* fibres animating the urethral muscles are deprived of their energy; and the same takes place if the *posterior* roots of these nerves be divided, in consequence of which the influence of the sentient nerve-fibres is withdrawn. Either of these operations destroys the reflexory arrangement just described, and, therefore, the tone of the urethral muscles. On the other hand, division of the spinal cord at some place *above* the sacral nerves increases the reflexory tone of all parts below, and, amongst others, of the urethral muscles. In this instance, therefore, the result of the operation is not incontinence, but paralysis of the bladder; the latter being due partly to an increased reflexory tone of the urethral muscles, whose function it is to close the orifice of the viscus, and partly to true paralysis of the motor nerves of the bladder itself.

2. The urine is *voided* in the normal condition by concurrent relaxation of the constrictor urethræ and bulbo-cavernosus, and contraction of the longitudinal and circular unstriated muscular fibres of the bladder. This occurs either by cerebral impulse, or by sentient influence and consequent reflex action. Thus we generally make a point of passing urine just before starting on a railway journey, not because there is any desire to do so, but because we know from experience that for some time to come we shall have no opportunity of satisfying any call of nature. The sentient influence comes into play when the bladder is full and becoming distended, thus causing a peculiar impression on the sentient nerves which imparts to us the desire to empty the viscus. If both cerebral impulse and sentient influence be dulled, as is the case during sleep, no urine is passed; but if they be increased from any cause whatever, unusually frequent calls are the consequence. Thus a general state of excitement and nervousness, which frequently causes diarrhoea, will also cause frequent micturition; and exalted local sensibility of the sentient nerves of the bladder, owing to inflammation of the mucous membrane or the presence of a foreign body, will produce the same result.

Paralysis of the bladder—that is to say, inability to pass urine in the natural way from loss of motor nervous influence—may therefore ensue in the following circumstances.

1. When the conduction of nervous influence from the *pedunculus cerebri* to the bladder is interrupted. This occurs in certain cerebral diseases, in hysteria, in typhoid fever.

\* Read before the Medical Section at the Annual Meeting of the British Medical Association in Plymouth, August 1871.

2. When the influence of the *lumbar portion of the spinal cord* is removed, as in chronic myelitis, certain injuries of the spine, and in atony of the cord. The inability to pass urine is here due partly to paralysis of the motor nerves of the bladder, and partly to an increased reflectory tone of the urethral muscles, which close up the orifice of the bladder and do not allow the urine to escape.

3. When the normal excitability of the *motor or sentient nerves of the bladder* is pathologically altered, without any central affection being present. Most cases of this kind originate in affections of the sentient, not of the motor, nerves of the bladder, and should, therefore, be looked upon as instances of reflex or inhibitory paralysis. This occurs after instrumental interference—such as the operation of lithotomy; after any operation for piles, but chiefly where the actual cautery is used; and after childbirth, owing to the pressure of the head on its passage through the pelvis. Local paralysis of the bladder is also observed after the use of certain drugs which have a special influence upon the nerves of the viscus, such as belladonna and hyoscyamus.

It will be observed that I do not include under the heading of "paralysis of the bladder" cases of *atony* of the viscus from overdistension. The pathology of such cases is quite different. They occur either in consequence of some organic obstruction—such as stricture or hypertrophied prostate, preventing the complete emptying of the bladder; or in people who, on a single occasion, or habitually, for some reason or another, suppress the desire to pass urine. In such cases, the muscular fibres of the bladder become overstretched and lose their tone, but there is not necessarily any failure of nervous power combined with this; and it is, therefore, preferable to avoid the term "paralysis" for cases of this kind.

The treatment of paralysis of the bladder has hitherto, on the whole, been unsatisfactory, more especially that of the first two forms of the disease, where the affection is owing to cerebral or spinal mischief. The remedies most usually recommended and employed are strychnia, ergot of rye, cantharides, arsenic, iron, and faradisation. These remedies have, no doubt, succeeded in curing or improving a number of cases, more especially of the third class; but they have, to my personal knowledge, often remained ineffectual even in such patients, and rarely, if ever, do any good in the cerebral and spinal varieties of the disease. It is especially well known of faradisation, that it has little or no therapeutic influence in diseases of the nervous centres; and, if employed at all in paralysis of the bladder, it should only be used in the local and reflex or inhibitory form of the disease. Under these circumstances it is certainly a matter of congratulation that we possess in the constant galvanic current a remedy which, if properly applied, appears always to be able to restore the influence of volition over the bladder, unless actual destruction of the nervous matter involved should have taken place. From what I have seen of its effects in a number of, at first sight, unpromising cases, I have no hesitation in asserting that, both in efficacy and quickness of action, it is infinitely superior to all other remedies which are generally used for this affection; and that, where there is a physiological possibility of restoring the voluntary action of the viscus, we shall be able to effect it by the aid of the constant current.

The mode of using this agent is of considerable importance. Experience has shown me that it is neither necessary nor expedient to apply the current directly to the tissue of the bladder itself, as we might do by means of an insulated sound, with a free metallic knob, introduced into that organ. Direct galvanisation of the *full* bladder is objectionable, because a powerful chemical decomposition of the urine is the consequence of such a proceeding, giving rise to symptoms of fainting, owing to the sudden distension of the viscus by the gases which are set free; while direct galvanisation of the *empty* bladder appears to produce an irritating effect upon its mucous membrane. External galvanisation produces none of these inconveniences, and is thoroughly effective, so that it should in all cases be employed in lieu of direct internal galvanisation.

The position of the electrodes should vary according to the seat of the affection. Where we have reason to believe that it is due to disease involving the *pedunculus cerebri*, one director connected with the negative pole should be placed to the back of the head, and another connected with the positive pole above the os pubis. The latter electrode should have a large surface. In cases of disease of the lumbar portion of the spinal cord, the negative pole is placed to the lower part of the lumbar spine, and the positive in the same position as above. Finally, in local paralysis of the bladder, we may either use the same arrangement of the electrodes as in spinal disease, or both directors may be placed above the os pubis.

How long should the application of the current be continued? and should it be intermittent or continuative? The intermittent application, according to my experience, is far superior to the continuative—a fact which is in perfect consonance with the results obtained by the same

method in other forms of paralysis. Fifty or sixty intermittences of the current are sufficient for one application. I am in the habit of leaving the positive pole *in situ*, and of removing the negative every three or four seconds, putting it on again immediately afterwards. The whole time of application in such cases, therefore, does not exceed three or four minutes.

The current used must have a certain tension; for, if it be feeble, no result is produced. I have in most cases used fifty or sixty cells of Daniell's or Smee's battery; but, in the cerebral form of the disease, less power may be employed.

I now proceed to narrate a few cases illustrative of the different varieties of paralysis of the bladder, and their treatment by the constant galvanic current.

**CASE I. Paralysis of the Bladder from Syphilitic Disease of the Pedunculus Cerebri.**—W. S., aged 29, unmarried, a clerk out of employment, was admitted as an out-patient at the Infirmary for Epilepsy and Paralysis, under my care, in April 1870. He had been in good health until three years ago, when he contracted a chancre, and had sore-throat and roseola about a month afterwards. He underwent a course of mercurial treatment, under the influence of which he apparently quite recovered. About Easter 1869, however, cerebral symptoms began to make their appearance. His memory became very bad; he frequently suffered from headache, and sensations of giddiness and dizziness; he felt irritable and desponding, and had some difficulty in expressing himself. At the same time, he entirely lost the relish for his work, and found sustained application impossible. He was now put on a course of iodide of potassium, under which he improved. Early in 1870, however, he had a fainting fit, and lost his speech for two days. He was now obliged to give up his employment altogether. About a month before I first saw him, he was suddenly affected with ptosis of the right eyelid; and, a few days after this had come on, with difficulty of micturition. This latter increased rapidly, so that he was only able, with great efforts, to pass about two tablespoonfuls of urine at a time. He was then, by his medical attendant, instructed in the use of the catheter, which he now introduced three times daily. He applied for relief at the Infirmary, chiefly with regard to a galvanic treatment of the ptosis, which troubled him more than his other ailments.

On examination, the patient appeared to be of sallow complexion, and spare habit. He had a childish and half-idiotic expression. He answered questions rationally, but in a sluggish and hesitating manner, and occasionally burst out laughing. The saliva was seen to dribble away from the corners of the mouth. There were complete ptosis of the right eyelid, and paralysis of the rectus internus muscle of the same eye. The sense of smell was diminished; the patient complained of nocturnal headaches and sleeplessness. The gait was rather staggering, but the patient could walk two or three miles without much fatigue. The heart and lungs were perfectly healthy. The tongue was fissured, and digestion was much impaired. The action of the bowels was torpid; and he never passed his urine now in the natural way, although he could by much straining pass a small quantity. The urine contained an enormous excess of phosphates, but was otherwise healthy. As the patient had taken large doses of iodide of potassium during the last twelve months, and his general nutrition was rapidly failing, he was put on iron and cod-liver oil; and galvanisation, by the constant current of Daniell's battery, of the paralysed muscles of the eye and eyelid, and of the bladder, in connexion with the medulla oblongata, was at the same time resorted to. There was soon considerable improvement perceptible in both affections. The patient passed about four ounces of urine in the natural way after the second application; after three more, he had entirely recovered the control over his bladder. The ptosis improved *pari passu*. Soon afterwards, he was lost sight of; but I heard lately that, although his general condition had become rather worse, and more especially his intellect was fast failing, there had been no return of the ptosis, nor of the paralysis of the bladder.

**CASE II. Hysterical Paralysis of the Bladder.**—A married lady, aged 32, of highly nervous constitution, who had lived much in the tropics, was sent to me by Dr. Frank in July 1870. She had been very delicate as a child, and her mother had died of phthisis. Family troubles thoroughly upset a system naturally predisposed to nervous disturbances, and in which only some powerful exciting cause was required for the full development of hysteria. Early in 1870, when she was under the care of Dr. Siordet, of Mentone, the patient had cataleptic seizures, and convulsive attacks resembling opisthotonos. She soon after lost her voice, and the power of walking and of voiding the urine. From March 6th, until the time she came under my care, the catheter had to be introduced twice daily. This was a cause of great annoyance, for it became necessary that the patient should, even in her travels, merely on account of this symptom, be constantly accompanied by a medical man

able to give relief to the bladder. The urine in this case was quite normal.

Galvanisation of the cervical sympathetic and the spinal cord was resorted to in this patient for producing a beneficial modification of the constitution of the nervous system. A current of fifty cells was also applied to the bladder on two several occasions (July 30th and 31st). After the first such application, the patient passed her urine in a feeble stream, and with a certain amount of pain and straining; after the second application, she could pass it freely, and had fully retained the power of doing so when I last heard of her, ten months later (May 1871).

**CASE III. Paralysis of the Bladder from Disease of the Lumbar Portion of the Spinal Cord.**—A gentleman, aged 46, married, of spare habit, and without regular occupation, was in his usual health in summer 1870, when he went for change of air to Blankenberghe, near Ostend. He took a most active part in all the gaieties which were going on there, and, amongst other things, danced all the dances every night at the casino, which he had not done for many years past. After this kind of life had gone on for about a month, he suddenly lost the power over the bladder, being altogether unable to void his urine, so that the use of the catheter became necessary. Soon after, he also lost to a great extent the power over the lower extremities, so that he was unable to walk for more than a few minutes at a time; and he began to suffer from obstinate constipation. Symptoms of catarrh of the bladder now likewise made their appearance. The patient consulted a number of eminent physicians and surgeons, both in Germany and England, who treated him with iron, nuxvomica, arsenic, ergot of rye, and various other medicines, but without beneficial result; and he came under my care in March 1871.

The symptoms had, on the whole, not varied much since their first appearance, but the catarrh of the bladder was now rather worse than before. The specific gravity of the urine was 1.025; it had a very feebly acid reaction, and readily turned ammoniacal on standing; it contained a large quantity of muco-pus. There were occasional attacks of great irritability of the bladder, attended with chilliness, chiefly at night. He introduced the catheter three times daily, and, when the bladder was irritable, as many as six times; and he never passed his urine in the natural way. Digestion was impaired, flatulency complained of, and the action of the bowels was sluggish and uncomfortable. The patient was in a most desponding state of mind, and almost despaired of recovery. He was treated with galvanisation of the lumbar spine, and of the bladder. After the second application, he could pass his urine freely by himself, and only introduced the catheter at bedtime, in order to make sure that the bladder was completely emptied. At first, he generally found about eight ounces of urine in the bladder; but, as the treatment proceeded, the quantity drawn off at night became reduced to two or three ounces, showing that the expulsive power of the viscus became more and more strengthened. The patient likewise underwent medicinal treatment for the catarrh of the bladder, and peripheral galvanisation was used for the lower extremities and the rectum; but it would be foreign to the purpose of this paper to enter at length into these matters. Suffice it to say that, when he discontinued the treatment in June last, the expulsive power of the bladder was all that could be desired; that the action of the bowels was much easier, and that he could walk some miles at a time without fatigue. The urine still contained muco-pus, but not nearly as much as before, and its reaction was now strongly acid.

The foregoing cases are sufficient to show the marked and rapidly beneficial effects which galvanisation of the bladder will produce in paralysis of that viscus, even if produced by constitutional causes, as in the first case, and by disease of the nervous centres, as in the last. If it be, at the same time, considered that the treatment is painless and devoid of inconvenience for the patient, it will, I hope, be conceded that a new and really valuable means for the relief of that troublesome affection has been added to our therapeutical store.

**DONATIONS, BEQUESTS, ETC.**—Mrs. F. K. H. N. has given £1,000 to the Royal Isle of Wight Infirmary, Ryde.—The Misses Steven, of Polmadie and Bellahouston, have, in accordance with the wishes of their brother, Moses Steven, expressed shortly before his death, distributed £2,000 between various charities, among which are £200 to the Glasgow Royal Infirmary, and £100 each to the Glasgow Western Infirmary, the West of Scotland Convalescent Home, the Glasgow Convalescent Homes, the Glasgow Royal Asylum for Lunatics, and the Glasgow Eye Infirmary.—The Malvern Rural Infirmary has received £100 under the will of Mr. Oliver Mason.—The Leicester Infirmary has received £500 under the will of the Rev. W. G. Sawyer.

## CLINICAL MEMORANDA.

### PUNCTURE OF THE INTESTINE FOR THE RELIEF OF TYMPANITES.

AMONG the various interesting communications which have appeared in recent numbers of the JOURNAL on "Punctures of the Colon for the Relief of Tympanites", no reference has been made to medical authorities who in the last century not only discussed the operation from a theoretical point of view, but successfully relieved by surgical interference the intense pain from which their patients suffered. I trust that a brief reference to these writers may not be devoid of interest to those members of our profession who are concerned in the revival of the operation.

It has occurred to me that the operation might have been first suggested by the practice, which was advocated by the older surgeons, of pricking with round or triangular needles the gut distended with air, in the course of the operation for hernia. Paré, Corneille de Soelingen, and Pierre Dionis, among others, recommended the practice. Heister, in his work on *Surgery* (Eng. ed., p. 74, 1750), suggests that in pneumatocele, or "hernia flatulenta", if ordinary remedies fail, the scrotum should be perforated with a trocar, and its contents thereby discharged, "which will demonstrate whether it was wind or water." In the same work, Heister expresses doubts of the success of the operation of paracentesis in tympanites. According to Sprengler, in his *Histoire de la Médecine*, vol. ix, p. 181, François de Paule Combalusier was the first who successfully employed the trocar in tympanites. (Combalusier, *Pneumatopathologia*, a French edition of which appeared in 1754, *Traité des Maladies Ventreuses*, traduit du Latin, par Jault, vol. ii, in 12.) Benjamin Bell, having observed that this operation was attended with but slight danger in the lower animals, advised that the intestine should be punctured in tympanites. Callisen, who used Petit's trocar, states that paracentesis may be useful as a palliative (*Syst. Chir. Med.*, Pars ii, p. 52). Charles Bell, in his *System of Operative Surgery*, vol. ii, p. 186, does not regard with much favour the practice of piercing the gut with the trocar in intestinal tympanites. C. B. Zang gives very precise directions for the performance of the operation. He plunges a long and fine trocar in the middle of a line drawn from the anterior extremity of the second left false rib to the anterior superior extremity of the ilium of the same side, to the depth of four or five inches. In this way the instrument strikes the descending colon without piercing the mesentery. (Zang's *Operat. Th.*, iii, p. 289.) Zang states that the operation is as devoid of danger as ordinary simple puncture, because, after the withdrawal of the cannula, the wound in the intestine does not exceed half a line in extent. In the *Dictionnaire de Médecine et de Chirurgie*, ed. 1835, L. Ch. Roche, in his article on "Tympanite", after recommending the ordinary remedies and attempts to draw off the gas with a syringe, states that, as a last resort, the abdominal walls may be punctured; and, although he considers the operation to be attended with grave danger, states that it has been practised a certain number of times with success. Among more modern works on surgery, Chelius gives similar instructions for the operation of paracentesis in distension of the alimentary canal with air, when the ailment is idiopathic, and not a symptom of any other disease. (South's edition, vol. ii, p. 495.) Olivier operated on twenty patients in Bolivia, South America, of whom eight recovered in three weeks; the others died, probably from not having been subjected to treatment till too late. The cause of the disease was attributed to overloading the stomach with half-cooked vegetable food, and drinking badly fermented liquid prepared from maize. (*Vide New Sydenham Society's Year-Book*, 1861; and Schmidt's *Fahrbücher*, vol. iii, p. 308.)

G. SYMES SAUNDERS, M.B., M.R.C.P.,  
Resident Physician, Devon County Asylum, Exminster.

### MALIGNANT DISEASE OF THE LUNGS SIMULATING PHTHISIS: ENCEPHALOID DEPOSITS IN THE KIDNEYS.

**PRIVATE JAMES C.**, aged 30, belonging to the 2nd Battalion Coldstream Guards, was in hospital for thirty-four days in 1860, for a simple venereal sore, which was followed by a bubo; and in 1868 for twenty-six days with bronchitis. He had been twelve years in the service. He was and always has been a strong, muscular-made man, and a good soldier.

He was admitted into hospital July 15th, 1870, for an attack of hæmoptysis, stating that he "spat up" a little blood on the 4th, and that on the night before admission he lost a pint in a similar way. He did not

look ill. The skin was cool. Temperature in the axilla 96.2. Pulse 68. Slight comparative dullness was detected below the right clavicle, with prolonged expiration. He had slight pain and an uneasy sensation in this side. The expectoration consisted of tenacious-looking "pellets," which were blood-stained and few in number. This condition continued without any decided change to August 5th, when, during the previous night, he had had a copious attack of hæmoptysis. His pulse continued remarkably quiet. There were now detected rather fine and numerous muco-crepitant râles below the right clavicle after deep inspiration or cough. He rapidly lost ground from this date, continuing to have more or less hæmoptysis, venous in character, and, when not blood-stained, purulent and frothy. There followed all the physical signs of rapid disorganisation of the right lung, with formation of a large cavity at its apex. On October 26th, he had retention of urine, which subsequently required relief by catheterism. The urine was always copious, notwithstanding profuse perspiration whenever he slept; it was free from albumen. The pulse was always slow, from 60 to 68, until he became hectic. The bowels were habitually constive. On October 31st, he suffered from abdominal pains, with fullness and tympanites. The tongue was dry and brown; the skin cold and dry. From this there was little change, and he died on November 3rd.

**NECROPSY.**—The body was much emaciated. There was a small tumour of the size of a pigeon's egg on the right side of the chest, surrounding the fifth rib, at its junction with its cartilage; another of similar size on the left side, around the centre of the fourth rib. Neither tumour was connected with the integuments. They consisted of soft, brain-like material. The ribs, where in connection with the tumours externally, were devoid of periosteum. The tumour on the right side protruded through the fourth and fifth intercostal spaces, the lung being indented by it, but non-adherent. The right lung, by its upper lobe, adhered firmly to the parietes, and was broken down in its removal, when a quantity of soft brain-like matter was taken away. Its upper lobe was destroyed, and lined with an irregular material of a similar character, intersected here and there by the remains of the vessels. Throughout the other two lobes were scattered aggregated masses of what at first sight appeared miliary tubercle, but they were more dense, harder, and heavier. The left lung was not adherent, and only contained deposits similar to those on the lower lobes of the right lung, but not to any great extent. The abdominal organs and mesenteric glands appeared healthy. The upper part of both kidneys had disappeared, and had been replaced by a globular mass, of about the size of the closed fist, surrounded by peritoneal covering, which gave it a white glistening appearance. On section, a distinct separation was seen between this mass and the lower part of the organs, which appeared normal. The diseased portion was dark, mulberry-coloured, and soft at its base, becoming lighter coloured, and more brain-like in consistence towards the circumference. Portions of the several diseased products were examined under the microscope, and presented well marked characters of malignant growth.

This case presents two or three points of interest. It had been diagnosed as one of hæmoptysis of a tubercular origin, and this was borne out throughout by the physical signs; while the slowness, or almost normal frequency of the pulse, was frequently noted as unusual in such cases. The kidneys found so extensively diseased had given rise to no symptom, either as to the quantity, or the character of their secretion.

JOHN W. TROTTER, Assistant-Surgeon, Coldstream Guards.

## THERAPEUTIC MEMORANDA.

### ABDOMINAL PUNCTURE IN TYMPANITES.

As the subject of tapping the intestine in tympanites is now being discussed, and a record of cases is being formed, I may perhaps be allowed to add one to the number.

In July 1869, I attended a lady with intestinal obstruction; and, after two or three weeks of treatment, Mr. Hilton came down from London and met me in consultation. As he did not consider the case suitable for calomel or other operative proceeding with a view to radical cure, I obtained his sanction to puncturing the bowel. This was done with a fine exploring trocar, a little to one side of the umbilicus, and with a considerable degree of immediate relief, air escaping, and the abdomen falling a good deal in size. The same proceeding was repeated about half a dozen times on successive days, and always with relief for some hours; but the amount of gas removable was always limited. No bad symptoms, however, were ever induced, though the patient ultimately succumbed to the disease.

Cheltenham.

T. MORLEY ROOKE, M.D. Lond.

### ABDOMINAL PUNCTURE IN TYMPANITES.

I WRITE to endorse the opinion of Dr. Braxton Hicks, that the credit of this operation must be given to that person who has placed it on a scientific basis and laid down rules for our guidance in its performance. The question of priority will probably never be determined; but I agree with your correspondents that it is by no means a novel procedure, for Mr. Stocker has often spoken to me of it as having been done at our hospital from the period of his earliest connexion with the institution. One case, which occurred twelve years ago, I well remember. Mr. Stocker called me up in the night to see a man just admitted for intestinal obstruction; and, as his sufferings were great, we put a trocar into his colon. It gave him great relief, and the operation was attended by no harm. The case was reported by Dr. Hilton Fagge in the *Guy's Hospital Reports* for 1869, p. 343.

SAMUEL WILKS.

77, Grosvenor Street, Grosvenor Square, W.

[M. Depaul communicated to the Surgical Society of Paris, on May 3rd and 10th, a case in which successive puncture of the transverse colon in a case of acute puerperal peritonitis, with vomiting and considerable tympanites, gave great relief, the patient ultimately recovering. (*L'Union Médicale*, July 27th and 29th.) M. Fonnagrives has communicated to the Academy of Medicine a paper (August 12) in which he cites eighty four cases where puncture of the intestines has been practised for tympanites. He recommends the operation in severe cases, as one which gives great relief, and is not particularly dangerous. Other speakers expressed their confidence in the operation. ED. B. M. J.]

### VACCINATION OF NÆVI.

IN the last impression of the JOURNAL I read a letter from Mr. G. F. Hodgson of Brighton on Mr. Ellis's mode of vaccination by blister. I have had no experience of its value in ordinary vaccination, but have for years been in the habit of using liquid blister for abrading the surface in the treatment of nævi, where circumstances have permitted me to adopt vaccination as a means of cure. The difficulty of applying the lymph satisfactorily, owing to the free bleeding which is apt to follow puncture of a nævus, induced me to try exposing the absorbing surface by blistering it. I found the plan very satisfactory; and whenever a suitable case has since come under my notice, ordinary vaccination not having been practised, I operate in this way, and have invariably been successful.

The largest nævus which I have removed by this method was nearly an inch in diameter, very prominent, and situated on the scalp. Ligature being inadmissible, and pressure having been applied assiduously for many weeks without the slightest diminution in the size of the tumour, Sir James Paget advised its destruction by nitric acid. Before carrying out these directions, I thought I would try the effect of blister-vaccination, but, from the raised fleshy nature of the nævus, was not very confident of success. The result, however, was complete obliteration, the scab separating in about ten weeks. Vaccination in this case had not been done at the usual time, in consequence of the child's extremely delicate condition.

E. F. WESRON,

Surgeon to the Stafford County Infirmary, etc.

Stafford, November 14th, 1871.

### SULPHUROUS ACID IN SMALL-POX.

I AM glad to be able to corroborate the statement of Dr. Hjaltelin as to the value of sulphurous acid administered internally in small-pox. The number of cases which have been under my care have only been a few more than those treated by Dr. Hjaltelin, and I should have thought them too few in number to warrant remark by themselves. As, however, they have all been treated with sulphurous acid and have all done well, they give an evidence in favour of Dr. Hjaltelin's treatment which is worth recording. Several of my cases were confluent, in persons who had not been vaccinated; others were semi-confluent, and others modified. They were all treated with sulphurous acid and water in varying doses; and I believe that the eruptive fever was checked, the secondary fever rendered less dangerous, and the period of convalescence shortened. I have had sulphur burned in all the sick rooms; for, as a germicide, there is, in my opinion, nothing more potent. Sprinkling carbolic acid about a room seems to me worthless. What is wanted is a gaseous substance that will fill the room, enter all the cracks and crannies, and touch the ceiling as well as the floor. If carbolic acid be preferred, the best way to use it is to sprinkle it upon a shovelful of hot cinders. I ought to say that, as "parish doctor," I have seen many other cases than my own, and the result has been renewed faith in sulphurous acid.

R. T. MANSON, L.R.C.P. Ed., M.R.C.S.E., Howden.

# REPORTS

OF

## MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

### ST. THOMAS'S HOSPITAL.

#### EXTROVERSION OF THE BLADDER.

(Under the care of Mr. SYDNEY JONES.)

ON Wednesday, October 25th, Mr. Sydney Jones introduced into the operating theatre a patient suffering from this malformation. In the treatment, his object had been to divert all the urine into the rectum (as suggested by a case of Mr. Simon's), and to close the anterior orifice of the ureter. He had already made a communication, of about half an inch in extent, between each ureter and the rectum, by introducing a silk loop through each ureter, and gradually tightening it by a Graefe's tourniquet in the rectum. There was abundant evidence, before and during the operation, of the sphincter ani being able to control the escape of urine. On the day of operation, as much at least as two ounces escaped as soon as the sphincter was relaxed by the introduction of the finger into the rectum.

Mr. Sydney Jones now proceeded to attempt closure of the anterior orifice of the ureter. Each ureter was drawn forward for about an inch; a director being introduced, the galvanic cautery was applied, so as to destroy the mucous membrane. Two small clamps were subsequently fixed so as to compress the deepest point of each ureter.

Mr. Sydney Jones remarked that, in this case, there had been abundant evidence of the power of the rectum and sphincter to retain urine. It remained to be seen if the formation of a cloaca, such as here aimed at, would prove as serviceable as, or more serviceable than, the receptacle usually made in front of the extroverted bladder.

### CHARING CROSS HOSPITAL.

#### EXTROVERSION OF THE BLADDER.

(Under the care of Mr. BELLAMY.)

THE operation for extroverted bladder, introduced to the notice of the profession by Dr. Ayres of New York in 1859, and since practised by Pancoast, Holmes, Wood, and others, was performed in Charing Cross Hospital on the 13th of July last, on a young man, by Mr. Bellamy. Unfortunately, however, the superior abdominal flap sloughed away in consequence of the patient's incessant coughing from bronchitis after the operation. The lateral flaps retained their vascularity, but became two cutaneous nodules, like walnuts, growing from the lower part of the groin on each side, the left larger than the right. On November 4th, Mr. Bellamy tried a second operation, in which he hopes to be more successful. The right flap he carefully dissected from the subcutaneous tissue after making an incision round the outer, upper, and inner margins. The left flap, which was very thick, he divided, and dissected the inner half as he had done the right flap. The three were then carefully drawn over the mucous surface of the bladder, and united by a suture. Of course there is now no possibility of obtaining an abdominal flap; yet some relief will be afforded to the patient if this operation be successful.

### ST. BARTHOLOMEW'S HOSPITAL.

OPERATIONS, SATURDAY, NOVEMBER 11, 1871.

*Amputation of the Leg at its Lower Third.*—This patient was a most powerful man, having extraordinary muscular development throughout the body, particularly of the arms; yet the circulation in his left leg was exceedingly sluggish, and the limb always cold. He met with an accident on an Indian railway some years ago, his foot being crushed. Amputation was performed, but the flap was scanty, and the scar was never a good one. Latterly the stump became such a source of annoyance to him that he determined to come into the hospital, and, if necessary submit to a second operation. Various means were tried to make the stump heal, among which was skin-grafting. But on account of the sluggish circulation in the limb, and the unhealthy granulations on the wound, they did not succeed. Mr. Callender operated, making a large and full back flap, and placing the leg on a back splint to insure rest,

and with abundance of cotton wool to insure warmth. There were no vessels of consequence to tie, these having been completely obliterated after the former operation. The singularity of the case was the extreme coldness of the damaged leg, and the power of the general system. Seven men hardly sufficed to keep the man on the table during the excitement of the chloroform.

*Recurrent Fibroid Tumour on the Back.*—This patient had a tumour as large as a child's head removed from his back less than three years ago. The tumour then appeared to be quite enucleated; but the disease has several times returned, and, on the present occasion, the operation was the fifth that had been performed on the same part for its removal. The tumours have always grown with remarkable rapidity, a few months bringing them to the size of a cocoa nut.

*Extensive Disease between the Os Calcis and Astragalus.*—This patient was operated on by Mr. T. Smith. After making a free incision on both sides of the foot, he gouged out a quantity of diseased bone, and ran a seton through from side to side. He found the rose-headed drill of great service in running through the articulation. The patient's foot was very much swollen, and it was thought that the ankle-joint was involved. After the operation, however, the disease was found to be confined between the os calcis and astragalus.

### SOUTH DEVON AND EAST CORNWALL HOSPITAL.

#### CASE OF VESICO-VAGINAL FISTULA.

(Under the care of Mr. SQUARE.)

S. H., a stout, somewhat florid, though not healthy-looking, woman, of hysterical temperament, was admitted into the medical wards on June 28th, 1870, suffering from constant escape of urine. She was thirty years of age, had been married ten years, and had had four children, all living. All her labours had been difficult; the last, in August 1869, particularly so, lasting thirty-six hours. Directly afterwards she noticed the continuous escape of urine, which was attributed to weakness. For three months she was confined to bed; and, up to the date of admission, had been quite unable to work, partly from general debility, but chiefly from the inability to retain her urine. She was ordered a mixture of iron, strychnine, and spirit of chloroform, and in about a month her general health very much improved; but, as the escape of urine continued quite unaltered, an examination was made by Mr. Square, who found that there was a fistulous communication between the vagina and bladder on the right side of the median line, about an inch and a half in length when the parts were drawn down by a hook.

On August 30th, the edges of the fistula, being held firmly, were pared with a fine straight knife. Six wire interrupted sutures were then introduced, by means of a curved tubular needle. The sutures were then merely twisted close up, by means of an instrument terminating in a doubly perforated ball, no quills or buttons being used. The patient was placed on her side in bed, and a short metal catheter, with an S-like curve, having attached to it an India-rubber-tube, was introduced, so that the extremity of the curve projected forward over the pubis, whilst the tube passed backwards to a vessel at the side of the bed. The catheter and tube were removed twice a day, to be cleared of mucus; but, with that exception, they were kept constantly in for a fortnight. A pill, containing three-quarters of a grain of opium, was given every four hours; and, to check the vomiting caused by the chloroform, ice was ordered with good effect. At first the vomiting was severe, and sufficient to cause some anxiety as to the endurance of the stitches. She had for some time milk-diet and fish. The urine was normal, and came away *guttatim*, thus keeping the bladder empty; and, having no cause for contraction or spasm, the bowels after the second day were open regularly. There was no sickness after the first day. The opium was gradually reduced; and on September 9th she was ordered a mixture of quinine and acid and a chop. Not the slightest leakage of urine into the bed had been detected. On September 13th, a fortnight from the operation, the catheter and tube were removed, and for the next few days an ordinary catheter was introduced every two hours. At first she had some difficulty in waiting so long, but that gradually passed off; the catheter was introduced less and less frequently, and on September 20th the urine was allowed to pass naturally. Her progress with regard to her general health was very slow, and once or twice she took cold, which retarded it still more. On October 2nd, the sutures were removed. She was kept in on account of her general health until November 9th, when she was discharged.

The chief points of interest in this case seem to be the complete success of the ordinary interrupted sutures, and the advantage of not allowing any urine to collect in the bladder, and by that precaution avoiding contraction and spasm.

THE Subscriptions to the Association for the year 1871 became due in advance on January 1st. All which are not already paid, should be forwarded to the General Secretary, Mr. T. Watkin Williams, 13, New Hall Street, Birmingham; or to the Secretaries of Branches.

## BRITISH MEDICAL JOURNAL.

SATURDAY, NOVEMBER 18TH, 1871.

### REGINA v. KELLY.

THE trial of Kelly for the murder of Talbot has ended in an acquittal. With the juridical and political aspects of the trial we have no professional concern. With the decision of the judges as to the point of law raised, we are chiefly interested to observe that the Lord Chief Baron finally laid down very distinctly what has always been understood by our profession as the rule of law—that a surgeon was bound to bring to his task generally competent skill and *bona fides* with a view to effect cure; and that it was beyond the custom and province of courts of law, in case of alleged murder, to enter into a minute technical discussion of the details of treatment, when it had satisfied itself that the surgeon was a competent and qualified person, acting to the best of his knowledge and in an upright intention to effect the cure of his patient, or to give him a possible chance of life. We can but join in the wish which has been expressed in the most competent quarters, that this just ruling had been acted upon more decidedly in the earlier part of the case. It is, of course, difficult for us to say what expedients are not justifiable for an advocate to whom his client's hope of life is entrusted. But it is impossible not to feel acutely the gross injustice which Mr. Butt's line of defence in this case inflicted on an able surgeon, who fulfilled with earnestness, skill, and devotion, a most delicate and important duty. There is not, we believe, the least difference of opinion amongst surgeons, that Mr. Stokes, whose skill and attainments have made for him a reputation which extends far beyond the limits of this country, fulfilled in this case to a nicety all the duties of his office. He would have been highly blameworthy, had he failed to do all that art could suggest to give a last despairing chance of life to a man whose injuries, left untended, must have been fatal. In such a case, little short of a miracle could have saved the patient. But we record even this week a case in which, a bullet having been lodged for three weeks deeply in the substance of the brain, and having been sought for by trephining, and removed after washing away the diffuent portion of brain-substance through which it had passed, the patient recovered, and was restored to sound health. As Dr. Howard, the narrator, says, "the will of Providence alone can be offered in explanation of the recovery of the patient"; but it is to that high arbitrament that the surgeon must leave the issues of his efforts in cases so desperate. He would be culpable, indeed, to shrink from the last efforts which science tells him can afford a desperate chance to a patient wounded through the base of the brain or the upper part of the spine.

Such a fiery ordeal of vituperative depreciation as Mr. Stokes has been called upon to pass through might well induce the boldest surgeon to hesitate before he interfered, in another such case as that of Kelly, with what would otherwise be the inevitable course of nature. But we have confidence that they will not be deterred by any considerations from the performance of their duty under such responsible circumstances. The character and skill of Mr. Stokes have been amply vindicated by the issue; and we feel assured that he will not ultimately have any reason to regret that he did his duty by his patient.

### SUPERANNUATION OF POOR-LAW MEDICAL OFFICERS.

OUR readers are acquainted with the details of the Poor-law Medical Officers' Superannuation Act (1870), which declares in its preamble that "it is expedient that provision should be made to enable superannuation allowances to be granted to medical officers of unions, districts, and parishes, in England and Wales, who become disabled, either by infirmity or age, to discharge the duties of their office." This Act was framed on the Irish Act, which has now been carried out during its brief period of existence in upwards of thirty cases. Under the circumstances above stated, the Act authorises the guardians to make an annual superannuation allowance, which is usually calculated at two-thirds of the prior income; and defines the fund from which it will be made, as well as the form of certificate necessary for the medical officer to claim the allowance. Recently Mr. Grubb of Warminster applied to his guardians to apply the Act in his case: the circumstances are precisely those contemplated by the law. He had filled the office with credit, and satisfaction to all, during twenty-seven years; he is now retiring, suffering from infirmity, his health having broken down during the course of his arduous services. Some time since, while in the discharge of his duty, he met with an accident, fracturing his thigh. His application to his Board has been met by the following resolution.

"Resolved,—That this Board are fully sensible of the conscientious discharge by Mr. Grubb of his duties as their medical officer during the last twenty-seven years. That they have given full consideration to his application for a retiring pension, but are sorry that they are unable to entertain it, lest they should establish a precedent, which they are unwilling to do."

We earnestly hope that the Board, who are evidently acting under an unjust and mistaken impression, will reconsider the matter. The principle is settled by the Act of Parliament, which declares that it is expedient that, under such circumstances as they admit to exist, a pension shall be granted. Thirty precedents already exist under the Irish law, and to say that they do not mean to form a precedent is a peculiar hardship and injustice. The refusal to apply the law is in direct contradiction to the expressed intention of the legislature; and, even from a legal point of view, it may very much be doubted whether Mr. Grubb might not enforce the Act against them. The permissive character of the Act is evidently intended to give the guardians power to refuse the allowance to an undeserving officer, or one who has not satisfactorily performed his duty. This, they fully admit, is not the case with Mr. Grubb: and, entirely believing that the guardians of Warminster have been led into an act of gross injustice by a misapprehension of their position and duties in the decision, we submit the matter confidently to their own sense of right and justice for redress.

We shall only add one word. The Legislature, in placing in their hands a permissive power, which enables them to hold the greater control over their officers, by having the means to punish undeserving officers by withholding a pension, by no means contemplated that the guardians should flatly refuse to carry out the provisions of the Act in the express circumstances which are declared to render it expedient. This is to nullify legislation; to contravene the intention of the Parliament, which is expressed with peculiar clearness in the preamble; and to desert their first and most apparent duties as repositories of a parliamentary power, and public functionaries acting under a legislative authority. To refuse to carry out an Act of Parliament, because to do so would create a precedent, is a position of dangerous absurdity, of which a little reflection will show to the Warminster guardians all the enormity. Perseverance in such a course could only have one issue. The attention of Parliament being called, as of course it would be, to so flat a contradiction of its declared will and intention, it would become necessary, as it became necessary in the case of the education of Catholic children, to take out of the hands of the guardians a power which they deliberately abused. As friends of local self-government we always deplore instances of local perversity.

This Act was passed in the interests of the poor, so that, when a medical man became incapacitated from adequately fulfilling his duty to them, his poverty should not fight with his will in inducing him to hold on to office. The guardians are guardians of the poor as well as of the rates. It is contrary to the public welfare, no less than to the declared intention of the Legislature, that superannuation allowances should be withheld from medical officers of long service, whom proved and certified infirmity incapacitates from the adequate performance of their duties, and when they ought and wish to retire. This very board, we may observe, is now pensioning its relieving officer.

#### ADULTERATION OF DRUGS.

THE adulteration of drugs is probably not carried on in this country to the same extent as in America, but it certainly is to a large extent; and a report recently presented to the Pharmaceutical Conference at St. Louis by Mr. J. H. Remington of Philadelphia exposes some of the tricks of the trade, to which it may not be unprofitable to direct the attention of our readers.

After some introductory remarks, he proceeded to say that, of all substances, powders were probably the most liable to adulteration; and that principally in consequence of the difficulty of detection. He had been informed of several wholesale drug-houses where rooms were set apart for the purpose of mixing powders; and another case where there was a regularly organised adulterating department, with a foreman—of no doubt large experience—to superintend this special branch. All sorts of cheap substances were used in this department of industry, the object being to imitate as nearly as possible the colour and general appearance of the genuine article: flour, starch, terra alba, woody fibre, sawdust, musty ship-biscuits, were all in demand for this purpose. Spices, on account of their widely extended use, are of all powders most largely adulterated; and some startling revelations might be made if a spice-miller could be persuaded to disgorge his ill-gotten knowledge. The only safe way to get pure powdered drugs is, according to Mr. Remington, to pay a good price, and buy from conscientious persons who are above suspicion. Cochineal is adulterated with sulphate of barytes, a heavy white powder, which, when shaken with the insects, lodges in the wrinkles and crevices on the surface of the body. The weight is thus increased sometimes from 15 to 25 per cent. Balsam of copaiba is often mixed, and sometimes is found entirely fictitious, being composed of a mixture of castor-oil, resin, and oil of copaiba. Powdered ipecacuanha is sometimes so adulterated and weakened that tartar emetic is necessary to strengthen it. Oil of lemon has been met with, mixed with 30 per cent. of fixed oil. Powdered opium is often mixed with powdered extract of liquorice. In fact, some dealers uniformly send to the grinders a certain proportion of liquorice with the opium, so that they may be ground together. Powdered rhubarb is frequently adulterated with turmeric. Sometimes senega-root is mixed with cypripedium. Castile soap frequently contains an undue proportion of water. It has been met with containing as much as 30 per cent. Acetic acid is also mixed with water, acidulated with dilute sulphuric acid. Subnitrate of bismuth has been found mixed with phosphate of lime to the extent of 20 per cent., and citrate of iron and quinine adulterated with citrate of ammonia, and containing less quinine than called for, 10 or 15 per cent. instead of 25 per cent. Quinine itself is frequently met with mixed with cinchona, muriate of cinchona, and salicine. Santonine has been found adulterated with small particles of mica and cream of tartar, and cream of tartar frequently mixed with tartar emetic. Cream of tartar is grossly adulterated; the terms strictly pure, pure No. 1 and No. 2, being used to indicate varying proportions of cream of tartar and terra alba: the latter material is largely imported for the express purpose of adulterating, the importations amounting to many tons annually. Chloroform is sometimes diluted with alcohol, and iodide of potassium in crystals is mixed with bromide, and occasionally with bicarbonate of potash. Solid extracts are also much adulterated. In the manufacture of syrup, a

considerable portion of the sugar is replaced by glucose, especially in making fruit-syrups.

In the discussion which followed, Professor Marcoe of Boston referred to white Castile soap of handsome appearance which he had met with containing 20 per cent. of steatite, which could be detected by its insolubility; and Mr. W. Saunders, of London, Ontario, to a quantity of oil of peppermint, which had been submitted to him for examination, containing 25 per cent. of castor-oil.

THE Birmingham Hospital for Women is to be opened for the reception of patients on the first Monday in December.

A CORRESPONDENT informs us that a provident dispensary has been recently opened in Mansfield. This is the second time the dispensary has been opened, the former having failed some years ago.

HER Majesty's Government, on the recommendation of Mr. Gladstone, has been pleased to grant from the Royal Bounty the sum of £300 to the children of Dr. Livingstone.

THE professorial speeches, and the expression of their sympathies by the students, at the reopening of the School of Medicine in Paris, were very republican in character.

FROM an account of the water-supply and soil of the town of Zürich, we learn (*Der Naturforscher*, August) that, in the cholera epidemics of 1855 and 1867, no confirmation could be found of Pettenkofer's theory with respect to the connexion of cholera and subsoil water.

DR. LIEBERMEISTER of Basle has been appointed Professor of Pathology and Therapeutics at Tübingen, in the room of the late Dr. von Niemeyer; and has been succeeded in his post as Professor of Medicine by Dr. Immermann of Erlangen.

THE Shoreditch local authorities persist in their determination to sell the timber of their probably infected small-pox shed; and Mr. Shaw Stewart has proposed, therefore, that the Asylum Board Managers shall buy and destroy it. The sum necessary is £27 : 10.

THE steamer *Franklin*, from Stettin, has arrived in New York. On her voyage, forty-one deaths from cholera occurred on board.—The official news report from the Persian Gulf states that on the Arabian coast "many deaths from cholera have taken place, and all the people are engaged in interring their friends."—Cholera is again becoming very fatal in Constantinople.

A VERY remarkable collection of medicinal and other drugs, says *Nature*, has been brought together in the Exhibition of Natural Industry of the United States of Columbia or New Granada in the city of Bogota. Among febrifuges, it includes the yellow quina of Zaragoza and the Sarpolata, which is considered more effective even than quina of dye-plants.

DR. CZERNY, senior assistant to Professor Billroth of Vienna, has accepted an appointment to the Professorship of Practical Surgery at Freiburg. The *Wiener Medizin. Wochenschrift* remarks that this is the first appointment of an Austrian to a German university which has been made for some time; and regards the fact as evidence of the high reputation possessed by the Vienna school of medicine.

AT the recent Pass Examinations for the diploma of membership of the Royal College of Surgeons, ninety-seven candidates presented themselves; namely, forty-six for the double examination on Surgical Anatomy and the Principles and Practice of Surgery, and also the Principles and Practice of Medicine; nineteen on the first part only; three on Medicine, having previously passed in Surgery; and twenty-nine who, having passed a Medical examination elsewhere, were only examined on the Surgical portion.

DR. C. J. B. ALDIS proposes that the plan of employing dust-boxes, daily removed, should be followed throughout the metropolis. It has been adopted by the City of London, and is practised in some country towns and in many places abroad.

THE deputy coroner for East Middlesex (Mr. Richards) and jury, at an inquest a few days since, subscribed 8s. 6d. to summon Dr. von Seydewitz of the East London Hospital, for performing a *post mortem* examination without leave and "robbing the body" of the heart.

THE people of Hampstead are still anxious to have the Small-pox Hospital removed, and are frightening each other with cock-and-bull stories about the infection which it has spread. It is to their persistence in spreading these groundless alarms that they chiefly owe the depreciation of property of which they complain. Mr. Stansfeld has requested them to say precisely "how much" they are afraid of it, and to make a definite written proposition.

MR. CORDY BURROWS has, by the special favour of his fellow-townsmen, been re-elected for the third time (and out of ordinary course) as mayor of Brighton during the ensuing year. The British Association will meet during the year at Brighton, and the compliment is therefore the more marked. He inaugurated his year of office by a banquet, to which between 400 and 500 guests sat down. —We learn with pleasure that Mr. T. L. Gregson, surgeon, of Newcastle-on-Tyne, has been elected Mayor of that town. At the time of the annual meeting of the Association there in 1870, Mr. Gregson was Sheriff, and took an active part in the hospitable reception which was given to the visitors on that occasion.

#### MAKING THE MOST OF A MISFORTUNE.

A MAN is just now making the round of the London hospitals, exhibiting a curious malformation, and selling photographs of it. He has been born with two hands and lower arms on one side, and these are so joined that the fingers of the one act in opposition to the fingers of the other—perform, in fact, the function of the thumb in normal cases. We can only hope that his sale of the photographs to the curious student will repay his trouble, and compensate in some measure for the annoyance of his malformation.

#### FREE TRADE IN POISONS.

THE Croydon magistrates gave last week a very strange decision in the case of a chemist named Harrington, who, it was proved, had sold oxalic acid contrary to the provision of the Pharmacy Act, without labelling it, or marking it with the name and address of the seller. For this gross and dangerous breach of an Act passed in the essential interests of the public safety, the magistrates imposed on the offender a penalty of sixpence, saddling the complainant with the cost. A more senseless and dangerous decision we have not had occasion to observe.

#### DIABETES, LACTIC ACID, AND RHEUMATISM.

EARLY in the year, we published a communication from our correspondent in Naples, containing an account of Dr. Cantani's views on the treatment of diabetes by lactic acid. We believe this treatment has since been tried by several observers in this country. Dr. Balthazar Foster, of Birmingham, tried it very carefully very soon after Cantani's views were made known; and at the last meeting of the Birmingham and Midland Counties Branch, he read a paper containing the results of his experiments. The effect of the lactic acid treatment was illustrated by a diagram, in which the variations in the amount of sugar, in the quantity and specific gravity of the urine, and in the body weight of the patient, were represented graphically. Dr. Foster's observations tend to show that lactic acid has some influence in diminishing the sugar, though less than Cantani reported. The most interesting fact, however, in Dr. Foster's paper was the development of acute articular rheumatism during the lactic acid treatment; this was repeatedly observed in one case. We hope to lay these observations before our readers very shortly, as well as Dr. Foster's general experience on the treatment of diabetes.

#### BULLET IN THE BRAIN.

THE surgical history of the case of Talbot, developed at the recent trial, gives a special interest to an extremely remarkable case recorded by Dr. Howard of New York, in the recent number of the *American Journal of Medical Science*. The patient was a soldier in the 44th Indiana Infantry. The bullet entered the skull at a great distance from the point where it penetrated the scalp: it made at first a sort of trap-door fracture, and gave rise to but few symptoms. When symptoms threatening death occurred two weeks afterwards, its presence in the brain was diagnosed by a hair which was found sticking out of the aperture in the bone, and which the bullet had evidently carried with it. The skull was trephined; the ball was found deeply buried in the brain, and was removed two weeks after the injury. The patient made a complete recovery, and subsequently enjoyed robust health, having returned to duty, and served in the cavalry.

#### WELL-MERITED HONOURS.

By decree of 11th of July last, Dr. Rose Cormack, our correspondent in Paris, received from the French Government the Cross of Chevalier of the Legion of Honour. On the 24th of the same month, M. Jules Favre forwarded a copy of the decree and the insignia of the Order, accompanied by the following very gratifying letter.

"Paris, le 24 Juillet, 1871.

"Monsieur,—J'ai l'honneur de vous annoncer que le Chef du Pouvoir Exécutif de la République vient, sur ma proposition, de vous conférer la Croix de Chevalier de la Légion d'Honneur. Je me félicite d'avoir été à même de faire connaître au Président du Conseil le savoir et le dévouement avec lesquels vous avez donné vos soins aux blessés français recueillis dans l'ambulance anglaise de la rue d'Aguesseau. Vous vous êtes montré un digne collaborateur de Sir Richard Wallace: et le gouvernement français s'est plu à le reconnaître.

"Recevez, monsieur, avec mes félicitations les assurances de mes sentiments les plus distingués.

"Le Ministre des Affaires Etrangères, JULES FAVRE.

"M. le Docteur J. R. Cormack, 7, rue d'Aguesseau."

Along with the above, the following document (the usual certificate) was received by Dr. Cormack.

"République Française.—Ordre National de la Légion d'Honneur. —Le Grand Chancelier de l'Ordre National de la Légion d'Honneur, certifie que, par arrêté du onze Juillet, mil huit cent soixante onze, M. Cormack, médecin anglais, a été nommé Chevalier de la Légion d'Honneur, pour prendre rang du même jour.

"VINOY.

"Versailles, le 15 Juillet, 1871."

Dr. Cormack has also received the war medal and the cross of the Société Française de Secours aux Blessés. To the congratulations on these honours we wish to add our own. Dr. Cormack showed a remarkable amount of devotion, courage, and skill, throughout both sieges of Paris. He kept bravely to his post, and never ceased to fulfil all the duties of a citizen, a philanthropist, and a physician.

#### ANOTHER LADY-DOCTOR.

MISS SUSAN DIMOCK, a young American lady, has just graduated with distinction in medicine, surgery, and obstetrics, at the University of Zurich.

#### PRECAUTIONS AGAINST CHOLERA.

THE London College of Physicians have recently shown a wise but ominous foresight in appointing a Committee during the quiet winter months to consider what general public recommendations they can properly authorise, in the present state of knowledge, for the personal guidance of those who may be threatened or attacked with cholera. This Committee will shortly issue its report. Just now we are free from the epidemic influence, and possibly, therefore, too little alive to the prospective perils of the next warm season. But let the Local Boards of Health and sanitary authorities throughout the country take example from the London College. During the cold season, the low temperature arrests the extension of the disease; it does not extinguish it, or destroy the power of subsequent activity in the particles of contagion, which await the return of a higher temperature. The pois ons

of the Deltas seem all to follow this law—the yellow fever which is born in the Delta of the Mississippi, the plague born in the Delta of the Nile, and the cholera born in the Delta of the Ganges. But woe comes to those who assume that this hybernation implies entire extinction of activity. The Russian experience of 1847 is still at hand to teach us. The epidemic which had become generalised at the close of 1847 appeared to be brought to an end by the severe winter of 1848. From the 1st of February, 1848, there were no more cholera-deaths. Then every one said, "The outbreak is over." But the months of April and May of that year cruelly dispelled these illusions. Cholera reappeared every where in its haunts of the previous year, and spread with frightful rapidity throughout the vast territory of the Russian empire. The number of deaths in all the Russias in the month of July, 1848, is stated by Dr. Chasseaud of Smyrna, in his prize essay just published at Constantinople, to have amounted to eighty thousand weekly. The existing state of things at Constantinople, and the history of the German cholera ship which has just reached New York, shew that our present sense of security is based upon data which are merely local and superficial.

#### MORTALITY AMONG CHILDREN IN VIENNA.

THE great amount of mortality among foundlings and nurse-children in Vienna has aroused the attention of the city authorities, who have instituted an inquiry into the subject. In consequence of this, the *Stadphysicus* has made the following suggestions. 1. The Common Council shall undertake the chief inspection of children put out to nurse, in the same way as it already does in the case of orphans maintained at the public charge. 2. In order to carry out this object, it shall authorise the Children's Friends' Society to inspect the nurse-children in Vienna. 3. It shall supply the society with a place for meeting and for keeping its records, on condition that it furnishes regular reports to the magistrate. 4. The Common Council shall, as far as possible, contribute to the support of this society as well as of the fund established by Dr. Heldinger. 5. The Council shall provide that nurse-children shall be received only under a police licence, and that the neglect to give information about them shall be severely punished; and shall provide a place for keeping a register of the names of all foundlings and nurse-children. 6. In order that there may be a sufficient amount of public medical aid for the children, small districts shall be formed, to each of which a physician shall be appointed, who shall be under the direction of the General Sanitary Administration.

#### OVARIOTOMY ON A CHILD.

DR. J. EWING MEARS records, in the *Philadelphia Medical Times*, Nov. 1, a case in which ovariectomy was successfully performed on a child six years and eight months old, for the removal of a dermoid cyst of the right ovary, containing three pints of fluid, with solid contents—an irregularly shaped osseous mass, some hair, and fatty matter. Dr. Atlee has operated on a girl aged 16; Mr. Baker Brown records ovariectomy in a patient aged 13; and in the *Edinburgh Medical Journal* for November 1870 is the report of a successful ovariectomy by M. Jouon of Nantes, the patient being aged 12. The patient of Dr. Mears appears to be the youngest on record.

#### VEGETABLE SOURCE OF CARBOLIC ACID.

MR. J. BROUGHTON, quinologist to the Indian Government, states (*Pharmaceutical Journal*, Oct. 7th, 1871) that from the essential oil of a very common hill-plant—the *Andromeda Leschenaultii*, identified as methyl-salicylic acid, and almost identical with the Canadian oil of winter green—he finds that a very pure carbohc acid may be prepared at from five to seven shillings per pound in that country. The plant grows in inexhaustible abundance on the Neilgherries; and it appears to him worthy of record that, should circumstances render the supply of the English product difficult or uncertain, as in the case of war, or the English price increase, a practically inexhaustible source exists in India, from which this indispensable substance, in its purest state, can be obtained at a slight enhancement of the present price.

#### THE SUPPORT OF HOSPITALS BY WORKING MEN.

OUR Leeds correspondent writes:—A bazaar in aid of the funds of the new hospital at Rotherham was opened on the 9th instant by Earl Fitzwilliam. In the address, his lordship referred to a statement which he had received from Dr. Shearman, from which it appears that, during the past year, forty-three accidents sent from Rotherham were admitted into the Sheffield Infirmary—a distance of six or seven miles. It was further stated that the proprietors of the Parkgate Ironworks have made a legal claim upon their workmen to contribute a penny a week from their wages towards the support of the Rotherham Hospital. "The subscriptions of the Parkgate workmen will amount to £430 *per annum*; and Dr. Shearman calculates that, if every workman in the neighbourhood would do likewise, the sum of about £3,000 a year would be realised; and that sum would be amply sufficient to keep this institution permanently going and prospering."

#### THE HISTORY OF MEDICINE.

M. DAREMBERG has inaugurated, at the School of Medicine in Paris, the new course of the History of Medicine, founded by a legacy of M. Champotran. Tracing the difference between the inductive school of Hippocrates and the deductive system of Cnidos, he declared that the deductive, or *à priori* method, will always be fatal to science; and that the inductive or experimental method is the only true system, to which science owes its progress, and that its application to medicine will be the lasting glory of the Hippocratic school.

#### SPURIOUS URTICARIA.

M. GARNIER, in commenting, in *L'Union Médicale*, Nov. 14th, upon the observations of Dr. Sieveking, in past numbers of this JOURNAL, on the Urticaria produced by Santonine, observes that he speaks of the roseolar eruption produced by mussels and tunny fish, and other food more or less deteriorated, as being identical with that following the use of copaiba. Dr. Garnier has observed that they differ, in that in the former cases there are always gastro-intestinal disturbance, nausea, and vomiting, which, he asserts, are not observed to accompany the roseola of copaiba.

#### LESSONS FROM INDIA.

THE Secretary of State for India has issued a valuable blue-book, containing the annual report on measures adopted for sanitary improvements in India from June 1870 to June 1871, together with abstracts of sanitary reports for 1869, forwarded from Bengal, Madras, and Bombay. This blue-book summarises, in a highly interesting form, the annual reports of local commissioners; and contains large data concerning the rise and progress of cholera epidemics, the direct influence of sanitary works in lowering death-rates, and many accessory subjects. In an able review by Dr. Cunningham of the local cholera reports, he concludes, from stated data, that the water cholera theory, although warmly espoused by some of the Presidency sanitary officers, and especially Dr. de Renzy, is not fully supported by the great mass of facts collected. We have already referred to the histological report by Dr. Lewis negating Hallier's fungoid theory, and the secondary position to which Pettenkofer's views as to the etiological relations of soil are reduced by Indian experience. Nor does Dr. Ince, who made a special inquiry into the epidemic in the Peshawur Valley, conclude that cholera was there at least chiefly spread by human agency. All, however, are alike agreed that, whether an atmospheric-theory such as that of Dr. Bryden, or the water-theory of Dr. Snow, disclose the *vera causa* of cholera epidemics, "the degree in which inhabitants of a given area are likely to escape will depend greatly on their sanitary condition, on the purity of the water-supply, the excellence of the drainage, and the completeness of all other such arrangements." This volume includes a practical treatise on water-analysis, the joint production of Drs. Macnamara, Parkes, and Angus Smith; some valuable memoranda on conservancy, drainage, and irrigation; and an elaborate and excellent code of rules as to the measures to be adopted on the outbreak of cholera and small-pox amongst British troops.

## HUMAN LOCOMOTION.

IN an interesting lecture by Professor Wilder at the Cornell University on this subject, he notices the curious fact that a person never goes in a perfectly straight line for any distance, but always turns to one side or the other, and at last describes a circle and returns to the point from which he started. The deflection is generally, if not always, from right to left, and is accounted for on the principle that one side of the body tends to outwalk the other. It is a received opinion among American hunters and woodmen, that people who lose themselves in forests or extensive plains thus travel in a circle, turning to the left.

## THE MANCHINEEL POISON.

PROFESSOR KARSTEN has related to the Austrian Pharmaceutical Conference in Vienna his personal experience of the poisonous properties of the famous manchineel tree (*Hippomane manzanilla*) of the West Indies and tropical America, which have been doubted by some naturalists. Being engaged for some hours in collecting its juice, Karsten was attacked with burning sensations of the skin, swelling of the face, eyes, etc., which compelled him to pass three days in total darkness. He attributed these effects to a volatile poison given off by the tree.

## THE PROPERTIES OF THE TUTU PLANT.

IN a paper read before the Wellington Philosophical Society, New South Wales, by Mr. G. H. Hughes of Hokitika, he describes the physiological effects of a small dose of the extract of this plant, *Coriaria Ruscifolia*, which he administered to himself.

"About three-quarters of a pound of the fresh ground shoots were treated with successive quantities of distilled water slightly acidulated. After filtering and adding the acetate of lead in excess, it was submitted to the action of sulphuretted hydrogen, again filtered and evaporated to the consistency of an extract. This extract was well washed with successive quantities of alcohol, filtered, evaporated, and ammonia added, when a precipitate resembling kermes mineral was separated (resinous matter). It was still further concentrated, distilled water added, and again filtered from precipitate; evaporation continued, again treated with alcohol, filtered, and evaporated to a syrupy consistence. On cooling, a few crystals formed with difficulty. This thick solution possessed very active properties; and a quantity of it, certainly not more than one-twelfth of a grain (I was scarcely aware of having tasted it), in five minutes' time produced a most disagreeable irritating sensation in the throat, extending to the stomach, with pain across the region of the stomach, and accompanied by nausea. In a quarter of an hour's time, vomiting came on, which continued more or less for two hours. Very unpleasant sensations continued for two hours more, when, after great flushing of the face, with all but intolerable heat, the effects passed away."

The paper, which is printed in the *Pharmaceutical Journal* of October 7th, 1871, gives an account of the chemical relations of the active principle and of the antidotes to the poison.

## AUSTRALIAN ENTOMOZOA.

AT a late meeting of the Royal Microscopical Society, Dr. Spencer Cobbold handed in a report on some preparations of entozoa, with accompanying notes, forwarded to the Society by Mr. Morris of Sydney, and made observations on some of the most interesting forms. Of the five species collected by Mr. Morris, Dr. Cobbold stated that by far the greatest amount of importance was to be attached to the discovery in Australia of *Stephanurus dentatus*. This entozoon was introduced to the scientific world as early as the year 1834 by Natterer, who found it in large quantities infesting the adipose tissues of a breed of Chinese pigs, on the Rio Negro in Brazil. Up to the year 1870 nothing further was heard of this parasite, when Dr. Cobbold received a communication from Professor Fletcher of New York, stating that it was committing great destruction among the pork-raising districts of the United States, thousands of pigs in some localities falling victims to its ravages. In aspect and structure *Stephanurus* bears a close resemblance to *Trichina*, but is of much larger size, the cysts of the former frequently measuring an inch or an inch and a half in length: its greater magnitude is the principal safeguard against its introduction into the human subject. Dr. Cobbold supplemented his remarks with some observa-

tions on the question of sewage-irrigation connected with the propagation of entozoic diseases. In his opinion it played a very important part; and he did not feel his position in the slightest degree destroyed from the fact of Mr. Hope's ox, brought up for nearly two years on the produce of the "Breton" irrigated farm, being entirely free from internal parasites of any kind. This animal had never been allowed to graze, but had had all its food cut and carried to it; its water was all brought to it, and altogether the animal had been so carefully guarded and nurtured that the entozoa were shut out from any chance of obtaining a foot-hold. The soil, again, on Mr. Hope's estate was of such a porous nature that the matter containing the undeveloped germs was at once absorbed; while on swampy ground, as about Croydon and other low-lying districts, where this mode of irrigation was practised, the roots of the grasses were constantly immersed in it. The prevalence of tape-worm and other entozoic diseases in those parts of India where sewage-irrigation is carried out, is enormous, and thousands of cattle are destroyed as being unfit for human food. This wanton destruction of all carcasses containing traces of *Cysticercus*, or other entozoa, Dr. Cobbold severely censured, as the meat, on being thoroughly cooked, even though infested with parasites, is wholesome, free from any abnormal taste, and its consumption is unattended by deleterious results.

## THE LATE DR. GRIFFITH F. D. EVANS.

AT a special meeting of the Governors of the Shropshire Eye and Ear Infirmary, the following resolution was passed, and a copy ordered to be forwarded to Mrs. Evans.—The meeting specially begs to tender their sympathy with Mrs. Evans on the death of her late talented husband, who, by establishing the Eye Dispensary in 1818, acting as its surgeon for the first fourteen years, and afterwards as its honorary physician up to the time of his decease, has proved himself a real benefactor to the neighbourhood. When it is remembered that the first eye hospital in London was only established in the year 1804, prior to which date diseases of the eye were almost entirely neglected, and that, with the exception of one or two large towns, the Shrewsbury Dispensary was the first formed in the provinces, the giving such a boon to Shropshire and neighbouring counties argues well for the energy, skill, and knowledge of Dr. Evans. The gratitude of a very large number of patients will form a fitting testimonial to a long life of usefulness.

## FEVER-WARDS.

A CORRESPONDENCE has taken place in the public journals as to the necessity of providing accommodation for fever-patients at county hospitals. Where provided in connection with such hospitals, the contagious huts should be in separate parts of the grounds. We have already expressed our views as to the duty of a more ample provision of isolation homes throughout the country.

## THE DISCOVERY OF THE CIRCULATION.

WE learn that it is intended to hold a public meeting shortly to advance the objects of the Harvey Tercentenary. Lord Granville will preside, and the University of London has been asked to lend its large hall. Some interesting relics of Harvey will be collected, including, if possible, busts, early portraits, and—an excellent precedent in matters of circulation—original copies of his books will be shewn.

## METROPOLITAN CHOLERA-HOSPITALS.

MR. STANSFELD'S answer to the deputation of the Metropolitan Asylums Board, on the subject of the Prevention of Cholera, seem to us quite satisfactory. It sets at rest a great many alarms and difficulties which had been started in anticipation of a different plan. His own impression, and that of the medical officers by whom he was guided, was, that in each union, and perhaps in each parish, provision should be made against the spread of cholera. That provision should be made by a central board, like their own, who should be prepared to deal with any cases that might arise. With that view, the Local Government would be willing to discuss with the Asylums Board any measures which might be considered necessary.

DR. DALRYMPLE, M.P.

DR. DONALD DALRYMPLE, M.P. for Bath, has returned from the United States, which he had visited with a view to collect information as to the treatment of habitual drunkards. Dr. Dalrymple, who is in good health, has been absent from England about three months. He visited, while in the United States, Chicago, New York, Boston, Albany, etc., and accumulated much information upon the subject to which he has of late specially directed his attention.

## PUBLIC URINALS IN PARIS.

M. CHEVALLIER, Member of the Council of Public Health in Paris, informs the municipality of that city that one of the first sanitary matters which claims attention is the state of the public urinals. These require improvement as regards their construction, their number, and the means of keeping them in a good sanitary condition. For the latter purpose, he says that coating the wall of the urinal with coal-tar or Norway-tar has proved perfectly successful in two instances in which it has been tried in Paris, in preventing the fermentation and putrefaction of the urine. In concluding his remarks, M. Chevallier urges, as an additional reason for the multiplication of urinals, the dangers which arise from prolonged retention of urine, in the form of various diseases of the urinary organs, such as chronic inflammations, renal and vesical calculi, suppurative cystitis, pyelitis, and similar diseases.

## RELATIONS OF TINEA OF ANIMALS TO TINEA OF MAN.

M. ST. CYR, Professor in the Veterinary School at Lyons, writes on this subject as follows (*Veterinarian*, November 1871). The *tinea* of the cat offers numerous analogies to the *tinea* of children. The disease presents the same essentially parasitic nature; the same cupuliform aspect of the primary lesion; the same composition in the crusts; and, lastly, a perfect resemblance between the constitutive elements of the microphyte that produces the two maladies. There is, therefore, nothing more required to establish a complete identity between them than to prove that they are transmissible from one species to another; that the *tinea* of the child, for example, may be transmitted to the cat; and that the disease which we produce in sowing on the skin of the cat the spores of *tinea* derived from the infant clearly offers all the characters of the affection observed in this animal. On February 7th, 1866, M. Dron, now chief surgeon in the Antiquaille Hospital, sent M. St. Cyr some crusts taken from the head of a child affected with the disease, and under his care. Some days afterwards, he sowed them on the head of a cat, and as a result he obtained a very fine *tinea*. There could be no doubt, then, as to this fact. The *tinea* of the child is contagious for the cat; and this *tinea*, transmitted directly from the child to the cat, offers the same characters as that transmitted directly from cat to cat. We might, therefore, says M. St. Cyr, from this conclude that the *tinea* of the cat may also be transmitted to the child; and that, consequently, there is a complete identity between the two diseases.

## SCOTLAND.

THE number of matriculated medical students in the University of Edinburgh at this date (November 18th) is 599, of whom 209 are registered as first year's students.

## UNIVERSITY OF ST. ANDREW'S.

IN consequence of the election of Mr. Disraeli as Lord Rector of Glasgow University, his supporters at St. Andrew's University, for which he had also been nominated, have determined to bring forward Lord Lytton as their candidate.

## GLASGOW UNIVERSITY.

THE contest between Mr. Ruskin, the Liberal candidate, and Mr. Disraeli, who was brought forward by the Conservatives, has resulted in the election of the latter by a majority in all the nations, representing

a total of 134 votes over his opponent. The election of any particular candidate with prominent political views has practically little or nothing to do with the spirit of the University. At Glasgow, as at other Scotch Universities, the election of a Lord Rector is looked upon chiefly as a pastime by the majority of the students, the influence of the Rector in the government and policy of the University being little understood and as little cared for by them.

## PROSECUTIONS UNDER THE MEDICAL ACT.

IN the case of John A. Forbes, chemist, prosecuting Frederick Adair, 24, Marischal Street, Aberdeen, for a contravention of the 40th section of the Medical Act of 1858, in having advertised himself as an M.D., and having signed his letters Frederick Adair, M.D., he being unregistered, and therefore not a doctor of medicine, nor recognised as such by law, Sheriff Guthrie Smith held this week that there was no evidence that the respondent carried on a business as a medical practitioner. An advertisement had appeared to the effect "Dr. Adair, etc.," but it had not been proved that it was inserted by the authority of the respondent. He, therefore, found the charge not proven, and expenses were allowed to the respondent. Mr. J. A. Forbes also prosecuted John Chadwick, 21, Lodge Walk, for the unauthorised use of the title M.B. The defence was that the letters M.B. and L.V.M. meant medical botanist and licensed vendor of medicine. The Sheriff considered that if a man call himself M.B. he must certainly be understood to hold himself out to the world as possessing the degree of Bachelor of Medicine, and is therefore likely to deceive the public as to his professional abilities. The respondent was fined £10, with £3 3s. expenses. The first decision involves a refusal to the public of the substantial protection to which they are entitled. It shows once more how extremely difficult it is to give effect to the 40th clause of the Medical Act. It would be satisfactory to know whether the Sheriff entertained any real doubt as to the authority on which the advertisement was inserted; and where there would have been any difficulty, had the doubt been foreseen, in obtaining satisfactory evidence to that effect. We are informed that Adair has for years been notoriously practising as one of the advertising medical fraternity in Glasgow. Mr. Forbes seems to be rendering an useful public service in endeavouring to enforce the Act for the protection of the public.

## IRELAND.

THE opening meeting of the Obstetrical Society of Dublin takes place at the College of Physicians on the 18th instant, when the President, Dr. G. H. Kidd, will deliver an address, and the different officers for the coming session will be elected.

THE Council of the Apothecaries' Hall, Dublin, has selected the *British Pharmacopœia* a second time as the subject of the annual prize of five guineas, the examination for which will take place on the first Monday and Tuesday in May, 1872. The prize is to be competed for by apprentices.

## THE MEDICAL EVIDENCE AT KELLY'S TRIAL.

WE have great pleasure in publishing the following important statement:—"The undersigned, having carefully considered the evidence in the recent trial for the murder of police-constable Talbot, and believing that certain statements made during the trial are likely to affect very injuriously the professional reputation of Mr. William Stokes and the surgeons who acted with him, desire to record their opinion that the bullet-wound in the neck of police-constable Talbot was the direct and sole cause of his death, and that no blame can be justly assigned to any of those by whom the wound was treated.—Caesar H. Hawkins, William Fergusson, T. B. Curling, James Paget, Prescott Hewett, J. Ashton Bostock, John Eric Erichsen, John Birkett, George Pollock."

## INTRODUCTORY ADDRESSES IN DUBLIN MEDICAL SCHOOLS.

### MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

THE Introductory Address was delivered on the 6th instant by Dr. ARTHUR WYNNE FOOT. He commenced by alluding to the fact that frequently, of late years, the opening sentences of the introductory addresses in the hospital had consisted of obituary notices, and expressed the general gratification which was felt that on this occasion the prelude was not to be pitched in a minor key. He alluded, in graceful and delicate terms, to the circumstance that he occupied the post of junior physician, vacated by the retirement of Dr. Hudson, now the President of the College of Physicians—rather as his representative than his successor—and regretted that the presence of his predecessor precluded him speaking of him as he could and would. Alluding to the conditions which have led students to regard these annual orations as the capital affliction of human patience, while not expecting that he should escape their criticism in many particulars, he assured them that their ears should not be reassailed with stock quotations from Bacon and the poets. Declining to handle any topics of intense professional interest, or even national importance, such as medical ethics or State Medicine, he preferred to dedicate the occasion to the interests of the youngest student now beginning to prepare himself, by hospital attendance, for the future business of his life. He offered to take him step by step over the course through which he had gone himself. If his food were poisonous, he had tasted every dish, and regarded his position there that day as a convincing proof that his method was, at least, worth their trial of it. He advised them to devote themselves at first to the art or practical part of medicine, which could be learned nowhere but by the bedside of the sick, and nohow but by personal attendance on them and written narratives of their illness. The courtesies of the sick room—no mean accomplishment—were to be upheld here as well as in the chambers of the wealthy. High personal character—a most influential circumstance in deciding their future career—if now acquired, would prove a powerful ægis in a life peculiarly assaulted by temptations of various kinds, and would surround them with an atmosphere pure enough to disinfect even the pestilential breath of calumny. "Work" was the password to success, the key to unlock every difficulty, the thread of Ariadne in the maze of life; but work was not to be of an epileptic kind—in convulsive fits, followed by acute attacks of idleness, which did not exhaust their susceptibilities to fresh ones, but, by repetition, left the mind a desert, with no oasis. Their energy was not to be the flare-up of lighted straw, but a banked-up furnace of dull but sleepless determination. All well-fed, active streams of work found their way, sooner or later, to the great sea of knowledge, and, rising again from that sea, rained down such honour, emolument, and rank, as the profession, the public, or the State, had it in their power to bestow. The scientific part of medicine was to be studied as carefully as the art, but later, because the practice of medicine was the fundamental necessity. Science, as applied to medicine, meant the physical sciences, and not logic, ethics, and metaphysics. Physical science was striding about in the arena of medicine, dealing death-blows to quackeries—doing what the art of medicine could not do; and opposition to the influence of science would be as vain as an attempt to stop the motion of the world, and they would only make a Juggernaut of themselves under the resistless wheels of Progress. Alluding to the necessity of erudition in medicine, as being a profession related to all human knowledge, and to the fact that the writings of many medical men were not properly appreciated in their lifetime, he observed that the brightest epiphanies of intellect were sometimes too strong for the eyes: like comets, they blazed and disappeared before we had time to wonder at them, but they left behind them in their works a glittering train of luminous thoughts, at which men marvelled as they read when the dazzling influence of the meteor was withdrawn. Referring to the threefold object of medicine—the cure, the palliation, and the prevention, of disease—he stated his belief that at no very distant time the prevention of disease would occupy the mind of the public and the profession in a degree anticipated by few at present. He declined to discuss the question on the present occasion how far preventable diseases were the moral police of the Almighty, and as such to be left to work out their own ends; but was not disposed to regard plague, pestilence, and famine, as unavailing torments inflicted by wrathful Omnipotence upon His helpless handiwork. Our present knowledge of the causes of the propagation of cholera was a striking and solemn illustration that the

threat of Rabshakeh enjoyed a wider fulfilment than was ever dreamed of by the Assyrian captain. In the midst of luxury and in the centres of civilisation that disease was spread, even among the high and noble, by an unconscious performance of the act which was held out to the Jews as the dire alternative of their refusal to capitulate to Sennacherib. In some concluding remarks addressed to the senior students, he counselled such of them as had great attainments to preserve their lustre by humility, remembering that the great sea of knowledge was unfathomable, and that the wisest of men could not, during his whole lifetime, do more than wet his ankles on its shore; they must be patient if success seemed slow to come, because the crowns of kings would not fit the brows of infant princes. They should scorn every shape and form of humbug, and abhor and dread it as the tunic of Dejanira. The address closed with a final appeal to those who were commencing to learn clinical medicine at the hospital this winter; that they would enter on the path of education indicated; and that, cherishing a strong faith in the power of work, they would persevere until they found their labours crowned with one of the many diadems of success.

### THE ADELAIDE HOSPITAL.

THE inaugural lecture of the Session 1871-2 was delivered on the 3rd instant by Dr. BARTON, one of the surgeons.

The lecturer said that public hospitals fulfilled a two-fold object—namely, the relief of human suffering, and the technical instruction of students in the wards, which was the very fountain-head of medical knowledge. The primary object of medical skill was, and should ever be, the alleviation of actual bodily affliction, the prolongation of human life, and the prevention of deformity. The secondary purpose of medical study was little lower than its aim—namely, to discover the sources and causes of disease, to suggest the means by which they might be prevented, and to obtain methods by which the various forms of external injury might be rectified. In this light medical practitioners were divided, by an obvious distribution of labour, into physicians and surgeons; one of these classes was concerned with the nature of natural and organic disorders; and the other with external injuries. He referred to further subdivisions of medical science—to the branches concerned with ophthalmic, auricular, obstetric, and other diseases, and remarked that such subdivisions had been already carried as far as was expedient. Excessive splitting up of the highways of medicine into too minute branches might tend to obscure the main features of broad natural laws, and to lead to all bodily disarrangement being referred to the same cause—making the sun, as it were, go round the world instead of keeping the planets in their order. The physician should care for the whole human race, without distinction of race, religion, or complexion; and he trusted that, when it came to the turn of those whom he was addressing to apply their acquirements, they would never allow such distinctions as he alluded to to interfere with their anxiety to assist the afflicted and soothe the weary. When their sympathies were touched by application for relief, they should remember to place pecuniary reward as a purely secondary matter in their consideration. With regard to patients, the medical man was always bound to give the best advice in his power, irrespective of what the position of the sufferer might be. While he paid all due deference to any little prejudices of the patient, the physician should never make any compromise with quackery, nor allow his regard for the opinion of some old woman to permit any nostrum to be tried upon a patient in his charge. If there were danger to the life of a patient, should the medical man tell him so, or encourage him by holding out hopes of recovery which were unlikely to be realised? When death was imminent, it would certainly be false mercy to deceive a patient; but as long as there was no immediate danger, and a hope of recovery, it was better to cheer him forward. There were many instances in which people who laboured under organic disease of the heart lived well for many years. If those persons had been informed of their actual condition their lives would have been rendered miserable, and their deaths would, in all probability, have been hastened. The friends of the patient, however, should be honestly made acquainted with the true state of the case, although there were times when it was even more prudent to express to them a quiet doubt than to give a decisive opinion one way or the other. When they had to deal with cases which had been previously under the care of another medical man, the most generous care should be taken to say nothing to damage his reputation even when they had to differ from him and adopt a different course of treatment. The Army Medical Service now afforded fine openings to young medical men. The dispensary doctors of this country were still, however, for the most part, placed in an unsatisfactory position. The position they occupied had not sufficient official inducement to attract the best men, nor were the

prospects of private practice much more encouraging. The institution of local village hospitals, containing half a dozen beds, with a good, well-trained nurse to attend each, was one of the greatest desiderata in Ireland at present. Very great advantages would be afforded by them. In minor cases, patients would be spared the humiliation of going to the workhouse hospitals; in more complicated ones the delay, inconvenience, and danger of travelling fifteen or twenty miles to the county infirmary; while, at the same time, the local surgeon would have his experience largely improved by having them from the outset under his own supervision. Institutions of the kind were to some extent established in England. They would cost very little, and he trusted that some gentlemen of property in Ireland would soon make a move in that direction.

## ASSOCIATION INTELLIGENCE.

### GLOUCESTERSHIRE BRANCH.

THE fourth annual meeting of the above Branch will be held on Thursday, November 23rd, at 3.30 P.M., in the Gloucester Infirmary.

Members wishing to bring before the Branch any matter of professional interest, will kindly communicate with the Secretary prior to the meeting.

The chief business of the meeting will be the election of officers for 1872.

At 6 P.M. a dinner will be provided at the Spread Eagle Hotel, Gloucester. Price, 4s.

ALFRED FLEISCHMANN, *Honorary Secretary.*

### SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEDICAL MEETINGS.

THE next meeting of the members of the above District will be held at the Fountain Hotel, Canterbury, on Thursday, November 23rd, 1871, at 3 o'clock. The Chair will be taken by the President of the Canterbury Medical Society.

Dinner will be provided at 5 o'clock precisely. Charge, 5s., exclusive of wine.

All members of the South Eastern Branch are entitled to attend, and to introduce friends.

The following papers have been promised:—1. Hernia, with cases of operation for strangulation.—2. Remarks on the diagnosis and surgical treatment of Fibroid Tumours of the Uterus.—3. Variola in Pregnancy and its results.—4. Rupture of the Aorta within the Pericardium.

Gentlemen who wish to be present at the dinner, are particularly requested to inform me on or before Tuesday, the 21st instant.

CHARLES PARSONS, M.D., *Honorary Secretary.*

2, St. James's Street, Dover, Nov. 14th, 1871.

### SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT MEDICAL MEETINGS.

THE November meeting of the members of the above District will be held at the Old Ship Hotel, Brighton, on Friday, November 24th, at 3.30 P.M.; Dr. ALFRED HALL in the Chair.

Dinner will be provided at 5.15 P.M. precisely. Charge (not including wine), 5s.

All members of the South Eastern Branch are entitled to attend, and to introduce professional friends.

Gentlemen who propose to stay to dinner, are requested to inform me the day previously.

Notice of the following papers has been received:—1. A Remarkable Case of Fecundity occurring after the Cure of Endometritis, etc., which had been the cause of Sterility. By A. Hall, M.D.—2. The Danger of Ill-constructed or Neglected Cisterns. By J. Jardine Murray, M.D.

THOMAS TROLLOPE, M.D. Cantab., *Hon. District Secretary.*

35, Marina, St. Leonard's-on-Sea, November 8th, 1871.

### SOUTH-EASTERN BRANCH: WEST KENT DISTRICT MEDICAL MEETINGS.

THE next meeting will be held at the General Hospital at Maidstone, on Tuesday, November 28th, at 4.15 P.M.; Dr. ALBERT DAVIES in the Chair.

Dinner will be provided at the Mitre Hotel at 6 P.M.

*Business to be transacted.*—The election of a member of the Medico-Ethical Committee of the district, *vice* Joy, resigned.

FREDERICK JAMES BROWN, M.D., *Honorary Secretary.*

Rochester, November 13th, 1871.

### CUMBERLAND AND WESTMORLAND BRANCH: AUTUMNAL MEETING.

*The Whalebone-Loop in Midwifery.—Selection of Cases for Asylums.—Pure Air in Sick Rooms.—Misplaced Heart.*

THE autumnal meeting of this branch was held at the King's Arms Hotel, Wigton, on Wednesday, October 25th. The President, Dr. ELLIOT, of Carlisle, occupied the Chair, and opened the meeting with a few introductory remarks on the usefulness of such a society, and the amount of good which might be effected by individual members contributing statistics on certain subjects, which might be collated by the Society. This was independent of the papers and discussions which came before the meetings.

*Communications.*—1. DR. SHANNON (Wigton) read a paper on the Use of the Whalebone Loop in Midwifery Practice. He had first seen the whalebone loop used by Dr. Tiffen of Wigton, about ten years ago, and had used it constantly since that time. The instrument which he employed was a modification of the fillet used by Dr. Westmacott, and was of very simple construction. Only a small amount of damage resulted from the unusual amount of pressure occasionally exerted. In opposition to the views of Ramsbotham, it was pointed out that the instrument acted not only by direct traction but by leverage also. It was the most common substitute for the short forceps, over which it had the advantages of simplicity of construction and ease of application; and it would also very often take the place of the vectis. The cases in which he had employed it most frequently were those in which the progress of the head became delayed at the outlet. He had also used it with success when the head was arrested at the brim, and where others would have had recourse to long forceps. In occipito-posterior and in face presentations the instrument would be found useful.—DR. TIFFEN (Wigton) stated that in the earlier years of his practice he found that delays in labour cases were very common, and he often wished for some means for facilitating the progress of labour. He used to give ergot very frequently, but it acted badly on the child; and on looking out for some simple means he fixed upon the "loop." He now used it in every second or third case, and considered it one of the most universally applicable of instruments.—DR. MILLER (Aspatia) found the loop most useful in pulling down the occiput when fixed behind the symphysis pubis, but for ordinary cases he thought Denham's whalebone forceps more useful.—DR. DICKSON (Whitehaven) often employed Denham's whalebone forceps, but had not tried the "loop." He thought that as much as possible ought to be left to nature.—DR. DODGSON (Cockermouth) thought that instruments ought to be more frequently used; always, in fact, when they could be used with safety.—DR. L'ANSON (Whitehaven) had found a whalebone fillet in a very old collection of obstetrical instruments, many of which were upwards of a hundred years old. He had never used it, and preferred his forceps, which gave him good results.

2.—DR. CLOUSTON (Carlisle) read a paper on the question—What Cases should we send to Lunatic Asylums, and When? [This paper will be published in the JOURNAL].—In the discussion which followed, DR. MACLAREN (Carlisle) referred to the difficulties of home treatment, especially among the working classes.—DR. TIFFEN thought that some cases were rendered permanently incurable by being kept out of asylums, and would like to have information regarding those cases which were most suitable for detention in workhouses.—DR. HENRY BARNES (Carlisle) said that his greatest difficulty in treating cases of insanity at home was, the obtaining of experienced attendants; and that relatives did not usually make good attendants. He referred to the difficulties in the home treatment of cases of acute mania and general paralysis, and thought that the information which Dr. Clouston desired, as to the results of the two kinds of treatment, might easily be obtained through the agency of the Branch.—DR. TIFFEN moved, and DR. DICKSON, seconded, a resolution, to the effect that Dr. Clouston draw up and circulate a series of questions, in order to elicit the information required, and report at a future meeting.

3.—DR. MILLER (Aspatia) read a paper on some Diseases of the Uterus. He related the history and treatment of three series of cases which had recently been under his observation; viz., 1. Cases of simple ulceration of the os uteri; 2. Cases of pedunculated polypus; 3. Procidencia.

4.—DR. ELLIOT (Carlisle) read a paper on the best means for Maintaining the Purity of the Air in Sick Rooms when ventilation is not easily practicable. The ozonising influence of certain essential oils, recently demonstrated by Dr. Angus Smith, was referred to, and the oil of turpentine was mentioned as having given good results in the hands of the author, particularly in cases of abscess of the lung. Cloths saturated with it were hung about in various parts of the room, and were found to keep the air of the room pure.

5.—DR. ELLIOT related the particulars of a case of Misplaced Heart

in a lady. She had recently come to be insured, and he found the apex-beat of the heart on the right side of the sternum, and the liver dulness in left hypochondrium. She was the mother of two children, and had been under observation for several years.—**DR. WICKHAM** (Penrith) had seen a similar case in a new-born child.

*Dinner.*—At four o'clock the members and their friends sat down to dinner. The President of the Branch occupied the chair, and was supported by the Rev. Wm. Schnibben, Vicar of Wigton, Mr. J. M. Hodgson, etc.; and the vice-chair was filled by Dr. Tiffen.

#### BIRMINGHAM AND MIDLAND COUNTIES BRANCH: PATHOLOGICAL AND CLINICAL SECTION.

*Report.*—*Officers.*—*Femoral Aneurism.*—*Eccentric Hypertrophy.*  
*Rupture of Auricle.*

The annual meeting of the Section was held on October 27th; present, **FURNEAUX JORDAN, Esq.**, in the Chair; and thirty-two members. Letters of apology for non-attendance were read from Mr. Alfred Baker, (President) and Mr. J. H. Houghton, of Dudley.

*Report.*—The following Report of the secretaries was read and adopted. The secretaries, in presenting their report, have to congratulate the Section on its continued prosperity. In the amount of work done, in the interest of the discussions, and in the attendance of members, the third session has realised the promise suggested by the early history of the Section. As regards the work, the secretaries feel that the amount of material brought before the members during the year, must have given a beneficial impulse to the study of Pathology in the Midland district, both on account of the excellence of many of the specimens, and the accurate observation entailed on the exhibitors. Although the Birmingham hospitals have afforded, up to the present time, the larger share of the preparations presented to the Section, it is hoped that during the ensuing six months there will be a considerable increase in the proportion of specimens from other sources. The secretaries look with confidence to the officers of the newly opened hospitals of the district, to increase the richness of the meetings by the addition of the results of their new and special opportunities for observation. From the foundation of the Section the attendance at the meetings has been large; and it is gratifying to observe that there has been a steady increase in the numbers present during the past session. The smallest attendance was over thirty. During the year several members have been lost, either from change of residence, or alteration in the list of members of the Branch, or death. Nevertheless, the members now number a hundred and twenty-two, which is an increase of seven on the roll of last year. This increase has accrued, it may be mentioned, without any special effort to obtain new members; the secretaries feeling that there is no special strength in a large number of members who do not attend, for a society which, being prosperous financially, and having only scientific objects in view, seeks importance from the active co-operation of its members rather than from their number. The reports of the meetings have, with one exception, been published in the JOURNAL. The exception was due to the inability of the secretaries to obtain a complete record of the proceedings. To prevent any such exception in the future, and also in order to facilitate the publication of the proceedings of the Section, the secretaries recommend that the following rule be adopted, and issued to the members, viz.—That the reports for publication in the BRITISH MEDICAL JOURNAL be given to the secretaries at the meeting at which the specimens are exhibited; and that the reports be written in a form fit for printing, with the name of the member exhibiting at the commencement.

The *Treasurer's Report*, which showed a balance of £12:7:5 in favour of the Section, was adopted.

*Officers.*—On the motion of Mr. **OLIVER PEMBERTON**, seconded by Mr. **GEORGE YATES**, Mr. J. Hyde Houghton, of Dudley, was elected Chairman for the ensuing year. Mr. **Furneaux Jordan** was re-elected Treasurer; and Dr. Foster and Mr. Vincent Jackson (Wolverhampton) were re-elected Secretaries for the ensuing year.

*Vote of Thanks.*—It was moved by Mr. J. F. WEST, and seconded by Mr. W. C. GARMAN, and carried unanimously, "That the best thanks of this section are hereby given to Mr. Alfred Baker, for the able manner in which he discharged the duties of Chairman of the Pathological and Clinical Section during the past year."

*Communications.*—1. Mr. **OLIVER PEMBERTON** showed a man, aged thirty, a potato salesman, who had consulted him on May 6th, 1871, for a rapidly increasing Femoral Aneurism on the left side, already extending an inch above Poupart's ligament. There was a history of syphilis at eighteen. No known cause could be assigned for the aneurism. The patient was admitted to the General Hospital, and the external iliac artery was tied by ordinary ligature, on May 27th, very high up.

The ligature came away on the twenty-first day. Complete recovery followed, but with a tendency to hernia at the seat of division of the muscles.

2. **DR. A. UNDERHILL** showed a specimen of an eccentrically Hypertrophied Heart. The patient was exceedingly plethoric, weighing twenty stone, and was admitted into the Queen's Hospital, suffering from chronic bronchitis with emphysema. On *post mortem* examination the heart was found to be hypertrophied, with its cavities enlarged, and when emptied it weighed 2lbs. 2½oz. There was no valvular disease, and no atheroma of the aorta.

3. **MR. BENNETT MAY** exhibited the Heart with its Pericardium, of a little boy ten years old, which showed a Rupture of the wall of its Right Auricle, caused by a kick from a horse in the face and chest—there being no external marks of violence. He was seen shortly after the injury, and had the following symptoms. He was unconscious, but apparently in great agony, screaming loudly. He was cold and collapsed, and the pulse beat forty at the wrist, was feeble and intermittent. The pupils were invariably unequal. After vomiting freely, he died just a hour and a half after the infliction of the injury. On *post mortem* examination, the only external mark of violence was a slight bruise on the forehead. There was no fracture of the ribs or sternum, and no bruising or discoloration within the chest. The pericardium was bulging, and distended with blood, of which it contained four or five ounces, in a coagulated condition. The heart was firmly contracted and empty. In the muscular wall of the right auricle was a laceration, about half an inch in length with irregular edges. The structure of the heart was perfectly healthy.

4. **DR. MACKEY** showed a Cirrhotic Liver, from a woman aged 45, not a drinker, but ill-nourished. The symptoms began with general failure of strength twelve months ago; a sallow colour, and "queerness of head" appeared six months ago. Ascites and anasarca followed about three months ago; vomiting was frequent, but she suffered little pain, and died comatose. The organ was small, and its surface was nodulated; the cut surface was rather hard, showing hepatic lobules distinctly. The hepatic cells were atrophied, and showed fat-globules.

#### SOUTH WALES AND MONMOUTHSIRE BRANCH: AUTUMNAL MEETING.

The autumnal meeting of this Branch was held at the Town Hall, Cardiff, on November 7th, at 1.30 P.M.—the President, **GEORGE PADLEY, Esq.**, in the Chair. Nearly forty members and visitors were present.

After the minutes of the annual meeting had been read and confirmed, thirteen new members were elected to the Branch, fourteen new members having been previously elected to the General Association by the Council.

*Communications.*—1. **W. Taylor, M.D. (Cardiff).** Excision of the Knee-joint. The paper was illustrated by two patients who had undergone the operation, and by photographs.

2. **A. Sheen, M.D. (Cardiff).** Sayre's Splint shown applied on a patient suffering from Hip-joint Disease. Attention was drawn to the relative cost of getting the splint made in London (£2:10) or the country (about 15s.)

3. **J. H. Wathen, Esq. (Fishguard).** Case of Lithotripsy. Mr. Wathen also showed a stone, of the size of a walnut, removed from a female patient *per urethram*.

4. **A. Sheen, M.D. (Cardiff).** Case of Popliteal Aneurism cured by Pressure, with subsequent Amputation of the opposite Limb for Popliteal Aneurism on that side.—Case of severe Compound Comminuted Fracture of Tibia and Fibula: recovery with an useful limb.—Both patients were shown five years after having been under treatment. They were both under Dr. Taylor's care in the Cardiff Infirmary in 1866.

5. **J. Milward, Esq. (Cardiff).** On Placenta Previa.

6. **C. T. Vachell, M.B. (Cardiff Infirmary).** Exhibition of Microscopic Pathological Specimens, and of some Microscopic Specimens kindly lent by Dr. George Johnson (London), showing the Circulation in the Kidney.

7. **J. G. Hall, Esq. (Swansea).** A case of Embolism, and one of Carotid Aneurism.

*Dinner.*—At 4.30 P.M., twenty-nine gentlemen and six guests sat down to an excellent dinner; the President in the Chair, supported on his right by Mr. T. J. Dyke, President-elect, the Vice-chair being occupied by Dr. Sheen, one of the honorary secretaries. After the dinner, some discussion, introduced by Mr. James Lewis of Maesteg, took place on the desirability of establishing a Convalescent Hospital somewhere on the sea-coast in the county of Glamorgan.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH :  
GENERAL MEETING.

The second general meeting of this Branch was held at the Midland Institute, Birmingham, on November 9th—OLIVER PEMBERTON, Esq., President, in the Chair. There were also present fifty-three members and visitors.

*New Members*—Eight new members of the Branch were elected.

*Communications.*—1. Mr. ARTHUR BRACEY exhibited the patient whom he had shown at the last meeting of the Branch, and in whose eye the Lens had been disorganised and Dislocated. The operation for removal was performed by making a corneal incision with a Von Gräfe's knife and withdrawing the lens by the scoop. A good result was obtained.

2. Dr. ALFRED HILL read a paper on Old and New Methods of Water Analysis. He began by referring to the care which the ancient Jews, Romans, and Greeks, took in order to obtain supplies of pure water. The writing of Hippocrates showed the importance which the Greeks attached to the purity of water for drinking purposes. He then gave a description of the various methods of analysis of water, and showed how in late times attention had been principally given to the estimation of organic matter and to a discovery of its chemical nature. The different processes were reviewed *seriatim*. The simple incineration process and its modifications were stated to be defective. The permanganate process gave different indications with the same quantities of different kinds of organic matter, and therefore was not trustworthy. The processes of Messrs. Wanklyn and Chapman, and that of Dr. Frankland and Mr. Armstrong, were examined; and Dr. Hill stated that, after having used the last named process upwards of three years, he was more than ever impressed with its superiority and utility.

3. Dr. B. W. FOSTER read a paper on the Lactic Acid Treatment of Diabetes.

## REPORTS OF SOCIETIES.

## CLINICAL SOCIETY OF LONDON.

FRIDAY, NOVEMBER 10TH, 1871.

WILLIAM W. GULL, M.D., LL.D., President, in the Chair.

*Wound of Intestine in Ovariectomy.*—Mr. CHRISTOPHER HEATH read a paper on a case of wound of the intestine made during ovariectomy, with recovery. The patient was under his care in the Hospital for Women in November 1870, suffering from an ovarian tumour, which had been repeatedly tapped, and for the removal of which an attempted ovariectomy had been undertaken by another surgeon a year before. The patient was worn out with pain and sickness, and was anxious that another attempt at ovariectomy should be made. This was undertaken by Mr. Heath on November 25th, 1870, when very extensive adhesions to the surrounding structures were found. On enlarging the abdominal incision with scissors in the ordinary way, an empty coil of small intestine, which was closely adherent to the wall, was divided in three-quarters of its circumference. The removal of the cyst was accomplished with considerable difficulty, the pedicle being tied and dropped. Mr. Heath then attached the bowel to the skin with silk sutures, forming an artificial anus, and closed the abdominal incision with wire sutures. The patient made a perfectly good recovery, faeces and flatus passing by the artificial opening on the second day, and solid motions *per anum*. The silk sutures were removed on the eleventh day, and the patient was moving about at the end of a month. Three applications of the actual cautery were made to the edges of the fistula to contract it, but it did not close, and the patient left the hospital in April 1871. She was presented to the Society in a very comfortable and healthy condition, the use of a belt and air-pad satisfactorily retaining all fecal matter, and the patient having regular stools.—Mr. MAUNDER thought the moral of the operation to be, that in such circumstances we should be cautious not to use scissors.—Dr. EDIS had been present at the operation, and alluded to the difficulties of the case. He believed that the accident was unavoidable, and that Mr. Heath deserved all credit for having shown himself equal to the occasion by taking care of the gut, and sewing the cut edges to the abdominal wall, instead of leaving the injury alone in the belief that there was no hope for the patient.—Mr. JOHN SCOTT also referred to the unusual difficulties of the operation, at which he was present. Had a director been used, the result would have been the same as had occurred in the use of the scissors. The gut could not be separated from the peritoneum.—Mr. DE MORGAN, in expressing surprise at the favourable termina-

tion of Mr. Heath's case, referred to the extraordinary differences observed in the recovery of patients from ovariectomy. Cases in which great interference with the abdominal viscera has been found necessary, the tumour being perhaps torn away, recovered; while others presenting the most favourable conditions for recovery proved fatal. He then related several illustrative cases, and expressed his opinion that Mr. Heath showed great aptitude and skill in treating the case as he did.—Mr. LAWSON remarked that serous membranes which had been long inflamed, might be interfered with to a very great extent, as, for instance, the tunica vaginalis, which might be dissected out without producing alarming symptoms.—The PRESIDENT, after complimenting Mr. Heath on his honesty in bringing forward the case, expressed his desire to know in what position of the small intestine the opening was, and what Mr. Heath had to say about the propriety of using the scissors.—Mr. HEATH, in reply, said that he was in the habit of using the fingers first, but was not prepared for the existing state of things. He disagreed with Mr. Maunder, however, about the use of the scissors in the case. He could not give any definite answer regarding the position of the wound in the intestine. The contents hardly possessed a fecal odour.

*Thoracentesis in Pleuritic Effusion.*—Dr. JOHN MURRAY read a paper on thoracentesis in a case of simple pleuritic effusion. The patient, a healthy-looking and muscular man, aged 38, was the subject of very extensive serous effusion into the left pleura, the heart being pushed entirely over to the right side of the chest, and the left lung completely compressed. His respiration was generally about thirty per minute, his pulse 120, and the temperature 101. Although the acute symptoms had subsided a month after the commencement of the attack, and a fortnight after the pleura had become completely filled, still there were no evidences of diminution of the fluid, notwithstanding that many of the usual remedies had been tried. The ultimate and complete recovery of the left lung was being endangered, and the healthy one and the heart and large vessels interfered with, while the man's general health was suffering. Dr. Murray decided to employ thoracentesis. Accordingly, Mr. Hulke performed the operation, and drew off thirty-five ounces of clear serous fluid by means of Nyrup's modification of Bowditch's aspirator, the trocar being passed into the chest between the fifth and sixth ribs, where the digitations of the serratus magnus meet those of the obliquus externus muscles. The effect of the operation was to diminish in six hours the respirations, pulse, and temperature in a remarkable manner. Ten days after the operation, all evidences of fluid were gone, and vesicular breathing had returned to a considerable extent over the upper two-thirds of the lung. The man was discharged five weeks after the operation with evidences of a good recovery. The breathing and percussion-resonance were still deficient over the left side, and friction-sound was everywhere heard; but he suffered no inconvenience from the last symptom, and appeared in excellent general health. Dr. Murray thought that paracentesis thoracis was the proper treatment in this patient's case; and expressed his opinion, after quoting the experience of Dr. Bowditch of Boston and others, that in all cases of extensive and uncomplicated serous effusions, the operation should be performed at least immediately after the subsidence of the acute symptoms.—Dr. MOXON related a case in which the patient rapidly recovered during treatment by the dry method, by diminishing the amount of fluid in the diet; and asked Dr. Murray if this plan had been adopted in his case.—Dr. ANSTIE referred to the dry method of treatment as painful and doubtfully effective. He asked why we should continue to give in such cases as that brought forward, iodide of potassium, diuretics, and the like, when we had the means of withdrawing the fluid at once in a safe manner. If properly performed by Bowditch's aspirator, air need not enter the pleura; and the operation produced little or no pain. The trocar furnished, also, the means of completing the diagnosis without harm.—Dr. PLAYFAIR testified from considerable experience to the good results obtained by the operation. When the fluid was serous, as much should be removed as would allow the remainder to become absorbed; but the aspirator was costly, and the fluid might be readily withdrawn by a tube under water. In empyema, when it was desirable to effect a continuous drainage, to reduce absorption to a minimum, he was in the habit of employing, at the Evelina Hospital for Sick Children, with much benefit and comfort to the patients, a plan whereby this constant drain was kept up by passing into the chest a drainage-tube, which was conducted below the bed and kept under water. By this means he had found a rapid diminution of pus in a very short space of time.—Dr. THOROWGOOD thought that the operation was now much more successful; but this was due, not to the complicated instruments in use, but to a more careful selection of cases. In empyema, he thought it a matter of little importance whether air were admitted into the pleura or not.—Dr. WILKS asked what advantage the instrument employed in the present case possessed, and whether it assisted the lung to expand.—Dr.

DOUGLAS POWELL remarked that the principle of the instrument was, that by means of a fine trocar a large quantity of fluid which might not otherwise come out was withdrawn by suction. He thought the object should be to withdraw a certain amount of fluid, and to allow the rest to be absorbed. He believed it to be important in empyema to withdraw the fluid without admitting air.—Mr. DE MORGAN referred to his having, he believed, been the first surgeon to put a drainage-tube through the chest in empyema. He doubted whether Dr. Playfair's plan would be of much advantage in purifying the pus in those cases in which it became putrid.—Dr. EDIS alluded to the stress which Dr. Bowditch laid on the early performance of the operation, the value of which had been borne out in his own experience.—Dr. ALTHAUS said that the application of electricity was known to cause the absorption of fluid from some serous sacs, as in hydrocele, and referred to a case of ovarian dropsy abroad in which a similar result had ensued, and suggested this mode of treatment in pleuritic serous effusions.—Dr. BARCLAY had always found simple pleuritic effusion very amenable to treatment, and would like to know what were the advantages of the operation.—Dr. DUFFIN spoke in favour of thoracentesis, and pointed out that, by allowing the functions of the organs to be interfered with and the organs dislocated, absorption of the fluid became thereby diminished.—Dr. JOHN OGLE referred to the experience at St. George's Hospital, which was favourable to the operation, and alluded to a case in which the patient had died during its performance.—Dr. DUCKWORTH, in advocating the great advantages of thoracentesis, observed that, if the chest refilled, it might with safety be tapped again and again.—Dr. LANGDON DOWN related his experience of this method of treatment, which was favourable. He had had recourse to the operation in five cases—in one to relieve dyspnoea, and in the others to save time.—The PRESIDENT pointed out that several things were being discussed by the members. The case in point was one of simple catarrh of the pleura, and the question was, whether such cases should be left to dry up or not: the issue was hastening the recovery. He alluded to the remarks which had been made on the supposed value of diuretics in pleuritic effusion, and said that he had thought all such opinions had been now given up. His own practice in simple pleuritic effusions had always been to make the patient hungry and keep him so.—Dr. MURRAY, in reply, said that the question discussed in his paper was limited to thoracentesis in simple and extensive pleuritic effusion—a plan of treating such cases which he strongly advocated immediately the acute stage had passed off. By this means the chest was at once relieved, and practically without danger, if done carefully with the aspirator. The sufferings of the patient were in every way diminished; the danger to the compressed lung was reduced as far as possible; and much time was saved in getting rid of the fluid, as compared with the old plan of treatment by diuretics and the like. Moreover, the operation might be repeated again and again, if necessary. Why then not withdraw the fluid by this means? He had found no difficulty on one occasion in drawing off under water fluid from the pleura by means of a common trocar and piece of tubing. The advantages of the aspirator over such a plan lay chiefly in this, that a fine trocar could be employed, and more fluid could frequently be withdrawn, aided as its flow was by suction. The instrument, he thought, had no influence in expanding the lung.

[Dr. Bouchut is discussing this subject, in a somewhat elaborate paper in the current numbers of the *Gazette des Hôpitaux*, in which he gives an interesting *résumé* of the medical history of the proceeding. The following bibliography of recent French writers on the subject may be useful to many physicians who are just now giving attention to this subject.—J. Guérin, *Gazette Médicale*, 1854, De la Thoracentèse par la Méthode Sous-cutanée.—Trousseau, Thoracentèse dans une Pleurésie chronique, *Bulletin de la Société des Hôpitaux*, 1850, p. 72.—Gendrin, Thoracentèse, 30 ou 40 fois, de 1830 à 1840, avec Trocart et Bistouri, *ib.*, 1850, p. 74.—Blondel, Ouvrage sur la Thoracentèse, 1815 et après.—Puloux, *Bulletin de la Société des Hôpitaux*, 1850, p. 98, Indications de la Thoracentèse dans la Pleurésie latente.—Gubler, Thoracentèse dans la Pleurésie purulente, avec Trocart, *ib.*, p. 119.—Marotte, Thoracentèse dans l'Hydrothorax, *ib.*, p. 133; Thoracentèse dans la Pleurésie purulente. Guérison, *ib.*, p. 296.—Aran, Thoracentèse et Injections iodées, *ib.*, p. 371.—Barth, Thoracentèse dans l'Hydrothorax, *ib.*, p. 387.—Marotte, Rapport sur la Thoracentèse, *Mém. Soc. des Hôpitaux*, 1853, p. 165.—Barthès, Pleurésie purulente: ponction: application d'une canule et injections d'iode, *ib.*, 1855, p. 354.—Léguen, Pleurésie purulente, 24 ponctions, et, à la fin, application d'une canule pendant 4 mois: injections; guérison. *Mém. Soc. des Hôpitaux*, 1854, p. 366.—Héard, Thoracentèse dans la Pleurésie hémorrhagique; Mort, *ib.*, 1861, p. 16.—Bernard, Thoracentèse dans la Pleurésie aiguë simple; Mort, *ib.*, 1856.—Maurice, Thoracentèse dans la Pleurésie purulente: 3 ponctions suivies de fis-

tule: application d'une canule: injection iodée; guérison, *Mém. Soc. des Hôpitaux*, 1856.—Archambault, Thoracentèse dans la Pleurésie simple, *ib.*, 1864, p. 5.—Roger, Thoracentèse dans la Pleurésie purulente: 5 ponctions, puis application d'une canule; guérison, *ib.*, 1864.—Blachez, Thoracentèse par Trocart capillaire, *ib.*, 1868, p. 15.—Dupré de Montpelier, Sur la Thoracentèse dans les épanchements simples, *Bulletin de l'Académie de Médecine*, 1869.—Boinet, Des Injections dans la Pleurésie purulente, *Archives de Médecine*, 1853, et *Gazette Médicale*, 1855, p. 813.—Dieulafoy, De l'Aspiration pneumatique, Paris, 1870.—ED. B. M. J.]

ERRATUM.—*Zinc Paste*. In the report of the Clinical Society in the JOURNAL of November 11, p. 567, column 2, line 14, read "Mr. Hulke, in answer to the President, said that zinc paste was prepared by mixing the chloride of zinc with starch and a little tincture of opium to the consistence of honey."

## PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, NOVEMBER 7TH, 1871.

JOHN HILTON, F.R.S., President, in the Chair.

*Dilatation of the Kidney*.—Dr. PYE-SMITH exhibited a specimen of dilatation of the kidney, taken from the body of a young man aged 24. He had received a kick from a horse on the left side four years before the symptoms for which he was admitted into Guy's Hospital had appeared. These commenced with diarrhoea; and on the second day he noticed an abdominal tumour on the left side, which was thought, on admission, to be connected with the kidney. It was punctured as a means of diagnosis, and several pints of blood and pus passed out. The tumour filled again, and was a second time tapped. The patient shortly afterwards died. At the necropsy, adhesion of the left lung to the diaphragm was found, and peritoneal adhesions over the whole left side of the abdomen. There were a large dilated kidney and ureter. The urethra and bladder were healthy. The other kidney was hypertrophied, and apparently affected with parenchymatous inflammation. The ureter was strictured about two inches from the pelvis of the kidney, where he believed it had been ruptured, and afterwards contracted.—Dr. SEPTIMUS GIBSON asked what had ultimately carried off the patient.—Dr. DICKINSON said the blow must have been very great to rupture the ureter, so deeply situated as it is. Perhaps the whole mischief originated from a calculus. He had had a similar case to that before the Society, from calculus.—Dr. HARE considered it not necessary that there should be a calculus to produce these effects. A hydronephrosis was sufficient. He considered the specimen one simply of dilatation from pyelitis.—Dr. THOROWGOOD related a similar case, in which a calculus was the origin of the mischief.—Dr. MURCHISON referred to a case due to injury of the ureter.—Mr. HULKE pointed out that viscera were often ruptured without any external appearance of violence.—Dr. PYE-SMITH, in responding, observed that careful examination was made for a calculus and crystals, but none of any kind were found. The boy died as the result of suppuration and profuse diarrhoea.

*Tuberculous Lung checked by Quinine*.—Mr. SQUIRE brought forward the case of a boy who two or three years ago exhibited signs of tuberculosis, which were checked by quinine. In autumn, oedema of the legs and albuminuria, with hyaline and granular casts, appeared; and he died shortly afterwards. The apex of the lung, where symptoms had previously appeared, was found to be full of grey tubercle. There was no cavity, and no pneumonia. The intestine was in a state of ulceration.—Mr. HULKE, in alluding to a remark made in the discussion, said that the removal of a diseased limb in phthisical patients often relieves the lung-affection—a fact which should be set up against the idea that, by curing one part, the disease breaks out in another.—Dr. DOUGLAS POWELL pointed out how important it was, in connexion with the alleged effects of quinine, to know whether the tubercular disease present in this case was old or recent.—At the request of Mr. SQUIRE, the specimen was referred to Dr. Powell for report.

*Diseased Heart and Embolus of the Spleen*.—Dr. KING exhibited an enlarged embolic spleen and diseased heart, taken from the body of a man who died in the Middlesex Hospital. The patient had been the subject of acute rheumatism six years ago. On admission on August 29th, there were symptoms pointing to mischief in the spleen, and on October 29th the cerebral apoplexy from which he died in a few days. The mitral valve was found in advanced disease, an orifice in the vegetations leading into a cavity. There was pericarditis. In the spleen, which was very much enlarged, was an unusually extensive embolism; and in the anterior portion of the right cerebral lobe was a similar mass. Dr. King, in answer to Dr. Murchison, said that the mass in the brain was of a cheesy consistence, and found microscopical

pically to be composed of oil and granular matter. There was no plug discovered in the cerebral arteries.—Dr. MURCHISON had asked the question because in many cases without any cardiac disease, as in fevers, so-called embolisms are found. He related a case without cardiac disease, in which the internal organs and the brain were affected by embolism, and gangrene of the legs took place. These were all probably due to the fever-poison; so also in acute rheumatism.—Dr. CAYLEY alluded to cases of pulmonary apoplexy in which fibrine in the heart shortly before death has produced these. He thought Dr. Murchison's cases were thus produced.—Dr. MURCHISON rejoined, that this explanation would not answer in his case, as the embolism occurred several weeks before death, and there was no atheroma present.—Dr. PYE-SMITH considered the cases in question to be of the nature of thrombosis.

*Epithelioma.*—Mr. HULKE related four very instructive cases of epithelioma, which illustrated the local character of the disease. They all presented the microscopical characteristics of epithelioma, and in none was there a family history of cancer.—Dr. EDIS gave his experience of epithelioma in uterine practice, and referred to several cases in which, by early and complete destruction of the diseased structures by means of the actual cautery, the disease had been completely arrested for the time at least. There had been no constitutional symptoms in these cases.

#### MEDICAL SOCIETY OF LONDON.

MONDAY, OCTOBER 30TH, 1871.

ANDREW CLARK, M.D., F.R.C.P., President, in the Chair.

MR. TEEVAN exhibited.—1. A new kind of Lithotrite, the handle being square and heavy, and the ordinary button being replaced by a vertical slide. The heavy handle enabled the lithotrite to glide into the bladder more easily, whilst its squareness permitted firmness when grasped—to be united with the greatest delicacy of manipulation. The act of pressing on a vertical slide was more simple than pushing a button to and fro. 2. A Syringe, for injecting the deep urethra, made of glass, capable of holding a few drops of fluid and having an elastic nozzle, five inches long, surmounted by a ball. A stiff nozzle was very undesirable. The ball permitted accuracy in application, for measurement could not always be relied on, as the penile urethra was continually altering in length. 3. A Syringe for patients to use either for gleet or gonorrhœa. It consisted of a small elastic ball attached to a nozzle of bone three and a half inches long. It was durable and inexpensive. Mr. Teevan also exhibited the *Bougie olivaire à ventre*, the *Bougie à trois boules* and M. Mercier's *Sondes coudées et bicoudées*.

#### MANCHESTER MEDICAL SOCIETY.

WEDNESDAY, NOVEMBER 1ST, 1871.

JOHN THORBURN, M.D., President, in the Chair.

*Cancer of the Stomach.*—Dr. SIMPSON showed a section of a stomach obtained from the body of a lady. The walls of the stomach were nearly equally infiltrated with cancerous deposit, which ended abruptly at the pylorus in a raised, rounded edge. The fundus was quite free from scirrhus, and formed a flaccid pouch-like appendage to the mass of the remaining portion of the organ. The stomach was greatly contracted, so as to barely admit the thumb; the cardiac orifice seemed healthy. The glands in the vicinity of the stomach were diseased, but no secondary deposits were found in the liver or kidneys. The chest was not examined.

*Spontaneous Deposit of Cholesteroline Crystals.*—Dr. W. ROBERTS exhibited a specimen of urine passed by a man aged 30, who had suffered from frequently recurring attacks of hæmaturia. There was no tumour in either lumbar region, but pain was complained of over the left kidney. The general symptoms pointed to renal calculus. The presence of a hydatid tumour was suspected, but, although carefully looked for, no hooklets of the echinococcus could be detected. In addition to blood-corpuses, the urine contained an abundant natural deposit of cholesteroline crystals, with granular or "inflammatory" corpuses. Dr. Roberts remarked that the only other case on record in which cholesteroline occurred as a spontaneous urinary deposit, was to be found in the *Transactions of the Pathological Society of London*.

*Fibrinous Casts of the Ureter.*—Dr. W. ROBERTS showed some long worm-like casts which had been passed in the urine of the same patient. There were no tube-casts present.

*Cystic Degeneration of the Kidneys.*—Dr. W. ROBERTS exhibited the kidneys of a lady aged 52, the mother of a large family, the youngest of whom was four years old. She had been in her usual health, although

somewhat waxy in appearance, till October 24th, 1871, when she was seized with bilious vomiting, which proved excessively obstinate, lasting till the 27th. Epileptoid convulsions came on during the forenoon of the 28th; and in the evening, when Dr. Roberts saw her for the first time, she was semiconscious, but answered questions. Six ounces of urine were withdrawn by the catheter; a moderate amount of albumen was present. Tumours extending to the iliac crest were detected in the loins. The fits recurred frequently during the night of the 28th, and also on the 29th; there was now observed extreme contraction of the pupil, and the tongue was dry. Sixteen ounces of urine drawn by the catheter contained about one-twelfth of albumen; it was pale, and of specific gravity 1.013; it contained no tube-casts, but gave a speedy deposit of crystals of triple phosphate and of urate of ammonia. The patient died on the 30th; and at the necropsy, the kidneys were found transformed into a congeries of cells, varying in size from a pea to an egg; no trace of renal structure remained. Dr. Roberts remarked that this was a somewhat rare condition in adults, and that these cysts were formed by the expansion of portions of uriniferous tubes, and occlusion and consequent atrophy of the intermediate portions; he considered that there was some affinity between this form of degeneration and the granular atrophic forms of Bright's disease.

*Ligateur Automatique.*—Mr. STOCKS showed an instrument bearing this name. It was designed for the purpose of applying ligatures to arteries, especially at the bottom of cavities.

*Self-holding Artery Forceps.*—Mr. LUND showed a pair which he had designed on the principle of the "bull-dog" forceps. The mouth of the forceps formed half a sphere, inside of which was a little lip or groove which received the end of the artery; and Mr. Lund had found that it saved assistants, that its weight dragged down the vessel which was thus kept out of the way, and that it took up only the point of the vessel.

*Cancer of the Kidney.*—Dr. LLOYD ROBERTS showed a specimen obtained from the body of a male child aged nine months. There had been a distinct abdominal tumour almost from birth, which had been gradually increasing up to the time of its death. There had never been hæmaturia or any urinary symptoms. The tumour weighed five pounds and a half, and presented the distinct histological characters of malignant disease.

*Intestinal Concretion.*—Mr. LUND exhibited a specimen obtained from the stomach of a pony. It weighed 1½ lbs., was almost spherical, and had a number of square and hexagonal projections on its surface.

*Abortion.*—Dr. HADDON narrated two cases, and showed the specimens. In the first case, pregnancy had gone on till nearly the end of the second month; and, in the preparation, the chorion was well shown, with the embryo of the size of a barley-corn; in the second, the specimen was detached two months and a half after the cessation of the menses.

*Extraordinary Case of Fœtation.*—The Committee appointed at last meeting to examine the specimen shown by Dr. FLETCHER, reported that the preparation consisted of a cyst enclosing a full-grown fœtus attached to the placenta, both fœtus and placenta being almost universally adherent to the cyst-wall. The fœtus was covered with an encrustation of a gritty nature, not unlike lime; the cyst-wall was in a state of fatty degeneration. As there was no trace of the uterus or its appendages in connection with the cyst, it was impossible to arrive at any conclusion as to its original location within the abdomen.

## SPECIAL CORRESPONDENCE.

### EDINBURGH.

[FROM AN OCCASIONAL CORRESPONDENT.]

THE Winter Session here is now fairly commenced, and the classes are in full swing. The opening meeting of the Royal Medical Society was held on Friday, when an able address was delivered by Dr. Andrew Wood. The hall was crowded. The truth involved in Dr. Wood's advice that students should consider an active interest in the proceedings of the Society an essential part of the medical curriculum, has been fully borne out in the career of many of its members.

As usual on such occasions, there was considerable excitement amongst the students during last week in connection with the rectorial election; and, as might have been expected, the lady-doctor movement exercised some influence on the voting. It appears that Sir Roundell Palmer, the liberal candidate, had expressed an opinion, by telegram, against "mixed medical education", in reply to a question put to him on the subject. A deputation of medical students had, with a similar object, waited upon

Sir William Stirling-Maxwell at the railway station, to ascertain his views regarding "the subject of the admission of women into the medical lectures of the University", but without satisfaction. Sir William's answer, as given in an explanatory letter written afterwards, was characteristic of the man. "I told them", he said, "that it was a subject upon which I had not arrived at any definite opinion; and that even if I had done so, I must decline to answer any questions put with a view of influencing the election. Our interview was so brief, that I had not the opportunity of explaining so fully as I might have wished to have done the reasons of my refusal. I hope, however, that they, upon reflection, and that you will agree with me, that if one question may be asked, any other may be proposed, and that the character of your rectorial elections, and of the honour conferred upon the person elected, would be essentially changed by the introduction of the practice. I must, with all respect to my supporters, decline all share of responsibility in such a change, and, on the terms proposed, would neither desire nor accept success." The effect of the letter was, I think, to increase his chances of success in the election, had there been any doubt as to the ultimate result of the contest from the commencement. The high academical culture and attainments of both candidates would have rendered the contest a very close one, had it not been that Sir William's intimate knowledge of the Scotch Universities, and the distinguished position which he, as a Scotchman, had attained in the eyes of his countrymen, gave him superior claims to the honour. His majority of 594 against 502 may be supposed to be explained by these reasons. I say supposed, because it is impossible to say how an election may go when the constituency is very largely made up of young men and boys who have no idea what the duties and authority of the Rector are, and who look upon the contest as a legitimate opportunity for pelting each other with flour-bags and peas. I think I may safely say that a considerable number of the voters had never previously heard of Sir R. Palmer or his successful opponent, and know little more of them now. I am sure it would be for the advantage of the University, were the election vested in the hands of a constituency capable of deciding on the merits of the candidates and the wants of the University.

The *Senatus Academicus* met on Saturday to consider the existing regulations about female medical students, when it was decided, by a majority of fourteen against thirteen, to recommend to the University Court that they should be rescinded, without, however, interfering with those ladies who have already matriculated. The minority in the *Senatus*, it is said, intend to appeal to the University Court. As a consequence of the decision of the *Senatus* of the University, the friends of the female medical movement are showing unusual activity. At a meeting held on Monday by the General Committee for Securing a Complete Medical Education for Women in Edinburgh, the Lord-Provost—a warm supporter of the ladies—in the chair, the following resolution was passed, showing that the ladies and their friends believe themselves to be obtaining increasing support with the public, and that they intend to continue fighting *à outrance*:—"That it be remitted to the Executive Committee to watch over the two questions that have been brought before the meeting, viz.: (1) The means by which those ladies who have already begun their medical studies under the Regulations of the University of Edinburgh may be enabled to complete them; and (2) what steps should be taken by the General Committee, in view of the action of the University authorities, in regard to the resolution of the *Senatus Academicus* of date 11th November last, and to report thereon to a subsequent meeting of the General Committee."

The Obstetrical Society was opened last week on Wednesday, with an address by Dr. Keiller, the President, on the "Progress of Obstetrics." A *conversazione* was held afterwards, when a number of preparations, instruments, and other objects of interest were exhibited. The attendance was large and influential, and the meeting passed off most successfully.

As in most of the English schools, the entrance of medical students at the University is larger than last year. Up to Saturday last the total number of medical students who had matriculated was 558, as compared with 496 on the corresponding day of the session last year. Thus the forebodings of certain persons that the Edinburgh School of Medicine is on the decline, is not founded on fact, if the number of entries be a proper criterion. We may not have so many names of world-wide renown as when Goodsir, Simpson, and Syme were alive, but our teaching power is, nevertheless, equally strong and efficient as before.

Sir Robert Christison's honours are, of course, looked upon by every one as thoroughly well merited, and Mr. Gladstone's behaviour in the matter has given general satisfaction. Sir Robert has devoted the best part of his life heart and soul to the interests of the University, and has shed lustre on the chairs he has filled. He is one of the representative men of science, and the leading medical man in Scotland, and possesses a

personal influence which is very remarkable, not only amongst his old pupils, who are numbered by thousands, but with the bulk of the leading citizens of Edinburgh. I remember that some time since a paragraph appeared in the *BRITISH MEDICAL JOURNAL*, stating that Government intended conferring titles of honour on several medical men, in which the claims of Dr. Christison, Dr. Stokes, and Mr. Paget, were strongly urged by you. It is gratifying to observe that two of these gentlemen have already received the honour of baronetcy, and I am sure that the whole profession will support your recommendation of the third name.

## CORRESPONDENCE.

### LIP-READING BY THE DEAF AND DUMB.

SIR,—In a letter signed "Truth", which appears in the last number of the *BRITISH MEDICAL JOURNAL*, it is stated, on the authority of Dr. Gallaudet of Washington, that only a comparatively small percentage of deaf-mutes "can be taught to converse on commonplace subjects with their teachers, family, and intimate friends." Permit me to say that, as Chairman of the Committee of the Deaf and Dumb Home in Burton Crescent from its establishment up to a very recent period, it has been my privilege to see all the children admitted into that institution, and in no one single instance has material difficulty been found in imparting the new method of instruction. Of course, if idiocy be associated with deaf-mutism, all efforts to teach a child to speak would be unavailing; and I need hardly add that the ease and rapidity with which the little ones learn vary according to their natural aptitude.

An ounce of practice is worth any quantity of theory; and I recommend all my professional brethren who take an interest in the subject to visit either the Home in Burton Crescent or the School in Euston Road. Both institutions are under the direction of Mr. Van Praagh, who will be happy to give every facility to medical men desirous of judging for themselves of the merits of the system.

I am, etc., HENRY BEHREND, M.R.C.P.E.

Norfolk Crescent, W., November 13th, 1871.

SIR,—In your last week's issue your correspondent, signing himself "Truth", makes such statements on the education of the deaf as require direct contradiction from me.

The instruction of the deaf and dumb, on the so-called German system, has never been publicly introduced in any National School in England, hence his mistake as regards the schools in England and Scotland, where hitherto either absolutely the French or the mixed system are in vogue. I can, from experience, say with confidence that the course of instruction need not last longer than seven or eight years. As to the voice of the deaf—of course the inarticulate voice is harsh, but the teachers can change this so as to make it not only quite bearable, but not actually disagreeable to hearers; and, if they cannot, they ought to confess their ignorance, and not the impossibility of the practice.

I am most happy to be able to inform you that schools are being now established in America, where the system of articulation and lip-reading will be applied with great vigour.

One word in conclusion. As I have already observed on many previous occasions, ignorance of the principles of the real German system, and the "em-blems" of schools where they profess to do what they do not, will be a great obstacle to the public introduction of the system.

I remain, sir, your obedient servant, WILLIAM VAN PRAAGH.

164, Euston Road, N.W., 13 November, 1871.

•• We have received other communications confirming the above.

THE NATIONAL ORTHOPÆDIC HOSPITAL.—A series of readings and musical entertainments are being given at this hospital for the amusement of the patients, and in aid of the funds of this institution. The second entertainment took place at the Hospital on Wednesday evening last, the 15th inst. The programme consisted of vocal and instrumental music, and readings from various authors.

STRANGE, IF TRUE.—A rather equivocal account is given in the *Homeoed Mail* of a gentleman who is stated to have swallowed a snake while drinking a quantity of water. He was aware at the time that he had swallowed some foreign substance, and soon afterwards became restless and faint. A purgative was administered, which resulted in the passage of the offending animal.

## THE POOR-LAW MEDICAL SERVICE OF GREAT BRITAIN.

### MIDWIFERY FEES UNDER THE CONSOLIDATED ORDER OF THE POOR-LAW BOARD.

ACCORDING to Article 182 of the above order, it appears that, in cases in which any medical officer either for the workhouse or a district shall be called on by order of a person legally qualified to make such order to attend any woman in or immediately after childbirth, or shall, under circumstances of difficulty or danger, without any order, visit any such woman actually receiving relief, or whom the guardians may subsequently decide to have been in a destitute condition, such medical officer shall be paid for his attendance and medicines by a sum not less than 10s. nor more than 20s., according as the guardians may agree with such officer. It is provided by Article 183 that, in any special case in which great difficulty may have occurred in the delivery, any district medical officer shall receive the sum of £2.

The term childbirth, to which this order refers, is interpreted to apply only to those cases in which the child was or might be born alive. Hence the delivery of a seven months' child comes within the term childbirth. Attendance in a case of miscarriage, or in consequence of symptoms of premature labour, or if the woman were only four or five months gone with child, does not entitle the medical officer to the extra fee.

### FEES FOR CERTIFYING TO PAUPER LUNATICS.

DR. BOTHWELL of Woolwich has sent to the guardians a claim of one guinea for certifying to a pauper lunatic. The guardians state that other medical men have only charged half a guinea. The Chairman said that they should not pay a guinea for what they could get done for half the money. The certification of pauper lunatics is not included under the list of extra fees in the consolidated order of the Poor-law Board. The fee is not fixed by the Poor-law authorities; it is fixed by the magistrate or justice of the peace before whom the case is investigated. The customary fee is from one to three guineas, according to the trouble and difficulty of the case. The order for payment from the magistrate is imperative on the guardians. The terms of the clause under which provision is made for the payment of the medical man, in 8 and 9 Vict., c. 126, are as follows. The justices causing any person to be examined by any physician, surgeon, or apothecary, may make an order upon the guardians of the union or parish, or overseers of the parish, to which such person is chargeable, for the payment of such reasonable remuneration to any such physician, surgeon, or apothecary, for the examination of such person, and for all other reasonable expenses in or about the examination of such person. The lunatics that may be sent to a lunatic asylum by order of the justices, in pursuance of Stat. 8 and 9 Vict., cap. 126, are either lunatics chargeable to the parish from which they are sent, or wandering lunatics, or lunatics who are not chargeable, but are neglected or ill-treated by their friends. The medical officer of every parish and union, who shall have knowledge that any person chargeable is deemed to be a lunatic, shall give notice in writing to the overseer or relieving officer, and either the overseer or the relieving officer shall within three days give notice to a justice of the county or borough; and, if he neglect so to do, he is liable to a penalty of £10. The overseer takes the lunatic before the justice; and the justice calls to his assistance a physician, surgeon, or apothecary. Wandering lunatics are to be treated in like manner. Lunatics not chargeable, but neglected or ill-treated by their friends, must also be examined in like manner. Any medical officer, relieving officer, constable, or overseer, failing in their duty as expressed in this Act, incurs a penalty of £10.

### A DISPENSARY DOCTOR CALLED ON TO RESIGN.

A FEW weeks since, Mr. Horsley, Poor-law Inspector in Ireland, was authorised by the Commissioners to hold an inquiry into a charge brought against Dr. Spottiswood, the dispensary physician, and also the workhouse medical attendant at Cahirciveen, by the guardians of that union. The complaint was as follows. A man named Shea, belonging to the neighbourhood of that town, was returning from the Cahirciveen September fair, when he was thrown off his horse, a rather spirited animal, opposite the workhouse-gate. He was at once taken into the workhouse, and a messenger was despatched with a red ticket

to Dr. Spottiswood. The doctor refused to attend until the following morning. On his visiting Shea the following morning, he was dead. The circumstance was reported to the Board of Guardians in that town, and they communicated with Mr. Horsley, requesting him to hold an inquiry. On the receipt of the evidence, and of Mr. Horsley's report, the Commissioners have decided on calling on Dr. Spottiswood to resign. We understand that the guardians are getting up a memorial to the Commissioner asking him to withdraw the request.

ASSOCIATE (Carmarthen) asks whether a certificate of proficiency in vaccination is a *sine quâ non* for an M.R.C.S. and L.S.A. applying for an appointment under the Poor-law Board? By looking in the *Medical Directory*, our correspondent will see at page 952 the list of authorised persons, and the nearest place at which it can be obtained.

## OBITUARY.

### JOHN SAMUEL SNOOK, M.R.C.S.L., COLYTON, DEVON.

MR. J. S. SNOOK died on October 15th, at Colyton, where he was well and favourably known as a practitioner. As a student at the Middlesex Hospital, his career was highly creditable; and on the completion of his studies, thirty-two years since, he settled in his native place, where with uniform success and credit he carried on a large country practice till his death, at the age of 57. The estimation in which he was held has been shown by the universal sympathy and respect manifested to his memory and towards his widow and family.

### FREDERICK COOKE, M.R.C.S., ASHTON-UNDER-LYNE.

IT is our painful duty to record the death of Mr. Frederick Cooke, of Ashton-under-Lyne, which happened on Thursday, October 19th. Mr. Cooke was in his sixty-first year. He was a native of the township of Denton, and was apprenticed to Mr. Cheetham, surgeon, of Ashton. He became a student at Grainger's School, and at Guy's and St. Thomas's Hospitals. He obtained the diploma of Member of the Royal College of Surgeons and the licence of the Apothecaries' Society in 1832. Mr. Cooke practised as a surgeon in Denton for about ten years, and during this period he married a sister of Mr. Cheetham. On the death of Mr. Cheetham in 1843, Mr. Cooke removed to Ashton; and in 1846 was appointed Medical Officer for the No. 10 District, which office he energetically filled up to the time of his decease.

Mr. Cooke was recognised in his own immediate locality as a surgeon of great ability, and his kind and sympathising manner to his patients earned for him a name which will long be remembered. His practice in Ashton and the neighbourhood became very extensive; and, although his constitution was very strong, the labour of a professional life impaired it, the result being a severe attack of hæmatemesis, from which he never entirely recovered. For the last three months he complained of a pain at the base of the left lung, and had some difficulty in breathing. He was, however, able to carry on his duties, with the assistance of his son, to October 12th, when he was compelled to remain at home. On the following morning, acute pleuropneumonia set in. He was visited by Dr. S. D. Lees of Ashton, and Dr. Simpson of Manchester; but their efforts were unavailing.

In 1862, Mr. Cooke was elected a member of the Town Council. Although a strong politician, he always took an independent part, and was never known to oppose any measure which might be calculated to conduce to the real welfare and benefit of the inhabitants of the borough at large.

### CALEB WILLIAMS, M.D., F.R.C.S., YORK.

DR. CALEB WILLIAMS died on November 5th, after an illness of a few days, at the age of 72. His early professional education was under Dr. Travis, of Scarborough. He afterwards attended Guy's and St. Thomas's Hospitals in London, and spent a short time in Paris. At the age of 25 he commenced practice in York; in the same year he was chosen as Visiting Medical Officer to the Friends' Retreat. On the ground of declining health, he resigned this appointment in April 1871. In 1864, he succeeded Dr. Thomas Simpson as Consulting Physician to the York County Asylum. From 1838 to 1858 he was Lecturer on *Materia Medica* and *Therapeutics* in the York School of Medicine. Dr. Williams had a large experience in the treatment of the insane. He advocated a wide application of the plea of insanity in criminal cases. In 1856, he made known his opinions on this subject in a work on *The Criminal Responsibility of the Insane*. Dr. Williams's course as a practitioner was one of constantly increasing reputation. His skill and judgment in his medical career, of which his success is some guarantee, was united with

refinement, courtesy, and gentleness of manner, that made him a favourite with his patients and their friends. His character as a Christian gentleman was well known. He cordially united with his fellow-citizens in support of the numerous philanthropic, benevolent, and educational institutions in York. The County Hospital, the Dispensary, and the Penitentiary were especial objects of his interest and care. For forty years he was a preacher in the Society of Friends.

JOHN HANCOCK, M.R.C.S.E., L.S.A., WEDMORE,  
SOMERSETSHIRE.

It is with regret that we announce the death of Mr. John Hancock, surgeon, who died on November 6th, after one week's illness. In 1834, he was appointed medical officer for the parish of Allerton; and, upon the formation of the new Poor-law arrangements, he had other parishes in addition placed under his charge. Finding the work too heavy, he resigned part of his district, but retained the remainder until 1849, when he resigned on account of insufficiency of salary. A vacancy occurring in 1854, he was reappointed at an increased salary, and continued to attend the poor until 1867. His professional skill was great, and his kindly genial manner endeared him to all; and his loss is deeply felt. His patients and friends were getting up a testimonial for him at the time of his death, as a token of respect and regard. He has left a widow and one child.

## UNIVERSITY INTELLIGENCE.

### UNIVERSITY OF CAMBRIDGE.

**SCHOLARSHIPS.**—Trinity College offers one or more scholarships of the value of £80 a year for Natural Science. The examination will be on April 5th, open to all persons under the age of 21.—St. John's College offers an exhibition of £50 a year. The examination, on April 12th, in Chemistry, Physics, and Physiology, will be open to persons under 20 not members of the University, and to under-graduates in their first term. The tutors of the College will supply further information.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on November 14th.

Adams, Robert, Gurnislake, near Tavistock (University College)  
Atkins, Francis Grant, Barbadoes (St. Mary's)  
Baizer, Edward Cresswell, Thurlow Square, Brompton (St. George's)  
Barlow, Thomas, Greenhorne, near Manchester (Manchester School)  
Biggs, Moses George, Welford, Northamptonshire (University College)  
Davies, Arthur Evelyn, Newport, Monmouthshire (University College)  
Dawson, John Lucius, Wandsworth (Dulwich School)  
Giffard, Douglas William, Guernsey (St. Bartholomew's)  
Goldrich, Alfred, Fulham Road (St. George's)  
Hammond, Robert Edward, St. Helen's, Lancashire (Manchester School)  
Hayes, Aylmer Ellis, Tavistock Crescent (St. Mary's)  
Hill, Thomas Wood, South Kemington (St. George's)  
Hudson, William Edward, Bishops Stortford (Charing Cross)  
Jackson, James, Wotton Bassett (St. Thomas's)  
James, William Dale, Yong Park, Islington (Sheffield School)  
Lang, John Meunier, Thatcham, Berks (St. George's)  
Lawrence, Henry, Clifton, Somerset (Bristol School)  
Lyth, John Burdall, Sheffield (Liverpool School)  
Maisey, Frederick Thomas, Cheltenham (Guy's)  
Marshall, John, Boleyn, Sussex (Guy's)  
Moss, James Henson, Manchester (Manchester School)  
Newberry, William John, Liverpool Road (St. Bartholomew's)  
Price, Charles William, Mersey Tyddil (University College)  
Raines, Charles, Hull (Hull School)  
Ramsay, Charles, Macclesfield, Somerset (Bristol School)  
Seymour, Francis, O'Brien, Hants (Guy's)  
Simons, David Alexander, London, Canada West (Toronto School)  
Thompson, Henry, Hull (Hull School)  
Toss, Thomas, Larch, Warwick (Guy's)  
Tucker, Francis, Cambridge, M.A. Cambs. (Guy's Hospital (Guy's))  
Walker, Frank, Underwood, Kent (Guy's)  
Walker, Robert, Melbourne, Australia (St. George's)  
Wells, Charles Robert, Easingwode (King's College)

The following candidates were admitted members on November 15th.

Baker, Thomas, Birmingham (Birmingham School)  
Beck, Louis, Guy's (Guy's)  
Bridgman, Henry Edward, London, Kingsbridge, Devon (St. Bartholomew's)  
Cameron, John Alexander, York Road (King's College)  
Carbone, William, Boston (Boston School)  
Compton, Sydney, Southampton, Surrey (University College)  
Duke, Douglas William, Upper Norwood (Guy's)  
Dustin, Henry, Jersey (University College)

Elliott, Frederick William, Turnham Green (University College)  
Hosking, Ethelbert, Woburn Square (King's College)  
Jackson, Thomas William, Leyland, Lancashire (Guy's)  
Kilner, Walter John, Bury St. Edmunds (St. Thomas's)  
Mackenzie, Lewis, Dreadnought Hospital Ship, Deptford (London)  
Meredith, William Henry, Netherton, near Dudley (Birmingham School)  
Parnell, Gerald Crecy, Sussex Place, Regent's Park (St. Bartholomew's)  
Richmond, Onslow Robert, Hornsey (King's College)  
Thane, George Dancer, jun., Montague Street (University College)  
Wall, William Barrow, Wedmore, Somerset (University College)  
Wesley, William Ken, Gloucester (St. Bartholomew's)  
Wheeler, Daniel Martin Brumwell, Chelmsford (Guy's)

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, November 9th, 1871.

Graham, George William, Winchester  
Mayne, Thomas, Devonport  
Seymour, Francis, Odiham

The following gentlemen also on the same day passed their first professional examination.

Edwards, Alfred, University College  
Griffith, William Edwin, Middlesex Hospital  
Hawthorn, William Thomas, London Hospital  
Woodward, George, St. George's Hospital

As an Assistant in compounding and dispensing medicines.  
Wolf, Edward Parker, Evelina Hospital, Borough

### MEDICAL VACANCIES.

THE following vacancies are announced:—

BALFORTH, Stirlingshire—Parochial Medical Officer.  
BIRMINGHAM AND MIDLAND EYE HOSPITAL—House-Surgeon.  
BISHOP STORTFORD UNION—Medical Officer for the Braughing District: £35 per annum.  
BOSMERE and CLAYDON UNION, Suffolk—Medical Officer for the Claydon District: £42 per annum.  
CHARING CROSS HOSPITAL—Surgeon-Dentist.  
DERBYSHIRE LUNATIC ASYLUM, Mickleover—Superintendent-Physician: £400 per annum, lodgings and rations.  
ENNISCORTHY UNION, co. Wexford—Medical Officer for the Oulart Dispensary District: £115 per ann., Vaccination and Registration Fees, and residence.  
EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge Road—Medical Registrar.  
GENERAL HOSPITAL, Birmingham—House-Governor and Secretary: £200 per annum, board and residence.  
KENT AND CANTERBURY HOSPITAL—House Surgeon: £80 per annum, board, lodging, and washing.  
LINCOLNSHIRE—Medical Officer for the County Gaol for the parts of Lindsey: £120 per annum.  
LIVERPOOL ROYAL INFIRMARY—Physician.  
MOUNTMELLICK UNION, Queen's County—Medical Officer for the Coolrain Dispensary District: £50 per annum, and Registration and Vaccination Fees.  
PORTSEA ISLAND UNION—Medical Officer for the Landport District: £70 per annum.  
REETH UNION, Yorkshire—Medical Officer for the Muker District: £32:10:0 per annum, and extra fees.  
ROYAL INFIRMARY, Aberdeen—Physician.  
ROYAL INFIRMARY, Edinburgh—General Superintendent: £420 per annum, and house rent.  
ST. MARY'S HOSPITAL AND DISPENSARY for WOMEN and CHILDREN, Manchester—Medical Officer.  
SLIGO UNION—Apothecary to the Sligo Dispensary: £50 per annum.  
SOUTH STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton—Physician's Assistant: £100 per ann., with board, washing, and furnished apartments.  
SUSSEX COUNTY HOSPITAL, Brighton—Surgeon: Assistant-Surgeon.  
TEIGNMOUTH, DAWLISH, and NEWTON DISPENSARY and INFIRMARY—House-Surgeon: £50 per annum, and board and lodging.  
VICTORIA HOSPITAL FOR SICK CHILDREN, Chelsea—House-Surgeon.  
WEM UNION, Salop—Medical Officer for the Prees District: £40 per annum.  
WESTHAMPTON UNION, Sussex—Medical Officer and Public Vaccinator for the Rumboldswyke District: £100 per annum, and extra fees.

**ERRATUM.**—By an accidental confusion of names, it was recently stated, incorrectly, that District No. 1 and the Workhouse of the Pewsey Union were vacant: there is no change in the appointments in question.

### MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

\*BOTTLER, Alex., M.D., appointed Resident Physician to the Birmingham General Dispensary, *vice* C. W. Philpot, M.D., resigned.  
GRANT, Hugh, L.R.C.S. Edin., appointed Medical Officer for the Parishes of Darnley and Dumbellity.  
LEWIS, William, M.D., appointed Physician to the Finsbury Dispensary, *vice* Wm. Abbott Smith, M.D., resigned.  
PHILLIPS, Alfred, Esq., appointed Resident Medical Officer to the Finsbury Dispensary, *vice* J. L. May, Esq., resigned.  
SHEPHERD, Michael J., M.D., elected Medical Officer for the Wexford Dispensary District of the Wexford Union, *vice* Robert J. Furlong, L.R.C.S. Irell, deceased.

**ADDENBROOKE HOSPITAL, CAMBRIDGE.**—The annual audit shows an excess of expenditure over income amounting to £682:8:5.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY** ..... Metropolitan Free, 2 P.M.—St. Mark's, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**TUESDAY** ..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—National Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**WEDNESDAY**.. St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 2 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**THURSDAY**.... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

**FRIDAY**..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic Hospital, 2 P.M.

**SATURDAY**... St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Lock (Clinical Demonstrations and Operations), 1 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Free, 2 P.M.—East London Hospital for Children, 2 P.M.—Hospital for Women, 9.30 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY**.—Medical Society of London, 8 P.M. Dr. Prosser James, "On Oæna." An adjourned discussion on Dr. Alfred Carpenter's paper on the Two Cases of Muscular Anæsthesia. Mr. Spencer Watson's Case of Skin-grafting under Continuous Irrigation.

**TUESDAY**.—Pathological Society of London, 8 P.M. The following specimens will be exhibited:—Dr. Dickinson, Intracranial Aneurism the cause of Sudden Death; Dr. Bäumer, Aneurism of the Innominate Artery, compressing the Pneumogastric Nerve; Dr. Hawkes, Horse-shoe Kidney; Mr. Spencer Watson, Ulcer of the Lower Eyelid removed by Dr. Swift Walker; Mr. H. Arnott, Results of Excision of the Elbow-joint.

**WEDNESDAY**.—Hunterian Society, 8 P.M. Dr. Ward, "On Cases illustrating the Sequæ of Ague and Malarious Remittent Fever."—Society of Arts, 8 P.M. Mr. Hyde Clarke, "On the Present State of the Through Railway Communication to India."

**FRIDAY**.—Quekett Microscopical Club (University College, Gower Street), 8 P.M. Mr. M. C. Cooke, M.A. "On the Tremeloid Uredines."—Clinical Society of London, 8.30 P.M. Dr. Glover, "A Case of Uncomplicated Aphasia"; Dr. Moxon, "On Symptoms of Cranial Tumours destroying Nerves cured by Iodide of Potassium"; Dr. Habershon, "On Cases of Heart-disease." Also, papers by Dr. Anstie and Dr. Ogle.

## NOTICES TO CORRESPONDENTS.

**ALL Letters and Communications for the JOURNAL, to be addressed to the EDITOR, 37, Great Queen Street, Lincoln's Inn Fields, W.C.**

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**TO PURCHASERS**.—To insure attention, it is requested that all orders sent to the Office for extra copies of the JOURNAL, be accompanied with halfpenny stamps for the amount.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**FOR** replies to questions concerning Poor-law medical questions, see Poor law Medical Department, under charge of Mr. Benson Baker, London, and Dr. Maunsell, Dublin.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

**COLLECTION OF SUBSCRIPTIONS**.—Dr. Colville Brown (Berwick-on-Tweed) writes:—"Perhaps you are quite right in saying that 'I should have received four circulars'; but you are quite wrong when you say 'I have no doubt received them.' We are sorry to hear it; the applications should have come from the General Secretary, Dr. Brown not belonging to a Branch.

**MR. HILL'S** communication as to operations at the West London Hospital, arrived too late.

**DR. W. NEWMAN** (Stamford).—With pleasure. *Quanto plus brevitatis, tanto plus gratia.*

**VOMITING IN PREGNANCY**.—In a recent number we referred to a memoir by M. Hubert on Vomiting in Pregnancy. At the Obstetrical Society, on April 5th, 1871, Dr. Graily Hewitt read a paper on the same subject. He appears to have anticipated M. Hubert. An abstract of his paper was given in No. 538 of the BRITISH MEDICAL JOURNAL.

**ALUNNUS**, St. Bartholomew's.—Yes, to both questions.

## THE BROWN HOSPITAL.

**WHEN** J. N. N. next comes to town, he may be more successful in his search. Our contemporary was wrong in placing the hospital in the Walworth Road. It is in the Wandsworth Road, where it is in operation. We shall, at the proper time, give some further account of it. We regret J. N. N.'s mishap, but we are not responsible for other people's errors. He has addressed his complaint to the wrong office.

**NOTICE TO ADVERTISERS**.—Advertisements should be forwarded direct to the Printing-Office, 37, Great Queen Street, W.C., addressed to Mr. F. H. HEATHCOTE, not later than *Thursday*, twelve o'clock.

## CAUTION.

It having come to the knowledge of the Publisher that circulars have been distributed calculated to mislead advertisers as to the circulation of this journal, he feels it incumbent on him to state that its circulation far exceeds that of any other medical periodical, and that it has for many years past steadily increased, and is still increasing.

**EXEMPTION FROM JURIES**.—For the satisfaction of Dr. Haynes, I may state that, though not registered, physicians, surgeons, and apothecaries, actually practising, are exempted from serving on juries, by 6 George IV, c. 40.—B. W. LARA, London.

## FEES AT INQUESTS.

**SIR**.—With reference to your reply to Dr. Haining in the JOURNAL of October 28th, about House-Surgeons and Fees for Necropsies, I beg to inform you that I forwarded a copy of it to our borough coroner, requesting a fee of £1:1 for a *post mortem* examination, made at his request, upon the body of a patient who recently died in this hospital. He replied, that the Act gave him no authority to pay me for my work, as it was not for his information, but to enable me to tell the jury the cause of death. Will you kindly inform me, through your columns, if I could legally recover in a County Court, as the coroner gave me a very unsatisfactory and evasive answer to your reading of the Act?

I am, etc., GEO. S. ELLISTON, House-Surgeon.

East Suffolk Hospital, Ipswich, November 1st, 1871.

\*. The answer of the coroner in this instance is clearly not satisfactory. All information by an expert is for the information of the jury and not of the coroner. Having performed the inquest in this instance, without previous notice that he should require a fee for doing it, we do not think Mr. Elliston would be wise to push the matter further. The question should be raised when the order is given: raised courteously, but fairly. Whenever the coroner requires a duty to be expressly performed for the information of his jury, he ought to pay for it. If the *post mortem* examination has already been performed as part of the routine duty of the hospital, he clearly cannot and ought not to pay for it. This is not an authoritative reading of the law; but it is a question which may fairly, we think, be raised.

## INSTITUTE OF ANATOMY.

**SIR**.—A patient of mine was foolish enough to send his six guineas to the Institute of Anatomy, conducted by Dr. Hunter, and took the medicine for the prescribed time of eight weeks. As the only complaint which he had was a little nervousness, he naturally found himself no better at the end of the eight weeks than he was at the beginning, but, fortunately for him, he was no worse. As the doctor required another fee to continue the treatment, my patient thought better of it, and came to me to show me the enclosed letter, which I send, because I think it a good specimen for publication.

I am, etc., AN ASSOCIATE.

October 30th, 1871.

"44, Great Charles Street, Birmingham, April 27th, 1871.

"Dear Sir,—We are in receipt of your favour and enclosure, for which we now offer you our best advice under the peculiar circumstances of your case. It is with much pleasure we can inform you that, although you have done yourself considerable injury by the practice you speak of, the evil is not irreparable, and its direful results may be entirely prevented by the employment of a course of remedies which, during our extensive and, we may confidently say, highly successful practice, we have never yet known to fail when our patients have implicitly abided by our instructions; much depends upon the firmness of the patient himself; and if you will rigorously conform to our instructions, the results will realise your most sanguine hopes. The bottle containing the urine we duly received, and have submitted the same to a very careful examination; and we readily and at once, by the aid of the microscope, detected the spermatozoa in the urine in large quantities, and are of opinion that the semen has been unnaturally escaping in the same way for a considerable time. The effect this would have upon the generative system ultimately would be a gradual wasting of those organs, which would cause impotency, and the least excitement would occasion the loss of your virile power, which, as no doubt you are aware, has a very debilitating effect upon the whole frame, bringing on palpitation of the heart, nervousness, and other organic diseases, because your system is deprived of that support which nature requires. The seat of your disease is in the seminal ducts or vessels conveying the seed from the testicles, which have become weakened by the practice mentioned, and are unable to retain their contents, the mouths of these vessels opening into the urethra behind the prostate gland have become enlarged, and the semen escapes in the manner described. The removal of these symptoms cannot, however, be effected in a day or a week; but if you place yourself under our care for about eight weeks, we have not the least doubt of effecting a permanent cure; our usual fees for which, in cases like your own, are six guineas, which sum includes consultations, remedies, etc. On receipt of this amount by post-office order or otherwise, we will forward full instructions for your subsequent guidance, together with the necessary supplies of the remedies. In the course of treatment we adopt, no particular change of diet is necessary, neither is it requisite to neglect business, nor alter the general habits of life. No deleterious ingredients are employed by us, but the cure will be imperceptibly, safely, and surely effected by the remedies we administer. The medicine we now send is for the purpose of preparing your system for the peculiar alternatives and tonics we intend to employ; and we feel satisfied that in a short time we shall deserve, and we trust receive, your heartfelt thanks for our exertions in promoting your temporal happiness, and ridding you of those distressing feelings of which you now complain. The dose of the medicine is one tablespoonful three times a day; the first and second doses to be taken half an hour before breakfast and dinner, and the third the last thing at night, which will prepare your system for the remedies described. Awaiting your reply,

"We are, yours faithfully, J. & W. HUNTER."

**SIR**.—Will you permit me to inquire if there is any gentleman in London who will undertake to assist a country medical man in preparing for the fellowship examination? The writer of this notice, having been in active practice for several years, has got rusty in anatomy and physiology, and wishes an opportunity of acquiring a practical knowledge of the subjects examined in.

November 9th, 1871.

I am, etc.,

ASSOCIATE.

**NOTICES of Births, Marriages, Deaths, and Appointments, intended for insertion in the JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.**

**ANALYSIS OF WATER.**—Sir: A Poor Curate is, I fear, suffering from the effects of impure water. I cannot analyse the water, and he is unable to pay a large fee for so doing. Will any of your readers inform me how or where I can get it done cheaply? Address Mr. Chas. M. Thompson, Sevenoaks.

**ERRATUM.**—In the article on "Abdominal Puncture in Tympanites," Nov. 11th, page 563, the tenth line of the extract from Sir Thomas Watson's Lectures, the word "impossible" is a misprint for "improbable."

#### SUBCUTANEOUS FOREIGN BODIES.

**SIR.**—As the following cases appear somewhat difficult of explanation, I shall feel obliged if you can find space for their insertion in your JOURNAL; and I shall be happy to learn the opinion of any of your readers respecting them, and to ascertain whether similar instances have been met with.

About sixteen years ago, I was requested to see a child, three years old, who had a small swelling in the calf of one of the legs. On examination, I found there was something movable under the skin; and, on making a small incision, a little serum escaped, when I extracted an entire crochet-needle. The parents could offer no explanation of the case; they had never known the child to complain of any pain, and had never observed any lameness. There was no external wound before I made the incision; and as a little serum then escaped, the needle was, no doubt, encysted, and had probably been *in situ* for some time. How had it entered? It could hardly have penetrated the skin and become imbedded subcutaneously without considerable force, which must have caused pain and lameness that could not have escaped the notice of those having the care of the child. Although needles have been known to pass some distance from the part where they have originally entered, yet one can scarcely suppose that this crochet-needle was accidentally swallowed, and then passed from the stomach to the place where it was found, as it could not have traversed the hip and knee-joints without causing much lameness.

Soon after this case occurred, I saw a schoolboy, about ten years old, who had a small swelling in his left side near the sternum. I readily detected some foreign body under the skin; and, on making an incision, a sewing-needle was extracted. In this case, there was no external wound when I saw the boy; he had no recollection of a needle having entered the skin, and had had no pain until just before I saw him. When his mother was informed of the occurrence, she said that she remembered having swallowed a needle when pregnant of him, which she had never seen afterwards. In this case, I suppose the needle must have passed from her stomach into the gravid uterus, and thence into the child, where it remained for some years without its presence being revealed.

Two months ago, an infant, aged six weeks, was brought to me on account of a small swelling near the left nipple. I was told that, a day or two previously, the child, until then quite well, had appeared feverish and restless, as if in pain, and a few hours before I saw it, the swelling in the side was observed. As there was evidently something under the skin, I made an incision, when I extracted a darning-needle, measuring two inches in length. Neither the mother nor nurse had any recollection of a needle having entered the child; and there was no wound, or mark of one, when it was brought to me.

I am, etc.,

JAMES ORWIN, M.D.

Granville Terrace, Notting Hill, October 1871.

**BRITISH MEDICAL BIBLIOGRAPHY,** by Dr. KENNEDY, late of Ashby-de-la-Zouch. This work was promised to the members of the Old Sydenham Society in the 1849 Report. Has it been published? if so, when and where?—G. S. S.

#### ROYAL COLLEGE OF SURGEONS.

The following were the questions submitted to the candidates at the primary examination in Anatomy and Physiology. 1. Describe the Anatomy of the Colon, including its minute structure. State its position in reference to the exterior of the abdomen; and mention the internal parts and structures with which it is in close relation.—2. State how the first act of Breathing is induced in the New-born Infant, and explain the physiological effects of respiration.—3. Describe the dissection required to expose the Internal Maxillary Artery; then give its course, relations, and branches in the order in which they arise, and their distribution.—4. Give the position, attachments, and function of the Ciliary Muscle. Describe its microscopic structure.—5. Describe the Os Hyoides, and mention the muscles and ligaments connected with it; and state the nerves by which the former are respectively supplied.—6. Enumerate the various Excretions. Give the principal constituents of each, their mean amount in the healthy adult subject in twenty-four hours, and the sources whence each of these constituents is derived.

The following were the questions on Surgery, etc. 1. Describe the action of a ligature and of torsion in arresting hæmorrhage from a severed artery; and state what is the effect of a ligature upon an undivided artery, as in an operation for Anæsthesia; and how the continuity of the artery is permanently interrupted after the separation of the ligature.—2. Give the Surgical Anatomy of the Ulnar Artery as far as the wrist; and describe the operation for its ligation in the middle of the forearm, indicating the precise relations of the vessel at the point at which it is tied.—3. Describe the symptoms, consequences, and treatment of chronic enlargement of the Prostate Gland.—4. Mention the different tissues and localities in which the formation of Pus causes the greatest local pain and constitutional disturbance. State giving examples the circumstances that would induce you to operate as early as possible, and those in which delay or non-interference would be preferable.—5. Describe the deformity produced by simple Dislocation of the Foot outward at the ankle; mention the structures which are necessarily broken or lacerated in this accident. State the mode of reduction and the means you would have recourse to under circumstances of unusual difficulty.—6. Mention the various kinds of Cataract; give the diagnostic characters of each, and state the usual conditions under which the different forms occur; and describe the operation of Extraction.

The following were the questions on the Principles and Practice of Medicine. 1. A day or two after exposure to cold, a patient is taken with feverishness, difficulty of breathing, and weakness at the chest. What are the different forms of disease which may possibly be occurring, and how would you severally distinguish them?—2. What are the chief deposits which may be found in the urine? Under what circumstances do they severally occur? and how would you recognise each form?—3. Mention the remedies which are commonly described as *nervina* *tonica*, and state in what cases you would use them, and the doses in which they may be given.—Write a prescription for the exhibition of one of these medicines.

**SIR.**—Can you or any of your correspondents inform me what books to study on the manufacture, and mode of fixing in the mouth, of artificial teeth?

Byers Green, November 13th, 1871.

I am, etc., G. O. McKANE.

**H. A. B.**—We have read attentively, since receiving our correspondent's communication, the article to which he refers. It is not at all surprising that our contemporary should, under the circumstances, be ignorant of its part, and oblivious of its endorsement of the suggestions with which it now asserts it did not coincide. But the careless ignorance displayed in the course of the article is to be regretted. It involves a gross injustice to the many eminent men, medical and others, who have, at a heavy sacrifice, devoted an unusual combination of skill and varied knowledge to a work of charity, which, under great difficulties, they administer with singular success and with ability of which all the skilled critics who really witnessed the result have testified their warmest admiration.

**DR. MARKHEIM (Paris) and Dr. CHRISTIE (Ealing)** are requested to complain to the Post-office authorities. Their journals are duly posted. Some four thousand journals are weekly transmitted by post from this office. This work is a great labour which, so far as our inquiries enable us to judge, is performed with conscientious care. An average failure of arrival occurs in about one per thousand. Sometimes, however, a marked carelessness is shown by the Post-office officials at particular places; and we are always desirous of being kept informed of the instances in which the journals are not carefully delivered. In the metropolis, an extensive hand-delivery is organised; and part of our circulation passes through the hands of agents. In any case, it is requested that complaints of want of punctuality may be made to the chief office, 37, Great Queen Street, London, W.C.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Shrewsbury Chronicle, Nov. 10th; The Dudley Guardian, Tipton, Oldbury, and West Bromwich Journal, and District Advertiser, Nov. 11th; The Brighton Herald, Nov. 11th; The New York Tribune; The Liverpool Albion, Nov. 13th; The Morpeth Chronicle; The Irish Times; The Deptford Chronicle, Nov. 11th; The North British Daily Mail, Nov. 14th; The Isle of Man Times; The Freeman, Nov. 11th and 12th; The Irish Times, Nov. 11th and 12th; Saunders's News, Nov. 11th and 12th; The Dublin Evening Telegraph; The Liverpool Albion, Nov. 11th; The Croydon Times; The Brighton Advertiser; The North Middlesex Advertiser; The Edinburgh Courant, Nov. 14th; etc.

#### COMMUNICATIONS, LETTERS, ETC., have been received from:—

Dr. W. Stokes, Dublin; Dr. Wilks, London; Mr. Husband, York; Dr. George Johnson, London; Dr. Sansom, London; Mr. Hill, London; Mr. Dalby, London; Mr. Augustin Pritchard, Clifton; Dr. E. Symes Thompson, London; Mr. P. Le Neve Foster, London; Dr. H. Barnes, Carlisle; Dr. Kidd, London; Our Dublin Correspondent; Dr. Hilliard, Glasgow; Dr. Althaus, London, The Secretary of the London Institution; Dr. Behrend, London; Dr. G. H. Philipson, Newcastle-upon-Tyne; Mr. Chas. Steele, Bristol; Dr. F. J. Brown, Rochester; The Secretary of the Manchester Medical Society; Dr. Wm. Roysds, Reading; The Secretary of the Clinical Society; Messrs. Johnson and Sons, London; An Associate; Dr. Bryan, Northampton; Mr. H. J. Broom, Pembrey; Mr. T. Watkin Williams, Birmingham; Dr. Shapter, Exeter; Mr. Bartlett, Birmingham; The Secretary of the Hunterian Society; Dr. G. Symes Saunders, Exminster; Our Vienna Correspondent; Mr. T. Charters White, London; Mr. Van Praagh, London; Dr. John Ogle, London; Dr. Martin, Stoneyhavan; Dr. John Dougall, Glasgow; Dr. Maunsell, Dublin; Dr. Morley Rooke, Cheltenham; Dr. Newman, Stamford; Dr. A. T. H. Waters, Liverpool; Mr. Andrews, Plymouth; Major Leicester, London; Dr. Christie, Ealing; Dr. Markheim, Paris; Dr. Styrap, Shrewsbury; Dr. Brown, Berwick-on-Tweed; Dr. Finney, Dublin; Dr. B. W. Foster, Birmingham; Dr. Meadows, London; Dr. Percy, London; Mr. Thompson, Sevenoaks; A Member of the Association; Mr. Robert Freeman, London; The Registrar-General of England; The Secretary of Apothecaries' Hall; The Registrar-General of Ireland; Mr. T. M. Stone, London; The Registrar of the Medical Society of London; Mr. St. George Mivart, London; The Secretary of the Pathological Society; Mr. Osman Vincent, London; Mr. Milner M. Moore, Devonport; Dr. Bruce, Glasgow; Mr. A. Matthews, London; Mr. J. M. Hobbay, Aylesbury; Dr. Wrangham, Wragby; Mr. Abbott, Earls Colne; Mr. Bradford, Bournemouth; Mr. B. Browning, Littlebourne; Dr. J. H. Balfour, Edinburgh; Dr. Thorowgood, London; Mr. Barber, Manchester; Dr. Ritchie, Edinburgh; Mr. Hinton, Warminster; Our Berlin Correspondent; Our Leeds Correspondent; Miss Murphy, London; Mr. Campbell De Morgan, London; Mr. Hulke, London; Mr. Erichsen, London; Dr. A. Hollis, Dorchester; The Editor of the "Pharmaceutical Journal"; Mr. Benson Baker, London; Mr. Gray, London; Dr. Jagielski, London; Dr. Grimshaw, Dublin; Mr. G. F. Weston, Stafford; The Secretary of State for India; Dr. Turnbull, Bombay; Dr. Bottle, Wolverhampton; Dr. Parsons, Dover; Dr. Roberts, Chester; Dr. J. N. Vinen, London; Mr. H. G. Hardy, Byers Green; Mr. J. Waley, Stoney Stratford; Our Paris Correspondent; Dr. A. B. Steele, Liverpool; Mr. Fleischmann, Cheltenham; Dr. S. Haynes, Malvern Link; etc.

#### BOOKS, ETC., RECEIVED.

The Seventh Annual Report of the Tewkesbury Rural Hospital, 1871.  
Monthly Report on the Health of the Parish of St. Marylebone during October 1871. By John Whitmore, M.D.  
The Water-Supply of London: a Speech delivered in the House of Commons, May 2nd, 1871. Also, a Preface to the Metropolitan Water Act. By N. J. Kay-Shuttleworth, M.P. To which is appended, by permission, a Speech delivered on the same Debate. By Dr. Lyon Playfair, C.B., M.P., F.R.S. London: 1871.  
Notes on the Treatment of Skin-Diseases. By Robert Living, A.M., M.D. Cantab. Second Edition, with Additions. London: 1871.  
Report on Vaccination throughout the Bombay Presidency and Sind for the year 1870-71. Bombay: 1871.

## RETROSPECTIVE ADDRESS

OF THE

## PATHOLOGICAL SOCIETY OF READING.

*Read September 27th, 1871.*

By WILLIAM ROYDS, L.R.C.P.Lond.

MR. PRESIDENT AND GENTLEMEN,—I have not the presumption to undertake, without misgiving, the honourable task which your kindness has paid me the high compliment of imposing. To give an appropriate *résumé* of the proceedings of your Society for the past year, to review your papers and discussions, and fairly to recriticise your criticisms of the various subjects which have been brought before you, would require much greater knowledge and experience than I, a young member of your Society, can pretend to; and when I look back upon the long list of the names of those who have ably performed the duty which now devolves upon me of delivering the retrospective address to this the oldest Pathological Society in England, I feel that I must crave your indulgence whilst, to the best of my ability, I endeavour, by recapitulating the work of the past session, to perform the task which shall add my name to the roll.

The session 1870-71 has been in many respects a successful one. The meetings have been well—I believe, unusually well—attended, and the papers and discussions have not lacked interest; although I am struck, on looking through the list, at the scarcity of subjects having an interest purely medical, and venture to think that more of our time might profitably be devoted to medicine in the more limited application of the term, and especially in endeavouring to aid in filling up the “greatest gap” in the science, namely, that to be found “in its supreme and final stage,” “the stage of therapeutics.”

The variety of the past session has not been great, and I think I may best adopt the somewhat crude classification of medical, surgical, and obstetric subjects, and shall then have a few cases or papers which do not aptly fall under any of these heads, and to which I must refer as miscellaneous.

**I. MEDICAL CASES.**—*Cancer of the Brain.*—Dr. Reid read the following interesting case, illustrated by the specimen which he presented. The patient was a female, aged 34. In May 1870 she underwent, at the hands of Mr. Weeden Cooke, an operation for the removal of a cancerous tumour of the breast. The wound healed, and all seemingly went well with her until the beginning of August, when she was suddenly seized with loss of power in the right side and defect of speech. These symptoms passed off, but recurred with violent headache at the beginning of September. Another remission took place, leaving, however, impairment of speech, and persistent dull headache. In the beginning of October she suffered another attack of hemiplegia with aphasia. The symptoms became more and more intensified, the right arm ultimately remaining in a state of rigid flexion, and she died on December 2nd. The periods at which marked aggravation of the symptoms was noticed in each instance immediately preceded the appearance of the catamenia. On examining the brain after death, two deposits of cancerous matter were found in the surface and in the substance of the left cerebral hemisphere; each was about the size of a pigeon's egg, and the anterior one occupied the third left frontal convolution. The case thus formed an interesting addition to the rule of the production of aphasia by a lesion so situated. It is said to be rare to find more than one adventitious deposit in the brain; and where more than one exist, they are usually symmetrical. In this case it was not so. The nature of the disease had been diagnosed by Mr. May, and the situation of the deposit had been correctly predicted.

*Aneurism of the Aorta: Tracheotomy.*—The next case is one usually classed as a medical case, but in which surgical treatment was adopted unfortunately too late to be of much avail in prolonging life. A paper was read by Mr. Crisp on a case of aneurism of the aorta. H. D., aged 39, an officer's groom, consulted Mr. Crisp for an illness, which he stated to be of some weeks' duration, and to have commenced with cold, difficulty of breathing, alteration of voice, and cough. At the time when Mr. Crisp saw him he was in a very depressed and nervous state, unable to speak beyond a whisper; his voice, cough, and breathing, were markedly laryngeal. The left side of the thorax, anteriorly and superiorly, was more prominent than the right. There were deficiency of respiratory movements, and increased præcordial dulness. The

breath-sounds were especially deficient, posteriorly and superiorly, on the left side. From the symptoms, Mr. Crisp judged that an intra-thoracic tumour, probably an aneurism, existed. The same evening the patient was seized with a sudden and violent attack of spasmodic breathing. This passed off, to recur several times within the next forty hours, the last attack leaving him in a state of utter exhaustion, perfectly unconscious, with his face pale, relaxed, and sweating; pulse undetectable; heart-sounds inaudible; respiration quite arrested. His friends considered that death had actually taken place. Tracheotomy was now rapidly performed, and artificial respiration was resorted to with the result of inducing respiratory efforts, and some return of the heart's action and of consciousness. The hopes thus raised of temporary relief being afforded were not, however, to be realised, as death ensued in about ten minutes from asthenia. The necropsy showed some chronic thickening about the cartilages of the larynx, and a diseased state of the aorta, and, at the termination of the transverse portion and the descending portion, an aneurism of the size of a goose's egg. The recurrent laryngeal nerve was in close contact with, and firmly adherent to, the tumour, and appeared to be somewhat hypertrophied. In this case death appeared finally to result from the exhaustion produced by the repeated attacks of laryngeal spasm, caused by the pressure of the aneurism on the recurrent laryngeal nerve. Death from asphyxia was obviated by the admission of air by an artificial opening; and the partial success of the operation would give encouragement for its earlier performance in any future case. The opinion of the Society was, that in a clear case the operation ought not to be deferred after the occurrence of the second attack of any violent spasm. One case occurred at the Winchester Hospital, in which the operation was resorted to with temporary relief.

*Apoplexy.*—Dr. Wells presented the left hemisphere of the brain of a woman, aged 57, who was admitted into the hospital unconscious and with paralysis of the right side. She lived forty-two hours after admission. The left ventricle was found distended and broken up by effused blood. An interesting point in the history of the case was, that two of her brothers had also died of sanguineous apoplexy.

*Perforation of the Stomach.*—Dr. Wells also read notes of a case of perforation of the stomach in a female, aged 59, whom he saw but once, and whose death occurred suddenly. An aperture of the size of a fourpenny piece was found in the upper curvature of the stomach near the cardiac end. Close upon its margin lay a lump of thickened tissue of the size of a pigeon's egg, apparently cancerous. The points of interest he stated to be as follows. First, although it was evident at the time of his visit that the patient was suffering from severe peritonitis, there was no indication that perforation existed. She was lying on her left side without any appearance of collapse, the pulse not being above 100. Death was sudden and unexpected. He supposed that the aperture had been closed by contiguous parts; and that, on its suddenly opening, the discharge of the contents into the cavity of the peritoneum occasioned a sudden shock to the system, in which she rapidly sank. Secondly, he noticed the relationship of the perforation to the mass of indurated tissue contiguous to it. The aperture did not look like the usual ulcerated opening from cancerous disease, but more like the smooth bevelled perforation which occurs from defective nutrition in chlorotic females.

*Osseous Developments.*—Mr. Harrison read an elaborate paper on some osseous developments. The first part had reference to hydrocephalus and rickets, both of which, he maintained, contrary to the opinion of some authorities, might be congenital. He gave many points of distinction between the two diseases, and considered that the effusion of fluid into the cranial cavity in rickets resulted “not from any inordinate power of secretion, but from diminished resistance of the cranial parietes” due to the absorption, as quickly as formed, of the osseous tissue allowing dilatation, whereas in chronic hydrocephalus the distension depended upon compulsory dilatation, the parietes being normal. He gave the history of one case of congenital rickets which he had treated with suitable diet and a long course of phosphate of iron; marked improvement had already resulted, and he expressed great faith in the treatment, from which he hoped for ultimate restoration. Notwithstanding one distinguishing mark of hydrocephalus, which Mr. Harrison laid down, viz., “its tendency to get worse under any treatment”, there seemed in the discussion which followed to be a strong opinion that the employment of iodide of potassium in what might, considering the tender age of the patients, be called heroic doses was likely, in some cases at least, to be productive of great benefit.—Another case of Mr. Harrison's, illustrated by photographs, which he exhibited by means of the cosmoscope, was that of a girl who, at the age of 11 years, began to have a swelling about the anterior third of the lower jaw on the right side, which in a few weeks increased to such a size as to produce great deformity. A London surgeon of eminence recommended its removal as an exostosis. A dentist advised

delay. The latter course was adopted; and, as Mr. Harrison had ventured to predict, the rest of the jaw "grew up" to this "anticipatory development", and, at the age of 16, the swelling was scarcely noticeable. Although the result was thus good, Mr. Harrison considered that the proper procedure would have been to extract an offending carious tooth, and scoop out the dental cavity, so removing the exciting cause of the excessive deposit.

*Colloid Cancer of the Spleen.*—Mr. Maurice exhibited a specimen from a case of colloid cancer of the spleen, involving also the peritoneum, in a man, aged 36. It was remarkable for the large size and extent of the disease which existed without sooner fatally interfering with functions necessary to life. The mother and aunt of this patient had previously died of mammary cancer.

*II. SURGICAL CASES.—Scirrhus Breast.*—Mr. Maurice showed a remarkably large breast, which he had removed from a female, aged 40, for scirrhus disease. The question of operating was much debated, and the operation was at last undertaken with the hope that the patient's life might be prolonged, and the prospect afforded her of a more easy death than was probable were the disease left to take its course. The tumour, at the time of operating, was rapidly increasing and threatened speedily to involve the skin in ulceration; the axillary glands, too, were somewhat implicated. Whether either object of the operation was attained, is at least doubtful; for although, when the paper was read, the patient was reported to have made rapid progress, to be very nearly well, and able to get about the house, before the wound had entirely healed the disease returned in it, and the patient speedily succumbed, and died within five months of the operation. Such cases are painful reminders of the shortcomings of the surgeon's art, and lead us to look anxiously, though scarcely even yet hopefully, for some means, other than surgical, whereby we may more successfully grapple with this hitherto unconquered foe.

*Fungus Hematodes.*—Mr. Maurice described a case of fungus hæmatodes, for which he had performed amputation just above the knee. H. T. R., aged 54, but looking older, was admitted into the Royal Berkshire Hospital on Nov. 19th. He had a large inflamed swelling over the lower third of the left leg; on the anterior surface a small slough was protruding, about the size of a filbert. He stated that about two years ago he began to find pain in his leg at the seat of an old fracture (which occurred thirty years previously). Twelve months ago it began to swell; but nine weeks since the swelling became more persistent and was afterwards lanced, but there was not much discharge. After admission, another incision was made at the most prominent part of the swelling, and about two drachms of matter were evacuated. The lower end of the fibula was found to be diseased. Soon afterwards large unhealthy fungoid granulations appeared, which bled freely. These continued to increase in size, and the lymphatics of the leg became somewhat inflamed. On the 8th of December the limb was amputated just above the knee. The patient made a somewhat tedious recovery towards a tolerable state of health, and was discharged from the hospital. His recovery was never complete, and he died within a few months at a distance from Reading. The cause of his death was unknown. His life was probably prolonged and his death rendered more easy by relieving him of what, had its progress been unarrested, must have been a foul and unendurable incumbrance.

*Excision of the Knee.*—Mr. Moxhay reported a most interesting series of eight cases of excision of the knee, which he had performed in the Royal Berkshire Hospital. These have been published in the *Medico-Chirurgical Transactions*, and show the excellent result of seven recoveries, but one amputation (and that in a patient whose age and constitution rendered the operation almost a forlorn hope), and no deaths. These cases may surely tend to help the operation in winning its way to the entire acceptance of medical men, a result which, the author of the paper thought, had yet to come to pass.

*Excision of the Hip.*—Mr. Moxhay read an interesting paper on a case of resection of the hip, which he had performed on one of his hospital patients, a lad aged 16. The disease of the joint came on very insidiously either during an attack of fever, or during the convalescence, whilst he suffered from a troublesome bed sore, for which last he was admitted into the hospital on November 2nd, 1869. In October, 1870, Mr. Moxhay removed the portions of bone exhibited, consisting of the greater part of the articular surface of the head of the femur, which was found lying loose in the healthy acetabulum, and the neck and part of the great trochanter. The bone was completely carious in much of its extent, and was found resting on a roughened surface of the dorsum ilii. In January, 1871, union had taken place so firmly as to allow his being pushed up in bed by pressure on his heel. A note in May states that the wound was soundly healed, that he could flex, extend, and rotate the limb inwards, and to a slight extent outwards, and that he was able to bear the weight of the body on the toes.

In Mr. Moxhay's remarks, referring to the union which had taken place, he says, "It is evidently not bony, and yet it is very strong. It is at the same time somewhat yielding, for he can move the limb very freely by voluntary effort. Of course it must be ligamentous union, and we can only thank the beneficence of nature for providing such a means of repair where firmness and mobility are so much required. It is only surpassed by the original construction of the natural joint. This union is wonderfully different from what takes place after excision of the knee-joint. There you have the firm knitting together of the bones, which renders the limb more liable to fracture either at the femur above, or the tibia below the seat of union."

Mr. Moxhay considers that the great difficulty in deciding on the advisability of operative interference in these cases, lies in the fact "that one cannot know beforehand how much disease there may be in the acetabulum and neighbouring bone"; and that, the disease being generally caries and not necrosis, the difficulty of being certain that you have gouged away the whole of the diseased bone, is a real one. One valuable means, however, of getting rid of the first named difficulty, lies in making an exploring cut and using the finger as a probe to ascertain the extent of the disease.

Whilst on the subject of hip-joint disease, I cannot refrain from noticing the method of treatment now being brought before the profession in England by Dr. Sayre, which promises to revolutionise the practice followed in this too common ailment. By a comparatively simple instrument he renders practicable what has heretofore been an unfulfilled desideratum; viz., the application of a sufficient amount of extension to the femur to prevent the painful and injurious contact of its head with the acetabulum, at the same time allowing the patient to make use of the limb for the purpose of taking exercise. Whether the disease be looked upon as one generally of local or of constitutional origin, there can be no doubt that the prolonged confinement required in the carrying out of the important indication referred to by the usual means of splints applied to the limb or of weights attached to it, has a tendency to protract the case.

*Median Lithotomy.*—Mr. G. May brought forward two cases of calculus, in which he had performed the operation of lithotomy according to Allarton's method. The first patient was a man aged 68, who presented decided evidence of kidney-disease, but on whom, in consequence of the severity of the symptoms produced, Mr. May ventured to operate. The stone was a large one of phosphate of lime, with a lithic acid nucleus, and much difficulty was experienced in its removal. Although at first promising well, the case terminated fatally from collapse on the third day. The other patient was a youth of 19. A small oxalate of lime calculus was readily removed on September 2nd, 1870. On the third day all the urine passed *per urethram*, and the patient appeared to be recovering rapidly; but on the seventh the wound reopened, apparently in consequence of the urethra being obstructed by tenacious mucus. It continued open for a week, and then gradually closed, and he was discharged cured three weeks after the operation. In Mr. May's remarks he characterised the operation selected in these cases as one unequalled for facility of execution and for the safety and success of the results. He further remarked that it is not, however, a brilliant operation; for, to ensure success, it is important that the prostate be slowly and gently dilated, or incontinence of urine may result. A method which he thought it would have been better to have followed in the first case is one recommended by M. Dolbeau, to dilate the prostate slowly by a six-bladed dilator, and if the stone exceed an acorn in size to crush it by the lithotrite. This operation has been followed by greater success than any yet known.

Mr. Maurice referred to a case in which he had performed the lateral operation. He acknowledged its greater difficulty, but quoted a high authority for the opinion that incontinence of urine was a much too frequent consequence of Allarton's operation. I find, however, that Dr. Little of New York, as the result of forty cases of median lithotomy lately published, gives, amongst other advantages, that the patient retains control over the bladder.

[To be continued.]

**TESTIMONIAL TO ROBERT ROBERTS, ESQ.**—On the 7th instant, a public meeting was held in the Assembly Room, Blaenau, Festiniog, for the purpose of presenting Mr. Roberts, Surgeon to Oakley's Hospital and Festiniog Slate Quarries, with a testimonial, as a token of the regard in which he is held by the inhabitants, and in appreciation of his valuable services rendered as a medical practitioner. The testimonial consisted of a purse containing £220, together with an address, and a book, elegantly bound, containing the names of the subscribers from half-a-crown upwards.

ON THE PREVALENCE AND DISTRIBUTION OF  
FEVER IN DUBLIN.\*

By THOMAS WRIGLEY GRIMSHAW, M.D. Dub.,

Fellow and Censor of the King and Queen's College of Physicians; Physician to the  
Cork Street Fever Hospital; Physician to and Lecturer on Materia  
Medica in Dr. Steevens's Hospital; etc.

IN bringing forward the following remarks at the present time, I am performing an unpleasant duty; unpleasant, because I have to show not only that fever is more prevalent in Dublin than it had been during the past few years, and that it is on the increase, but that the form of fever considered by sanitarians as the most preventable is the one most increased; that fever is widely spread through Dublin; and that the conditions which favour the spread and production of fever, and with it all forms of zymotic disease, are so rife in our city, that we cannot expect any permanent diminution in fever without some great change in our present sanitary system. It has been my intention for some time to arrange and map out certain information which I have been collecting with regard to the distribution of fever in Dublin, with especial reference to those cases admitted into Cork Street Fever Hospital. I did not intend to make these observations public until after the close of the hospital year in March next; but certain circumstances have recently occurred which have induced me to hurry on these observations, and to add to them some remarks on the prevalence of fever in Dublin.

I do not wish again to refer to the discussion which took place during the autumn, in the Dublin papers and in the *BRITISH MEDICAL JOURNAL*, and in which I took a prominent part; yet I think I may state that, although it may have been attended with some disadvantage to all engaged in the discussion, the public are likely to derive some advantage therefrom, and have been incited to take an interest in the prevention of contagious disease. This occurrence of the discussion to which I have referred caused me to bring forward this paper at the present time. I do not purpose to enter upon the general question of the sanitary condition of Dublin, as I understand that within a short period that question will be fully brought forward by a gentleman who is fully investigating the subject. This paper will naturally divide itself into two parts—the prevalence of fever, and its distribution.

I shall first consider the question of the prevalence of fever in Dublin. I have prepared a table showing the fluctuations in fever and zymotic disease in Dublin during the fifteen years ending March 31st of the current year. This table includes some other diseases not of the febrile zymotic class; but practically these make but little difference in the fluctuations. Fever is practically one zymotic disease; and all the illustrations to the cases in the diagram may be considered as due to the increase or decrease of that disease. The numbers for the years 1857 to 1869 inclusive are derived from the returns to the Dublin Hospitals Board, as published in the reports of that body. The numbers for the last two years are from returns kindly made out for me by Mr. Wilson Hughes, the Secretary to the Hospitals of the House of Industry, and Mr. Eustace, the Registrar of Cork Street Hospital. I have calculated the average from the figures found in the report of the Hospitals Board only, as these are public documents, and can be consulted by any one interested in the matter.

It is thus shown that, commencing with the year 1857, when the Board of Superintendence furnished their first report, fever fell until the year 1859, when it rose again for one year (1860); it then fell again for one year (1861), to rise again continuously until 1866, when the number of admissions reached 3,562. In this year cholera also prevailed; and as that disease is included in the Hardwicke Hospital returns to the number of 187, this number may fairly be taken off the total, leaving the number 3,375, almost the same as the preceding year. Cholera cases are not admitted into Cork Street Hospital. Fever prevailed to a greater extent during the year 1866 than at any other time during the period under consideration. The numbers in Cork Street Hospital on one day reached 185, these being nearly all typhus cases. From 1866 (year ending March 31st, 1867) fever steadily decreased, until the year 1869, when the admissions reached but 1,821. It has, however, been since rising; the admissions having been 2,264 and 2,345 respectively for the two years ending March 31st, 1871. It will thus be seen that the rate of admission to the fever-hospitals was much the same during the year ending March 31st, 1871, as it was ten years ago. The rate of admissions into Cork Street Hospital, I find, corresponds with the rate of the total admissions into the two hospitals; the only exception being in the year 1864. The admissions into the Hardwicke Hospital do not so closely correspond with the total admissions. I

believe that the close correspondence between the admissions into Cork Street Hospital and the total admissions depends on the fact that the accommodation in Cork Street is practically unlimited, as for only one day during the fifteen years under consideration was it necessary to give notice that no more patients could be received, and fortunately this notice had not to be acted upon. Another reason is that, as far as practicable, none but contagious febrile diseases are admitted into Cork Street Hospital. The close proximity of the hospital to the worst fever-districts is an additional reason why the admission-rate should so closely measure the prevalence of fever. From this account we see that fever, which had decreased, has been on the increase for the past two years.

We may test this question, again, in another way, but not for so long a period, by consideration of the death-returns of the Registrar-General, as published in the weekly slips for Dublin. I have arranged the number of admissions into Cork Street Hospital by quarters, for the five years ending September 30th, 1871, and the deaths from fever registered during the same period. I have for each year divided the number of admissions by the number of deaths; and though the result is always the same, the correspondence appears to me to be surprisingly close. If we compare the annual death-rates with one another, we find that for the past two years fever, and deaths from fever, have increased to nearly what they were five years ago; and both are above the average of the five years under consideration.

I have thus shown that fever has not been permanently checked in Dublin, but is in nearly the same state as it was ten years ago, and is above the average of the last five years. I believe that the low fever-rate of the years 1868 and 1869 was but one of those temporary fluctuations which occur from time to time, and that it cannot be ascribed to action taken under the Sanitary Act of 1866; or if it can be ascribed to such action, then the measures taken must have been so relaxed that fever is resuming its old sway in Dublin.

I have next to consider the relative prevalence of late of the different forms of fever. In considering this question, we may leave relapsing fever out of the question, as but two cases of that disease have been admitted into Cork Street Hospital during the past two years. From the tables and diagrams which I have constructed and here show, it will appear that, while typhus and simple fever have been on the decrease, enteric fever has been on the increase. Thus, in the year ending September 30th, 1870, typhus was above the average during eight months, while the following year it was above the average for but four months. On the contrary, enteric fever was but one month above the average in the first year, while in the second it was above the average for nine months. It is worth remark here, that the increase of the simple forms of fever generally accompanies, or immediately precedes or follows, increase in some one of the other forms. When it is remembered that enteric fever is generally considered by sanitarians to be dependent on bad drainage or impure water-supply, it is difficult to account for the sudden increase of that form of fever in Dublin, as we show that the water-supply is nearly perfect, and that the drainage has been steadily, though slowly improving. It has been suggested to me that the stirring up of dirt, consequent on the construction of new drains, might be the cause; but I cannot see that this can account for it, as I find fever connected with local unsanitary conditions, and I have not, in any of the fever-nests which I have visited, discovered that there has been any such stirring up, for the very good reason that there has been no attempt at forming effectual drains for these houses. I do not believe that the Vartry water is the cause; as, if it were, the increase of enteric fever should have occurred before the present year. I admit, however, that I have heard of a suspicion of sewage-pollution of the Roundwood reservoir. There is one way in which the Vartry water may have indirectly caused pollution of drinking-water; namely, people not liking the Vartry have taken to an old pump; and I have given a considerable number of instances of this kind. I think, however, we must look to the peculiarity of the weather which we have lately had, especially its dampness, as a cause. But here I am again puzzled, as I have found that an increase of moisture favours an increase of typhus, and showed this to be the case in a paper read before this Society on January 17th, 1866; but this will not explain the production of enteric fever under similar circumstances. I believe myself that the conditions favourable to the production and spread of typhus and enteric fevers are more closely allied than is generally supposed to be the case. I shall presently show that all forms of continued fever are frequently produced under identical circumstances.

I must now proceed to the second part of my subject; namely, the distribution of fever in Dublin. If we look to the distribution of fever in Dublin, as shown by the death-returns of the Registrar-General for the five years ending September 30th, 1871, it will be seen that of the 1,476 deaths from fever during that period, 922 were on the south side of the city, and but 554 on the north side. This is not merely owing

\* Read before the Medical Association of the College of Physicians, November 15th, 1871.

to the larger population of the south side than of the north; for the ratio of deaths to population on the south side of the city was 1 in 149.8, while it was but 1 in 177.5 on the north side; the annual average being 1 in 977.3 for the north, and 1 in 746.1 for the south side. This state of things is easily accounted for when we compare the population per acre on the north and south sides: it being but 57.9 per acre on the north, while it is 70.8 per acre on the south side; and this gives but a faint idea of the density of the population in the fever-districts. Thus, in Woodquay Ward, which includes a considerable portion of the worst fever-district, the population is 145 per acre, which we may compare with Fitzwilliam Ward, part of which nearly touches on the fever-district, where the population is but 52 per acre. It thus appears that the great bulk of the fever of Dublin occurs on the south side of the city. To this side I shall confine the rest of my remarks with regard to the details of the distribution of fever, and the localities whence the Cork Street Hospital patients are derived. This portion of the inquiry will consist of three parts: (1) the districts where fever prevails; (2) the streets which furnish the largest number of patients; and (3) the homes of the patients. With a view of making the inquiry as complete as possible, I have taken into consideration the streets which have furnished fever-cases during the past ten years; but, as it would be of little practical utility to know the exact locality where fever prevailed several years ago, I have only gone minutely into the inquiry for the two years ending September 30th, 1871. This inquiry embraces the south side of the city only, which I may call the Cork Street Hospital fever-field; while the north side may be called the Hardwicke Hospital fever-field. Some cases of fever pass from the south side to the Hardwicke Hospital; and some—perhaps a greater number—come from the north side to the Cork Street Hospital; but practically, Cork Street gets all from the south, and Hardwicke all from the north side. The same allowance has also to be made for the cases admitted into Steevens's, the Meath, Sir P. Dun's, the Adelaide, and City of Dublin Hospitals. These act as disturbing causes, especially each in its own locality, and, of course, impair the accuracy of some of the results as marked on the map; but they will not, I think, affect materially my conclusions as to the distribution of fever on the south side of the city. This inquiry extends over two years, and embraces investigation into the circumstances connected with 1,825 cases of fever (including only simple, typhus, and enteric fevers) derived from 1,190 houses, and from 266 streets, lanes, courts, and alleys. Although an inquiry into the distribution of scarlatina, small-pox, and other forms of contagious febrile diseases would be of great interest, yet, as these diseases are less within the control of sanitary measures than the continued fevers (small-pox excepted), and as it would tend to complicate the present inquiry, I have excluded these from consideration in this paper, and confined my attention to the continued fevers only.

On looking at the marked portions of the map on which I have marked the fever-houses with red dots, any one well acquainted with the south side of the City of Dublin will at once see that the fever-streets are naturally distributed among three districts, and these districts are not only naturally divided by the lie of the city, but also by the nature and age of the streets and houses contained therein, and, what is more important for our present purpose, by the prevalence of fever in each.

The south side of the city may be divided into four districts by two lines of streets. Of these, three are fever-districts—the north-east, north-west, and south-west. The fourth—the south-east—may be said to be free from fever, except a small portion south of Lower Mount Street, which might fairly be included in the north-east division. For my present purpose, I shall name three districts as follows: 1. Coombe Valley (south-west division); 2. West River (south-east division); 3. East River (north-east division). I have numbered these in accordance with the prevalence of fever in each, the first furnishing by far the largest number of cases. Each of these districts has some outlying districts, to which I may have to refer again. Besides these, there are certain places outside the south city, from which a considerable number of cases are derived. There are also several public institutions which send cases to Cork Street Hospital. The East River district is lower lying, and, therefore, less easily drained than the West River, but has the advantage of being more open to sea-breezes and fewer nuisances; for, although the vitriol works are objected to by some, yet I think these must be considered as rather wholesome than injurious, as they are constantly effusing disinfectants through the neighbouring atmosphere. So much for the districts. I shall next consider the distribution of fever through these districts. I have divided the houses furnishing fever-cases into three classes; namely, 1. Those furnishing five or more cases during the two years ending September 30th, 1871; 2. Those furnishing three or four cases; 3. Those furnishing one or two cases only.

From the table I now show, it appears that the bulk of the fever-

cases are furnished from the Coombe Valley district. While the average proportion of fever-cases to each fever-house is nearly the same in each district, the proportion of fever-houses per street is much greater in the Coombe Valley than in the other districts, being 5 per street against 3 and 2½ in the West and East River districts respectively, showing that the fever-houses are more closely set together in the former than in the two latter districts. The proportion of bad fever-nests to fever-houses generally is less in the Coombe Valley than in the West River district, and about equal to that in the East River; and this is also true of houses furnishing three or four cases: thus showing that the cases are more concentrated in individual houses in the two latter than in the former district. In fact, fever is more equably and closely distributed over the Coombe Valley than the other districts.

We have now to consider the streets, lanes, alleys, and courts whence the fever-cases come. The streets are generally characterised by being composed of old—many of them once fashionable—houses, with bad rear accommodation, or no back yards at all. It is not essential, as many suppose, that fever-streets should be narrow and tortuous; on the contrary, two of the worst fever-streets—Meath Street, the very worst, and Francis Street—are wide and straight. It is the age and condition of the houses, and proximity of narrow courts and alleys that especially characterise these streets, together with the want of proper house-drainage, ash-pit, and privy accommodation in the houses themselves. As examples of the worst fever-streets, I may mention Meath Street, with its 95 houses, 36 or more than a third of which furnished in all 73 cases of fever to Cork Street Hospital during the two years. It contains one fever-nest furnishing six cases, and ten others furnishing three or four cases each. Francis Street, with 140 houses, has 28 fever-houses furnishing 55 cases; there are in it two fever-nests furnishing more than five cases, and a house furnishing three or four cases each. The Coombe contains 129 houses, and has 46 fever-houses furnishing 78 cases, one house furnishing five cases, and four others furnishing three or four cases each. These are sufficient detailed examples of fever-streets, but I could mention many others nearly, though not quite, as bad. The lanes and alleys are probably more than the streets, but must be merely looked upon as streets on a smaller scale. The courts (comprising yards and squares) are most to be considered. These are perhaps the most prolific fever-beds, as few of them have failed to produce fever-cases during the past two years. Fever-streets are generally skirted by these courts, notably those which I have already given as special examples of fever-streets. There are several kinds of courts: (1) those originally constructed as such; (2) those closed up at one or both ends; and (3) back yards and gardens that have, by the cupidity of the owners, been built upon, the out-offices being converted into dwelling-houses, thus crowding together a large number of small tenements in a very comprised space. These latter are generally known by the name of yards, or are only designated by the number of the house behind which they are situated. Few people, besides clergymen and medical men, are acquainted with the existence of these places.

Examples of the first form of court may be found in abundance off South Great George's Street and King Street, and a considerable number in the neighbourhood of Townsend Street. They are, in fact, narrow blind lanes, and have usually an open sewer running down the centre through the whole length, and emptying itself into the adjoining street, or into a trap near the entrance to the court. These traps are frequently choked, and large quantities of sewage accumulate. There is usually a privy, seldom more than one, situated in each of these; as also in the other form of courts, the drainage from this privy of course finds its way down the open sewer already described in the centre of the court. The square may be considered as the best of these forms of court examples, of which are Gell's Square, off Cole Alley; Neil's Court, off Marrowbone Lane; Duby Square, off Nicholas Street, etc. These squares have usually no drainage, and are surrounded by miserable, old, overcrowded houses, and are generally strewn over with rubbish and filth, consisting to a great extent of human ordure, and have one or two cesspools near the centre. I have already indicated the nature of the yards, several of which may be found in Marrowbone Lane, Cork Street, and the Coombe. The houses in all of these are of the most filthy character, and the front house or houses to the street generally indicate the nature of what is behind, having the usual character of a fever-nest, to which I shall presently refer more particularly. The ground of all these courts is saturated with decomposing organic matter, chiefly human excrement.

I have already pointed out that the houses from which fever-cases have been derived number 1,190, with a few more added since my list was made out; in round numbers, 1,200 of these houses furnished 1,825 cases, with some additional ones not included in the classified list, making in all, in round numbers, 2,000 cases. Of these infected houses,

41 furnished five or more cases each; the nature of the cases furnished by each are put in Table 6; again, 81 houses furnished three or four cases, which are particularised in Table 7; the remainder of the houses furnished but one or two cases each.

The analysis of these tables give the following result :—

53 houses furnished	3 cases each.
28 " "	4 " "
16 " "	5 " "
12 " "	6 " "
2 " "	7 " "
3 " "	8 " "
1 " "	9 " "
2 " "	10 " "
2 " "	11 " "
1 " "	17 " "
2 " "	doubtful.

122

The total number of cases furnished by these 122 houses was 534, or more than a fourth of the whole number, showing how prolific these fever-nests are, and how much they endanger the health of the community, which is particularly suggested by 48 of these houses having fever-houses next door to them. The kind of fever furnished by these houses is an interesting point. Of the houses furnishing five or more cases—

13 houses furnished	cases of three kinds of fever.
19 " "	simple and typhus.
4 " "	enteric and simple fever.
4 " "	typhus and enteric.
2 " "	simple only.
0 " "	typhus only.
0 " "	enteric only.

This shows that the most infected houses, as a rule, furnish more than one form of continued fever, proving that any one case of fever occurring in a house should at once direct the attention of the sanitary authorities to that house, with a view of arresting its spread, and the probable production of all kinds of fever. It is far from improbable that many of these houses which have furnished but one or two cases of fever are just commencing their career as fever-nests. I may mention that several of these fever-nests have also produced small-pox, scarlatina, measles, and cholera; of the last, I may mention the notorious house, 22, City Quay, where cholera first made its appearance in 1866.

What are the characters of a "fever-nest"? The best way to answer this question is by describing one or two. I shall begin with the worst on my list, 58, Bridgefoot Street, now celebrated as a fever-nest, defying the sanitary authorities. This house is entered from the street by a passage with a black and rotten floor, in which are open chinks communicating with the cellar below; the boards are damp and sodden with dirt; going upwards, we find things somewhat better, but the whole upper part of the house is dilapidated; going downwards, we first come to the entrance to a small back yard, a place covered ankle-deep with human filth, a privy and ash-pit totally unapproachable without passing through a sea of dirt, a water-tap running and washing such of the dirt as is within reach into a pipe-sewer which runs through the cellar of the house, and which has a hole in it, through which the sewage passes into the cellar, converting it into a cesspool. This cellar was immediately beneath two rooms inhabited by a family of fifteen, every one of whom had enteric fever. In the same street I found another house with all these characters repeated, except the broken sewer, but this house had no sewer at all—a house in Chancery Lane, which furnished eight cases of fever (seven of typhus and one enteric). I was met on entry by a horrible stink, proceeding partly from a filthy back yard, and partly from slaughter-house at the rear of a neighbouring house in Bride Street. The cellar of this house had been filled up, a very proper measure if rightly carried out, but the filling-up material consisted of such material as to fill the cellar with a decomposing manure-heap. The passage, back yard, and upper part of the house were similar to those already described at 58, Bridgefoot Street. I find similar conditions, varying, only in degree, in almost every fever-nest. The less prolific fever-nests I find with less accumulated dirt, and notably less wet dirt. In many places where there was comparatively little dirt, what did exist was made to do the maximum amount of damage by being kept in a continued state of moisture, for want of proper drainage, or from drainage-water from the roof or elsewhere running into the house by the doors, or through imperfectly or not at all closed cellar-openings. These damp cellars, often nearly filled with rubbish, are to be found in all fever-streets and most fever-houses. Many houses have no receptacle for rubbish except the cellars; this is particularly true of corner houses

and houses near corners, many of which, if not public-houses, are fever-nests.

We have next to consider the remedies for this state of things; these may be easily summed up in three words—cleansing, draining, and clearing. I believe the only cure for many of these places is a complete clearance of the ground. I consider that all closed courts should be abolished, either by an opening up to the main street, or by complete demolition of the houses themselves. Perfect house-drainage should be insisted on; all cellars should be filled up with dry mineral materials; all privies and ash-pits should be cleansed by the authorities—not left to be done by the owners, who will not, or the occupiers, who cannot do it. The person receiving the rent from the occupier should be made responsible for the proper sanitary conditions of the house; no excuse should be taken about the existence of another landlord. All tenement-houses should be regularly inspected, not by policemen, whose fellow-policemen often own or farm these houses, or collect the rents, but by proper and well qualified health-officers, and no better could be found than the dispensary medical officers. Houses where fever has once occurred, should be constantly watched and reported upon. Street-lists of infected houses should be kept, such as I made when I undertook this inquiry.

Three preventive measures seem to me to have been altogether neglected. In Dublin, no proper sanitary organisation seems to exist; there is but one health-officer, and he is badly paid; the sanitary inspectors are policemen, who go to inspect the houses of their friends; and the reports of infected houses by the hospitals and dispensary medical officers are systematically ignored until they are sent to the newspapers; but as these are matters of public notoriety, which have now gone for months without any public contradiction, I shall not further refer to them, but appeal to my professional brethren to use their influence with the public to compel the authorities to do their duty, and prevent the spread of contagious diseases in our city.

## ON A REGULATED TEMPERATURE IN THE TREATMENT OF DISEASE, ETC.

By ALEXANDER ROBERTSON, M.D.,

Physician to the Town's Hospital and City Parochial Asylum, Glasgow.

AMID all the changes in medical opinion regarding the therapeutic value of the agents with which we seek to conquer disease, none have sustained their time-honoured reputation so well as heat and cold. Without exaggeration, it may be said that, in one or other of the modes in which they are employed, they are of universal application, and that their power in alleviating pain and in promoting the restoration of health is acknowledged by all. We appear, however, to be only now beginning to form a proper estimate of their exceeding importance as remedial agents in certain forms and stages of disease. In illustration of this remark, I need only refer to the observations which have been recently made on the reduction of hyperpyrexia in febrile conditions of the system, due to various causes, by means of the cold bath. In this direction, a wide field seems to be opened up, which promises richly to repay the labours of many explorers.

In the beginning of this year (February), when considering the different classes of remedies employed by medical men in the exercise of their vocation, I was forcibly struck by the fact that these agents, heat and cold, as they are used through the medium of poultices, fomentations, and cooling lotions of various kinds, are not, as a rule, prescribed with any attempt at precision. To take the case of the poultice: it is clear that its temperature often differs widely, according to the skill and care exercised by the nurse in its preparation. It is also equally evident that, though applied as warm as the patient can bear it, before long it parts with its excess of heat. But, so far as I have been able to ascertain, no exact observations have hitherto been made to determine the length of time during which it retains a temperature higher than that of the part with which it has been in contact, and how soon a renewal of the application is required. No certain indication can be gathered from the practice of medical men in treating similar conditions of disease; for some order fresh poultices every hour or two hours, while others are contented with having them changed three times a day.

Similar observations may be made with equal propriety regarding fomentations. However, they are usually changed more frequently than poultices; though, upon the whole, there is not much greater uniformity in practice.

Considering these facts, it occurred to me that in many instances it might be an advantage to maintain these agents at or near the degree of heat which was originally applied; and, further, that various zones of temperature, so to speak, might not improbably yield different therapeutic results; for instance, that ranges from 140 to 145 deg., 115 to 120 deg., 105 to 110 deg., and others down to the freezing point, might each be expected to produce effects somewhat dissimilar to those of the others, either in degree or kind, both locally and constitutionally, when continuously maintained for definite periods. Moreover, though as a minor consideration, where the maintenance of an equable temperature did not seem necessary or desirable, it promised to be of considerable importance to have it in our power to renew the heat of the original application without uncovering or otherwise disturbing the patient; as it is apparent that much of the advantage obtained by the use of the poultice or fomentation is lost in many cases from the exposure and annoyance to which the sick person is subjected by its renewal at short intervals.

As a preliminary inquiry, I thought it requisite, for reasons which I have already indicated, to institute a series of observations in order to determine how long these agents, the poultice and fomentation, as they are ordinarily employed, retain a heat higher than that of the surface on which they have been resting. I have also made a number of investigations with the view of ascertaining the direct effects of the mustard and mustard-and-linseed poultice on the functions of some of the leading organs in different forms of disease. This subject seemed worthy of special consideration on its own account; but my chief object was to obtain data, as exact as possible, with which I might contrast the results of the application of a regulated temperature, afterwards to be recorded.

Both series of observations, it is proper to remark, were made by myself. I shall first refer to the poultice and fomentation, in relation to the rate of cooling only. Certain general remarks are applicable to the inquiries with both of these agents. Thus, in both cases, the patients selected were all adult males, the great majority of whom were from twenty to forty years of age, the oldest being forty-nine. None were chosen in whom there was any material disturbance of the system. The temperature of each person was taken in the axilla before beginning the observation, and the range was found to be from 97.6 to 99.6 deg.; only two attained the latter degree, the great majority being at or within 0.4 of 98 deg. The subjoined temperatures are to be understood as the average of the results obtained for each group of cases. The Fahrenheit scale was employed throughout all my investigations.

**I. Poultices of Linseed-meal.**—Observations were made in forty-one cases, which are arranged in ten groups. The poultices were applied to the arm and the chest during successively increasing periods; viz., half an hour, an hour, two hours, and four hours. Some of them were covered with vulcanised cloth, others with flannel. I subjoin only one group in illustration of the others. **Group 8.**—Three cases. Poultice to chest for half an hour, covered with vulcanised cloth and under-flannel shirt. Applied at 140 deg., fell to 102.6 deg., next skin; 103 deg. next vulcanised cloth: loss 37 deg. Highest temperature on application, 144 deg.; lowest 135 deg.; highest at close, 105 deg.; lowest, 101 deg. Temperature of room, 62 deg.

Similar investigations were made with fomentation. The number of cases was twenty-two, which were arranged in four groups.

The general conclusions at which we arrive from a consideration of the results of these observations are, with respect to the poultice, the following. 1. However warm it is when applied, in the course of half an hour it will fall to within two or three degrees of the axillary temperature; in exceptional cases, it may be four or five degrees higher than the armpit, but in others it will be a degree or two lower. 2. Its loss of heat afterwards becomes gradually slower, so that at the end of an hour, on an average, it is not lower than the axillary temperature, and in a very few cases may be a degree or two higher. 3. However long it may be applied, its temperature does not fall more than five or six degrees below that of the axilla. 4. A moist poultice retains its heat somewhat longer than a dry one.

With respect to the fomentation, we find that it loses heat more rapidly than the poultice, so that even at the end of half an hour its temperature is lower than that of the axilla; but that, like the poultice, it does not descend more than five or six degrees below that point.

I need scarcely say that, in parting with their heat, these agents are obedient to the laws which regulate the cooling of heated bodies in general; and that the above conclusions might, for the most part, have been anticipated by a consideration of these laws. But though this is doubtless true, it seemed to me, from the great importance of the subject in a practical point of view, that it was desirable to submit them to the test of actual observation.

As a corollary to these conclusions, I remark that, if we consider it

right to maintain a temperature higher than that of the body in the treatment of disease, we ought to change such applications every half hour or hour. No doubt benefit is often derived from them when the heat is not greater than that of the axilla, partly, of course, from the associated moisture. But, though this is admitted, I think it is equally well ascertained that they are more beneficial when hotter than the surface to which they are applied. Even the instincts of our patients tell us so: for it is within the experience of every one that, when either of these agents is considerably warmer than the painful or inflamed part under treatment, a soothing comfortable sensation is experienced.

But, on the other hand, were we to renew the poultice or fomentation as often as the foregoing conclusions indicate to be necessary, the sick would suffer not only discomfort, but positive injury from the exposure and disturbance to which they would be subjected. It must, I think, have been observed by most practitioners, that such results do follow their renewal at short intervals. I hope, however, to show that, by means of apparatus which I have designed, this difficulty may be obviated.

We now turn to the action of the mustard poultice, and mustard-and-linseed poultice, on the functions of the leading organs of the body, both in health and disease, but chiefly in the latter condition.

**Mustard Poultice.**—Five patients, all men, aged from 51 to 64, except one at 22; all suffering from bronchitis, or bronchitis with emphysema, of moderate severity, with one exception, which was severe. Mustard was spread on cotton cloth, covered with muslin, and applied for thirty minutes to the front of the chest. The temperature of the poultices on application was from 76 to 98 deg.; at the close, it varied from 91 to 95 deg.

**Results.**—(a) *Pulse per minute.*—In three cases there was an increase, viz., from 64 to 74, 82 to 88, 120 to 126; in one case it remained the same, 70; in the other one, a decrease of six is recorded, but this man's pulse was irregular. (b) *State of Skin* in regard to perspiration. —In three cases, no change was observed; in two, where slight perspiration existed on the application of the poultice, the surface generally was drier on its removal. (c) *Respiration per minute.*—In two cases, there was no difference; in one, there were was one less, 29 instead of 30; in two others, it had risen respectively from 28 to 31, and 28 to 34. (d) *Temperature of rectum.*—Two continued the same, viz., 98.8 and 100 deg.; in two, there was a reduction in each of 0.2 deg., viz., from 101.2 to 101 deg., and from 99 to 98.8 deg.; in one, there was an increase of 0.8, viz., from 104.4 to 105.2 deg.

Two of the patients considered that they were relieved, to some extent, of pain and oppression in the chest; three did not experience any benefit.

These cases indicate that, when the functions of respiration and circulation are affected by the application of mustard in bronchitis, and probably in other forms of disease also, it is in the direction of increased exercise. It is worthy of note that, in two cases where the heart's action became more rapid, there was a decrease in perspiration.

I would direct special attention to the case in which there was an increase of 0.8 deg. in the temperature. The patient's age was 51. He had been bronchitic for many years. The poultice was applied at 8 P.M. At that time, his condition was as follows: temperature of rectum 104.4 deg.; respiration 28; pulse 120; skin dry: while at the close, the temperature was 105.2 deg.; respiration 31; pulse 126; skin dry. This aggravation of the symptoms may, no doubt, have been caused by the rapid increase of the disease; but it was more probably produced by the poultice, as it occurred within half an hour after its application. The results in this case, and in the group generally, show that the mustard poultice excites some of the leading organs to increased action, especially in the more severe forms of disease, and suggests that the morning or early part of the day is the more suitable time for applying it, so that the evening exacerbation, so common in acute disease, may not thereby be increased.

**Mustard-and-Linseed Poultice.**—Seven cases were observed, six males and one female. The ages ranged from 30 to 64, except one, a boy of 13. They suffered: four from bronchitis, one from phthisis pulmonalis, one from lumbago, and one from spinal disease; and the disease in each was of moderate severity. The proportions of the ingredients were, one of mustard and three of linseed, which were thoroughly mixed. The average temperature of the poultices on application was 135 deg.; maximum, 146 deg.; minimum, 121 deg. The average temperature at the close was 91 deg.; maximum, 95 deg.; minimum, 88 deg. In five instances it was applied for two hours; in two others, respectively for an hour and half an hour. The application was made to the front of the chest in five cases, and to the spine in the two others. I have classified together the five which were continued for two hours.

**Results.**—*Pulse.*—In three, there was a reduction varying from 2 to 20; in the remaining two, there was an increase: in the boy, aged 13, of 22,

and in the woman with spinal disease, of 10 per minute. *Temperature.*—In four cases, it was observed in the rectum. In three of these, there was no change; in one, there was a decrease of 0.8 deg. In the case of spinal disease observed (in the axilla), there was also a decrease of 0.8 deg. *Respiration.*—By an unfortunate omission, the respirations were not counted, except in two cases; in one of these, no change was noted; in the other, there was an increase of four per minute. As to the state of the skin in regard to perspiration, no difference was observed in any of the cases.

In the case where the poultice was continued only for an hour—one of bronchitis—the pulse fell eight, the temperature of the rectum was 0.2 deg. less, and the number of respirations was the same. In the other person, also a sufferer from bronchitis, but of greater severity, the pulse was ten fewer, falling from 128 to 118; the respirations were four more; the temperature of the rectum was 0.4 deg. less. No change was observed in the state of the skin in either patient.

The general results obtained, though not very decided, were in most cases favourable, more so than with the mustard alone. This observation is supported by the decrease both of the pulse and temperature in some of the patients. The boy aged 13 was, however, a marked exception, as his pulse was 22 higher at the close. Struck by this fact, it occurred to me that it would be desirable to contrast it with the effects of a similar application on a thoroughly healthy child. Accordingly, I selected for observation a lively, good tempered boy, aged 10, apparently in excellent health. The following were the conditions: 2.40 P.M., an hour after dinner; temperature of apartment, 64 deg.; in bed, under two pairs of blankets and cotton coverlet; pulse 80, of average strength. The skin in all parts was warm and soft, but not perspiring; temperature of rectum (six minutes), 99.6 deg.; the respirations 23 per minute. A poultice was then prepared, consisting of one tablespoonful of mustard and three of linseed meal thoroughly mixed, spread on cotton cloth to about three-fourths of an inch in thickness, and applied at a temperature of 124 deg. to the front of the chest, muslin intervening between it and the skin. I had intended continuing it, if it could be borne, for two hours, and purposed recording the effects every half hour during that time; but, after thirty-three minutes, he complained so much of pain, that I was under the necessity of removing it. His pulse then was 106, and there was no appreciable change in the state of the skin generally, nor in the temperature, as observed in the rectum. He complained much of pain, and was so restless that the respirations could not be counted till a quarter of an hour after the removal of the poultice, when they were 23 or 24 per minute. Ten minutes after it had been taken off, he felt the surface still hot and sore; but the pulse had fallen to 96. In ten minutes more, the pulse was 80; he was calm, and said that he was almost free from pain.

We see, then, that in a healthy child, the mustard-and-linseed poultice very decidedly excites the heart's action, and also produces considerable pain and mental irritation. From what we know of the still greater susceptibility of the very young, we may consider it nearly certain that these effects would be even more marked in a healthy infant. An excited action of the heart, pain, and mental irritation, can scarcely be regarded otherwise than evils; so that, in applying poultices either partially or entirely composed of mustard to young patients, we have to consider whether the advantage we expect to obtain will more than counterbalance the directly injurious effects of the agent itself; and also if the desired result might not be procured in some other way, either without these accompanying disadvantages, or in a subdued and milder form, if they cannot be avoided altogether.

[To be continued.]

## ON THE TREATMENT OF NOCTURNAL ENURESIS AND SPERMATIC INCONTINENCE.

By D. CAMPBELL BLACK, M.D., L.R.C.S. Edin., Glasgow.

I AM induced, in consequence of the perusal of a paper by Dr. Bradbury of Cambridge on the above subjects (see BRITISH MEDICAL JOURNAL, April 8th, 1871), to make the following brief observations.

While I am perfectly willing in all cases to accept recent additions to our pharmacopœia, and accord to them their due credit, I am painfully sensitive to the inordinate enthusiasm which all such additions evoke; and I am persuaded that, in consequence, old and valuable medicinal agents are too frequently consigned to unmerited desertion. It is a pleasant thing, in the practice of physic, to be able to lay hold of ultimate facts, and my experience in the treatment of the affections under consideration affords one or two, of whose reality I am thoroughly convinced. I make a claim, therefore, for old agents of the pharmacopœia.

The analogy between nocturnal enuresis, spermatic incontinence,

and all other involuntary actions of muscular fibre, and epilepsy, which Dr. Bradbury points out, is to me not novel. A due equilibrium of nervous influence is at all times essential to normal function; and, when undue elevation or depression on either the psychical or the somatic side occurs, normal function, so to speak, becomes unhinged, and functional or organic changes ensue. The machinery—to carry out the analogy—whereby nervous influence is regulated, consists of the sensory or afferent, and the motor or efferent nerves. The sensory nerves, under the influence of stimuli, transmit, probably by molecular action, impressions to the central organ—the brain—through which they are communicated to the motor. In this manner, abnormal peripheral irritation may occasion functional disease; and, thus guided, the cause of the irritation must be ascertained in every given case, and treated as its peculiar exigencies demand. On the other hand, the very converse of this may happen, through the influence of the mind. This being the psychical disturber of nervous balance, its cause must in like manner be determined, and the appropriate remedies enjoined.

That the various secretions of the body, and many of the organic or involuntary muscular movements, are powerfully influenced by mental emotions, is an universally acknowledged fact. Thus strong mental emotions may arrest the secretion of milk; the salivary glands, in cases of urgent thirst, are stimulated to increased secretion by the mere idea of water; the action of the heart is accelerated by anger or other violent passion, or depressed, as in syncope, by fear, etc. This law—that of emotional stimulation, as it may be termed—finds expression in the old aphorism, *Ubi stimulus, ibi humorum uberior affluxus*.

The close relationship of functional aberration of the genito-urinary system with the brain, and consequently their mutual interdependence, is further illustrated in the distribution of the sympathetic nerve. It is peculiarly through this nerve that the conditions enumerated influence secretion. This very important nerve, or rather nervous system—that of common feeling (*cœnæsthesia*, *κοινὸς αἰσθησις*)—is to a great extent independent of the brain and spinal marrow. It has been separated, for purposes of description, into three distinct foci: (a) the focus of generation, (b) the phrenic focus, and (c) the solar plexus. The thoracic portion of the sympathetic is situated on the side of the vertebral column as far as the last two dorsal vertebrae. During its course, its ganglia are twelve in number; and its branches are divided into branches of communication and branches of distribution. At the termination of the pneumogastric is situated the solar plexus. From this centre, accompanying the branches of the aorta as “governors”—to carry our analogy still further—of secretion, the sympathetic distributes branches. In addition, therefore, to the diaphragmatic, gastric, hepatic, splenic, suprarenal, renal, mesenteric, and aortic, we have spermatic plexuses. Besides these branches, the pelvic organs derive branches from the lumbar and sacral portions of the parent trunk: hence there are described the hæmorrhoidal, vesical, prostatic, vaginal, and ovarian plexuses. Our position, therefore, is this—that functional diseases of glands, organic muscular fibre, etc., may be either of psychical or somatic origin, *i. e.*, due either to peripheral or to central irritation; and that, accordingly, their rational treatment resolves itself into psychical and somatic appliances. I am thus a firm believer in the ancient creed which associates hysteria with some disturbance of ovarian, vaginal, or uterine cœnæsthesia; the abundant secretion of urine which accompanies this disorder clearly demonstrates the influence of the sympathetic over this secretion; while, in respect of treatment, the efficacy of some powerful mental emotion of a counteracting nature is very manifest. Thus the cold-douche treatment, which is so successful, finds explanation, doubtless, in a feeling of indignation having overcome a different mental impression; and so on. A familiar illustration of the same influence occurs in the curing of hiccup by the creation in the mind of the patient of some powerful emotion, by being charged with the commission of some derogatory act, etc.

With respect to enuresis, the disturbing influence I believe to be generally of a somatic nature; while, in the case of its prototype, spermatic incontinence, it may be either psychical or somatic, either of them, or both. Enuresis generally occurs at the periods of infancy and declining years; and, according as it may so occur, its cause admits of different explanations. In childhood, it is almost invariably traceable to the irritation of worms, congenital phimosis, calculi, or perverted secondary assimilation causing urinary density and acidity. These causes being removed, the sphincter muscle recovers its tone, and a cure is effected. But, if the hyperæsthesia have been long continued, a debility of muscular fibre ensues, and a tonic treatment is indicated in addition. In advanced life, the conditions mentioned are generally absent; and the cause of the enuresis is found in enlarged prostate, a general enfeeblement of muscular structure, and affections of the spinal cord, or calculi. Such being the pathology of this affection, I have invariably treated it with narcotics and tonics, or rather a particular

tonic; and I claim for camphor, opium, belladonna or hyoscyamus, with the tincture of the muriate of iron, properties, I am satisfied, inferior in their influence over the bladder to no preparations in the pharmacopœia. But it is indispensable, according to my experience, that the tincture of steel be given much in excess of the usual dose. Of this, however, more in the sequel.

With respect to spermatic incontinence—an infirmity which has been made so much stock of by quacks both in and out of the profession—my experience of the use of the agents mentioned has been equally satisfactory. Into the consideration of the psychical origin of this infirmity, I do not at present enter. It may vary in intensity from a slight impression to erotomania; and it is an admitted fact that enfeebled health may be traceable alone to an intense occupation of the brain by lascivious ideas. On the other hand—the somatic side—local irritation (how caused, I do not stop to consider) is, in my experience, seldom or never absent. When consulted regarding such cases—a numerous class in city practice, and requiring the tenderest consideration on the part of the practitioner—my invariable custom is to pass a catheter or bougie, and, in nine cases out of ten, a peculiarly tender condition of the prostate is discovered. It is, therefore, through the prostatic branches of the sympathetic that this disturbing influence acts. The indications of treatment are consequently obvious—viz., to allay the irritation; and, if its long continuance have induced muscular debility, to restore the lost tone. In the accomplishment of these objects, we must be guided by the severity of each case.

The prostatic irritation may in most cases be removed by the occasional passing of a catheter, perhaps once a week, or, in more urgent cases, by the application of caustic to the prostatic portion of the urethra, by one or other of the numerous instruments devised for this purpose. Nitrate of silver may be applied in a solid or fluid state; and so persuaded am I of the soundness of the views on which this practice is based, that I protest against the published opinions of recent writers on this subject, and assert that the practice, if judiciously performed, is attended with no risk whatever. I may remark that I prefer the application of the caustic in its fluid form. But, in a very large proportion of cases, this supposed extreme measure is not required: to accomplish the object in view, we possess the old medicinal agents above mentioned.

I shall select for illustration the two following cases, out of very many, to indicate the good results thus obtained.
